# Nurse's Drug Handbook

Twentieth Edition

**Mobile App  
Available!**

See back cover for details!

# Mechanism-of-Action Illustrations

Drugs with illustrated mechanisms of action	Drugs with similar mechanisms of action
isosorbide dinitrate, isosorbide mononitrate	nitroglycerin
lanthanum carbonate	sevelamer hydrochloride
linezolid	none
memantine hydrochloride	none
milrinone lactate	none
nateglinide	repaglinide
olmesartan medoxomil	irbesartan, losartan potassium, valsartan
omeprazole	esomeprazole magnesium, lansoprazole, pantoprazole sodium, rabeprazole sodium
orlistat	none
palonosetron hydrochloride	aloseptron, dolasetron, granisetron, ondansetron
phenelzine sulfate	isocarboxazid
spironolactone	none
tacrine hydrochloride	donepezil hydrochloride, galantamine hydrobromide, rivastigmine tartrate
teriparatide	none
vasopressin	desmopressin acetate
ziconotide	none

The content, statements, views, and opinions herein are the sole expression of the respective authors and not that of Jones & Bartlett Learning, LLC. Reference herein to any specific commercial product, process, or service by trade name, trademark, manufacturer, or otherwise does not constitute or imply its endorsement or recommendation by Jones & Bartlett Learning, LLC and such reference shall not be used for advertising or product endorsement purposes. All trademarks displayed are the trademarks of the parties noted herein. *2021 Nurse's Drug Handbook, Twentieth Edition* is an independent publication and has not been authorized, sponsored, or otherwise approved by the owners of the trademarks or service marks referenced in this product.

There may be images in this book that feature models; these models do not necessarily endorse, represent, or participate in the activities represented in

the images. Any screenshots in this product are for educational and instructive purposes only. Any individuals and scenarios featured in the case studies throughout this product may be real or fictitious, but are used for instructional purposes only.

The authors, editor, and publisher have made every effort to provide accurate information. However, they are not responsible for errors, omissions, or for any outcomes related to the use of the contents of this book and take no responsibility for the use of the products and procedures described. Treatments and side effects described in this book may not be applicable to all people; likewise, some people may require a dose or experience a side effect that is not described herein. Drugs and medical devices are discussed that may have limited availability controlled by the Food and Drug Administration (FDA) for use only in a research study or clinical trial. Research, clinical practice, and government regulations often change the accepted standard in this field. When consideration is being given to use of any drug in the clinical setting, the health care provider or reader is responsible for determining FDA status of the drug, reading the package insert, and reviewing prescribing information for the most up-to-date recommendations on dose, precautions, and contraindications, and determining the appropriate usage for the product. This is especially important in the case of drugs that are new or seldom used.

Newburgh, New York

**Sharon Kumm, RN, MN, CCRN**

Assistant Professor

School of Nursing

University of Kansas

Kansas City, Kansas

**Leanne McQuade, RN, BSN, CEN**

Staff Nurse  
Emergency Department  
Doylestown Hospital  
Case Manager  
CAB Medical Consultant  
Doylestown, Pennsylvania

**Pamela S. Ronning, RN, MPA**

Program Coordinator  
Kirkhof College of Nursing  
Grand Valley State University  
Allendale, Michigan

**Maureen Ryan, RN, CS, MSN, FNP**

Assistant Professor  
Grand Valley State University  
Allendale, Michigan  
Nurse Practitioner  
Emergency Department  
St. Mary's Hospital  
Grand Rapids, Michigan

**Julie M. Smith, RN, BA**

Staff Nurse  
Radiology-Heart Station  
Rancocas Hospital  
Willingboro, New Jersey

**Aaron J. Strehlow, RN, PhD, FNP**

Administrator and Director of Clinical Services  
UCLA School of Nursing  
Health Center at the Rescue Mission  
Los Angeles, California

**Maria Wilson, RN, MSN, CCRN**

Staff Nurse  
Emergency Department  
Chestnut Hill Hospital  
Philadelphia, Pennsylvania

# How to Use This Book

Jones & Bartlett Learning *Nurse's Drug Handbook* gives you what today's nurses and nursing students need: accurate, concise, and reliable drug facts. This book emphasizes the vital information you need to know before, during, and after drug administration. The information is presented in easy-to-understand language and organized alphabetically, so you can find what you need quickly.

## What's Special

In addition to the drug information you expect to find in each entry (see “Drug Entries” for details), the *Nurse's Drug Handbook* boasts these special features:

- **The design** makes it easy to find the most need-to-know drug information, such as indications, dosages, dosage adjustments, and warnings.
- **The size** makes the *Nurse's Drug Handbook* easy and convenient to carry and use.
- **Practical trim size** allows the book to open flat so you can find the information you need without wrestling with a book that wants to close. You can hold the book in one hand, see complete pages at a glance, and use your other hand to document or perform other activities.
- **Introductory material** reviews essential general information you need to know to administer drugs safely and effectively, including an overview of pharmacology and the principles of drug administration. In addition, the five steps of the nursing process are explained and related specifically to drug therapy.
- **Highly useful illustrations** throughout the text help you visualize selected mechanisms of action by showing how drugs work at the cellular,

tissue, and organ levels. In addition, the inside front cover features a table listing all the drugs whose mechanisms of action are illustrated, as well as other drugs with the same mechanisms of action.

- **No-nonsense writing style** speaks in everyday language and uses the terms and abbreviations you typically encounter in your practice and your studies. To avoid sexist language, we alternate between male and female pronouns throughout the book.
- **Up-to-date drug information** includes the latest FDA-approved drugs, new and changed indications, new warnings, and newly reported adverse reactions.
- **Dosage adjustment**, headlined in color, alerts you to expected dosage changes for a patient with a specific condition or disorder, such as advanced age or renal impairment.
- **Warning**, displayed in color, calls attention to important facts that you need to know before, during, and after drug administration. For example, in the alatrofloxacin entry, this feature informs you that the drug is usually reserved for hospitalized patients and is given for no more than 2 weeks because of the high risk of severe liver damage.
- **Easy-to-use tables** showing route, onset, peak, and duration (see page *xiii* for more details), and other tables in the appendices provide a time-saving way to track and check information. The appendices give you an overview of the most important facts and nursing considerations for important drug groups, including insulin preparations and oral allergen extracts, selected antihistamines, ophthalmics, topical drugs, antivirals, antineoplastic drugs, interferons, and antihypertensive combination drugs, as well as selected obstetrical drugs and vitamins. You'll also find handy instructions for calculating drug dosages and I.V. flow rates.

## Drug Entries

The *Nurse's Drug Handbook* clearly and concisely presents all the vital facts on the drugs that you'll typically administer. To help you find the information you need quickly, drug entries are organized alphabetically by generic drug name—from abatacept to zonisamide. For ease of use, every drug entry follows a consistent format. However, if specific details are unknown or don't apply, the heading isn't included so you can go right to the next section.

## **GENERIC AND TRADE NAMES**

First, each entry identifies the drug's main generic name, as well as alternate generic names. (For drugs prescribed by trade name, you can quickly check the comprehensive index, which refers you to the appropriate generic name and page.)

Next, the entry lists the most common U.S. trade names for each drug. It also includes common trade names available only in Canada, marked (CAN).

## **CLASS, CATEGORY, AND SCHEDULE**

Each entry lists the drug's pharmacologic and therapeutic classes. With this information, you can compare drugs in the same pharmacologic class but in different therapeutic classes, and vice versa.

The entry also lists the FDA's pregnancy risk category, which categorizes drugs based on their potential to cause birth defects. (For details, see *FDA pregnancy risk categories*.)

However, effective after June 30, 2015, new prescription drugs submitted to the FDA for approval will no longer be allowed to use the lettering system to categorize drugs based on their potential to cause birth defects. Instead, a new, more comprehensive text will be required in the label to explain the risks. Prescription drugs currently using the lettering system to identify potential for a drug to cause birth defects will be gradually phased into the new labeling requirement. Labeling of over-the-counter drugs will remain unchanged and is not affected by the FDA-mandated change.

Where appropriate, the entry also includes the drug's controlled substance schedule. (For details, see *Controlled substance schedules*, page xiii.)

# FDA pregnancy risk categories

Each currently prescribed drug may be placed in a pregnancy risk category based on the FDA's estimate of risk to the fetus. If the FDA hasn't provided a category, the *Nurse's Drug Handbook* notes that the drug is "Not classified." The categories range from A to X, signifying least to greatest fetal risk. Note that pregnancy risk categories will no longer be used in drug labeling for drugs approved after June 30, 2015, and existing drug labels that use the category will be gradually phased into the new labeling requirements.

## A Controlled studies show no risk

Adequate, well-controlled studies with pregnant women have failed to demonstrate a risk to the fetus in any trimester of pregnancy.

## B No evidence of risk in humans

Adequate, well-controlled studies with pregnant women haven't shown increased risk of fetal abnormalities, despite adverse findings in animals, or, in the absence of adequate human studies, animal studies show no fetal risk. The chance of fetal harm is remote, but remains possible.

## C Risk can't be ruled out

Adequate, well-controlled human studies are lacking, and animal studies have shown a risk to the fetus or are lacking as well. A chance of fetal harm exists if the drug is given during pregnancy, but the potential benefits may outweigh the risk.

## D Positive evidence of risk

Studies in humans, or investigational or postmarketing data, have shown fetal risk. Nevertheless, potential benefits from the drug's use may outweigh risks. For example, the drug may be acceptable if needed in a life-threatening situation or to treat a serious disease for which safer drugs can't be used or are ineffective.

## X Contraindicated in pregnancy

Studies in animals or humans, or investigational or postmarketing reports, have shown positive evidence of fetal abnormalities or risks that clearly

outweigh any possible benefit to the patient.

## Controlled substance schedules

The Controlled Substances Act of 1970 mandated that certain prescription drugs be categorized in schedules based on their potential for abuse. The greater their potential for abuse, the greater the restrictions on their prescription. The controlled substance schedules range from I to V, signifying highest to lowest abuse potential.

### I High potential for abuse

No accepted medical use exists for schedule I drugs, which include heroin and lysergic acid diethylamide (LSD).

### II High potential for abuse

Use may lead to severe physical or psychological dependence. Prescriptions must be written in ink or typewritten and must be signed by the prescriber. Oral prescriptions must be confirmed in writing within 72 hours and may be given only in a genuine emergency. No renewals are permitted.

### III Some potential for abuse

Use may lead to low-to-moderate physical dependence or high psychological dependence. Prescriptions may be oral or written. Up to five renewals are permitted within 6 months.

### IV Low potential for abuse

Use may lead to limited physical or psychological dependence. Prescriptions may be oral or written. Up to five renewals are allowed within 6 months.

### V Subject to state and local regulation

Abuse potential is low; a prescription may not be required.

## INDICATIONS AND DOSAGES

This section lists FDA-approved therapeutic indications. For each indication, you'll find the applicable drug form or route, age group (adults, adolescents, or children), and dosage (which includes amount per dose, timing, and duration, when known and appropriate).

## **ROUTE, ONSET, PEAK, AND DURATION**

Quick-reference tables show the drug's onset, peak, and duration (when known) for each administration route. The onset of action is the time a drug takes to be absorbed, reach a therapeutic blood level, and elicit an initial therapeutic response. The peak therapeutic effect occurs when a drug reaches its highest blood concentration and the greatest amount of drug reaches the site of action to produce the maximum therapeutic response. The duration of action is the amount of time the drug remains at a blood level that produces a therapeutic response.

## **MECHANISM OF ACTION**

This section concisely describes how a drug achieves its therapeutic effects at cellular, tissue, and organ levels, as appropriate. Illustrations of selected mechanisms of action lend exceptional clarity to sometimes complex processes.

## **INCOMPATIBILITIES**

In this section, you'll be alerted to drugs or solutions that are incompatible with the topic drug when mixed in a syringe or solution, or when infused through the same I.V. line.

## **CONTRAINDICATIONS**

An alphabetical list details the conditions and disorders that preclude administration of the topic drug.

## INTERACTIONS

This section includes drugs, foods, and activities (such as alcohol use and smoking) that can cause important, problematic, or life-threatening interactions with the topic drug. For each interacting drug, food, or activity, you'll learn the effects of the interaction.

## ADVERSE REACTIONS

Organized by body system, this section highlights common, serious, and life-threatening adverse reactions.

## NURSING CONSIDERATIONS

Warnings, general precautions, and key information that you must know before, during, and after drug administration are detailed in this section. Examples include whether a pill can be crushed and how to properly reconstitute, dilute, store, handle, or dispose of a drug.

### Teaching your patient about drug therapy

Your teaching about drug therapy will vary with your patient's needs and your practice setting. To help guide your teaching, each drug entry provides key information that you must teach your patient about that drug. For all patients, however, you also should:

- ✓ Teach the generic and trade name for each prescribed drug that he'll take after discharge—even if he took the drug before admission.
- ✓ Clearly explain why each drug was prescribed, how it works, and what it's supposed to do. To help your patient understand the drug's therapeutic effects, relate its action to her disorder or condition.
- ✓ Review the drug form, dosage, and route with the patient. Tell him whether the drug is a tablet, suppository, spray, aerosol, or other form, and explain how to take it correctly. Also, tell him how often to

take the drug and for what length of time. Emphasize that he should take the drug exactly as prescribed.

- ✓ Describe the drug's appearance, and explain that scored tablets can be broken in half for safe, accurate dosing. Warn the patient not to break unscored tablets, because doing so may alter the drug dosage. If your patient has trouble swallowing capsules, explain that she can open ones that contain sprinkles and take them with food or a drink but that she shouldn't do this with capsules that contain powder. Also, warn her not to crush or chew enteric-coated, extended-release, sustained-release, or similar drug forms.
- ✓ Teach the patient about common adverse reactions that may occur. Advise him to notify the prescriber at once if a dangerous adverse reaction, such as syncope, occurs.
- ✓ Warn her not to suddenly stop taking a drug if she's bothered by unpleasant adverse reactions, such as a rash and mild itching. Instead, encourage her to discuss the reactions with her prescriber, who may adjust the dosage or substitute a drug that causes fewer adverse reactions.
- ✓ Because drugs may cause adverse reactions (such as dizziness and drowsiness) that can impair the patient's ability to perform activities that require alertness, help him develop a dosing schedule that prevents these adverse reactions.
- ✓ Inform the patient which adverse reactions resolve with time.
- ✓ Teach the patient how to store the drug properly. Let him know if the drug is sensitive to light or temperature and how to protect it from these elements.
- ✓ Instruct the patient to store the drug in its original container, if possible, with the drug's name and dosage clearly printed on the label.
- ✓ Inform the patient which devices to use—and which to avoid—for drug storage or administration. For example, warn him not to take liquid cyclosporine with a plastic cup or utensils.
- ✓ Teach the patient what to do if she misses a dose. Generally, she should take a once-daily drug as soon as she remembers—provided that she remembers within the first 24 hours. If 24 hours have elapsed, she should take the next scheduled dose, but she should not double the dose. If she has questions or concerns about missed doses, tell her to contact the prescriber.
- ✓ Provide information specific to the prescribed drug. For example, if a patient takes a diuretic to manage heart failure, instruct him to weigh himself daily at the same time of day, using the same scale, and wearing the same amount of clothing. Or, if the patient takes digoxin

or an antihypertensive drug, teach him how to measure his pulse and blood pressure and how to record the measurements. Then instruct him to bring the diary to his regular appointments so the prescriber can monitor his response to the drug.

- ✓ Advise the patient to refill prescriptions promptly, unless she no longer needs the drug. Also instruct her to discard expired drugs because they may become ineffective or even dangerous over time.
- ✓ Warn the patient to keep all drugs out of the reach of children at all times.

Patient teaching information is also included here. You'll find important guidelines for patients, such as how and when to take each prescribed drug, how to spot and manage adverse reactions, which cautions to observe, when to call the prescriber, and more. To save your time, however, this section doesn't repeat basic patient-teaching points. (For a summary of those, see *Teaching your patient about drug therapy*, page xiv, and *Federal guidelines for drug disposal*)

New to this edition, life-threatening adverse reactions are now highlighted to draw attention to how serious the adverse reaction is.

In short, the Nurse's Drug Handbook is designed expressly to give you more of what you need. It puts vital drug information at your fingertips and helps you always stay current in this critical part of your practice or studies.

## Federal guidelines for drug disposal

Give patients these important instructions for properly disposing of their unwanted prescription drugs:

- ✓ Take unused, unneeded, or outdated prescription drugs out of their original containers and throw them in the trash.

- ✓ Consider mixing discarded prescription drugs with a substance like coffee grounds or used cat litter and putting them in impermeable, nondescript containers, such as empty cans or sealable bags.

---

- ✓ Flush prescription drugs down the toilet only if the label or accompanying patient information specifically tells you to do so.

---

- ✓ See if your community has a pharmaceutical take-back program that allows citizens to bring unused drugs to a central location for proper disposal.

---

# Foreword

Safe, effective drug therapy is one of your most important responsibilities. Not infrequently, a patient's life will depend on your ability to give drugs accurately and safely. In addition, you must keep up with the latest drug information, including newly approved drugs and recently reported life-threatening adverse reactions, as well as those drugs withdrawn from the market after widespread use.

Despite all the drug information available, medication errors remain one of the greatest threats to patients' well-being and a leading cause of lawsuits against nurses, physicians, and hospitals.

## **Your Responsibilities in Drug Therapy**

Your basic responsibilities in drug therapy include the following:

- Administer the right drug in the right dose by the right route at the right time to the right patient using the right preparation and administration.
- Know the therapeutic use, dosage, interactions, adverse reactions, and warnings of each administered drug.
- Be aware of newly approved drugs that may be prescribed.
- Know about changes to existing drugs, such as new indications and dosages and recently discovered adverse reactions and interactions.
- Concentrate fully when preparing and administering drugs.

- Respond promptly and appropriately to serious or life-threatening adverse reactions, interactions, and complications.
- Instruct each patient about the drug, how it's administered, which effects it causes or may cause, and which reactions to watch for and report.

Several factors may reduce your ability to meet these basic responsibilities—and contribute to medication errors. First, hospitals and other healthcare facilities have budget constraints that may result in elimination of professional nursing positions or the hiring of less qualified technicians to fill them. This forces the remaining nurses to care for more patients. Second, many hospital patients are older and more acutely ill, and they typically receive more complex drug therapy than ever. Together, these factors place greater demands on you—increasing your stress level, reducing the time you have to concentrate on drug administration, and increasing your risk of making medication errors or overlooking serious adverse reactions or interactions.

The same factors reduce your time and energy for learning the latest drug facts—which you need to have at your command. You must have this information at your fingertips because your next patient may need a recently approved drug or a complex and unfamiliar drug regimen.

How can you balance your limited time with your need to know the latest developments?

## **Meeting Your Needs**

Nurses and students need a reliable, accurate, easy-to-use, quick-reference drug book. They need a book clearly written by and for nurses that has been reviewed by experts in nursing and pharmacology. You hold such a book in your hands: the Nurse's Drug Handbook, with features that are always current.

The content of the Nurse's Drug Handbook was developed, written, and edited by experienced practicing nurses. Expert consultants, reviewers, and advisors—both nurses and pharmacists—help ensure the accuracy and reliability of the information covered in each entry and help target that information to your needs. What's more, every drug fact is checked against the most prominent drug references today, including the drug's package insert approved by the FDA, *American Hospital Formulary Service Drug Information*, *Drug Facts and Comparisons*, *The Physicians' Desk Reference*, the FDA's website of new drug approvals, and the USP DI's *Drug Information for the Health Care Professional*. In addition, to help you quickly access much-needed information, the book is organized alphabetically by generic drug name, follows a consistent format, and is concise.

To ensure that you're always current, the Nurse's Drug Handbook is updated every year. This newest edition contains:

- Important new drug entries in the main part of the book and in the appendices.
- New drug facts on hundreds of existing entries, including updated information on new indications and dosages, new incompatibilities and interactions, new adverse reactions, and new nursing considerations.
- Hundreds of patient-teaching guidelines and suggestions.

And as always, you'll find the same color-coded, highly readable type that reduces eyestrain as you speed to the information you need.

## **Getting More from Your Drug Reference Handbook**

Whether you currently work in or are preparing to work in acute care, home care, long-term care, or another healthcare setting, you'll want your own copy of the *Nurse's Drug Handbook*. That's because this book can help you:

- Reduce your risk of medication errors because you'll have easy access to accurate, reliable drug information that's relevant to your practice.
- Stay current on the most up-to-date drug developments of the year.
- Improve your drug administration skills and patient care before, during, and after drug therapy.
- Quickly detect and manage serious or life-threatening adverse reactions and complications or prevent them from occurring.
- Save time because you won't have to sift through volumes of information to find what you need, search for a book that's up-to-date, or look through several drug handbooks to get enough information.
- Increase your confidence about drug administration and enhance your professional interactions with other healthcare team members.
- Ensure the delivery of safe, effective care.
- Improve the depth and quality of your patient teaching.

## **Reaping the Rewards**

Your patients deserve the best and safest care possible—and you deserve to have the tools to deliver that care. Whether you're a student or an experienced clinician, the *Nurse's Drug Handbook* will help you provide safe, effective drug therapy because of its practical, easy-to-understand, accurate, and reliable information on virtually all the drugs you're likely to administer.

This handbook has aided thousands of nurses in their patient care. Take it with you to the clinical setting, share it with your peers, and use it to enhance your present and future position in the nursing profession.

Kathleen Dracup, RN, FNP, DNSc, FAAN

Dean and Professor

University of California, San Francisco

San Francisco, California

# Overview of Pharmacology

Understanding the basics of pharmacology is an essential nursing responsibility. Pharmacology is the science that deals with the physical and chemical properties, and biochemical and physiologic effects, of drugs. It includes the areas of pharmacokinetics, pharmacodynamics, pharmacotherapeutics, pharmacognosy, and toxicodynamics.

The *Nurse's Drug Handbook* deals primarily with pharmacokinetics, pharmacodynamics, and pharmacotherapeutics—the information you need to administer safe and effective drug therapy (discussed as follows). Pharmacognosy is the branch of pharmacology that deals with the biological, biochemical, and economic features of naturally occurring drugs. Toxicodynamics is the study of the harmful effects that excessive amounts of a drug produce in the body; in a drug overdose or drug poisoning, large drug doses may saturate or overwhelm normal mechanisms that control absorption, distribution, metabolism, and excretion.

## *Drug Nomenclature*

Most drugs are known by several names—chemical, generic, trade, and official—each of which serves a specific function. (See *How drugs are named*.) However, multiple drug names can also contribute to medication errors. You may find a familiar drug packaged with an unfamiliar name

if your institution changes suppliers or if a familiar drug is newly approved in a different dose or for a new indication.

### *Drug Classification*

Drugs can be classified in various ways. Most pharmacology textbooks group drugs by their functional classification, such as psychotherapeutics, which is based on common characteristics. Drugs can also be classified according to their therapeutic use, such as antipanic or antiobsessional drugs. Drugs within a certain therapeutic class may be further divided into subgroups based on their mechanisms of action. For example, the therapeutic class antineoplastics can be further classified as alkylating agents, antibiotic antineoplastics, antimetabolites, antimitotics, biological response modifiers, antineoplastic enzymes, and hormonal antineoplastics.

## How drugs are named

A drug's chemical, generic, trade, and official names are determined at different phases of the drug development process and serve different functions. For example, the various names of the commonly prescribed anticonvulsant divalproex sodium are:

- Chemical name: pentanoic acid, 2-propyl-, sodium salt (2:1), or  $(C_{16}H_{31}O_4Na)$
- Generic name: divalproex sodium
- Trade name: Depakote
- Official name: divalproex sodium delayed-release tablets, USP

A drug's chemical name describes its atomic and molecular structure. The chemical name of divalproex sodium—pentanoic acid, 2-propyl-, sodium salt (2:1), or  $C_{16}H_{31}O_4Na$  (pronounced valproate semisodium)—indicates that the drug is a combination of two valproic acid compounds with a sodium molecule attached to only one side.

Once a drug successfully completes several clinical trials, it receives a generic name, also known as the nonproprietary name. The generic name is usually derived from, but shorter than, the chemical name. The United States Adopted Names Council is responsible for selecting generic names, which are intended for unrestricted public use.

Before submitting the drug for FDA approval, the manufacturer creates and registers a trade name (or brand name) when the drug appears ready to be marketed. Trade names are copyrighted and followed by the symbol® to indicate that they're registered and that their use is restricted to the drug manufacturer. Once the original patent on a drug has expired, any manufacturer may produce the drug under its own trade name.

A drug's official name is the name under which it's listed in the United States Pharmacopoeia (USP) and the National Formulary (NF).

## Pharmacokinetics

Pharmacokinetics is the study of a drug's actions—or fate—as it passes through the body during absorption, distribution, metabolism, and excretion.

### ABSORPTION

Before a drug can begin working, it must be transformed from its pharmaceutical dosage form to a biologically available (bioavailable) substance that can pass through various biological cell membranes to reach its site of action. This process is known as absorption. A drug's absorption rate depends on its route of administration, its circulation through the tissue into which it's administered, and its solubility—that is, whether it's more water soluble (*hydrophilic*) or fat soluble (*lipophilic*).

Although drugs may penetrate cellular membranes either actively or passively, most drugs do so by *passive diffusion*, moving inertly from an area of higher concentration to an area of lower concentration. Passive diffusion may occur through water or fat. Passive diffusion through water—*aqueous diffusion*—occurs within large water-filled compartments, such as interstitial spaces, and across

epithelial membrane tight junctions and pores in the epithelial lining of blood vessels. Aqueous diffusion is driven by concentration gradients. Drug molecules that are bound to large plasma proteins, such as albumin, are too large to pass through aqueous pores in this way. Passive diffusion through fat—*lipid diffusion*—plays an important role in drug metabolism because of the large number of lipid barriers that separate the aqueous compartments of the body. The tendency of a drug to move through lipid layers between aqueous compartments often depends on the pH of the medium—that is, the ability of the water-soluble or fat-soluble drug to form weak acid or weak base.

Drugs with molecules that are too large to readily diffuse may rely on active *diffusion*, in which special carriers on molecules, including peptides, amino acids, and glucose, transport the drug through the membranes. However, some molecules with selective membrane carriers can expel foreign drug molecules; this is why many drugs can't cross the blood-brain barrier.

Drug absorption begins at the administration route. The three main administration route categories are enteral, parenteral, and transcutaneous. Depending on its nature or chemical makeup, a drug may be better absorbed from one site than from another.

### *Enteral Administration*

Enteral administration consists of the oral, nasogastric, and rectal routes.

*Oral:* Drugs administered orally are absorbed in the GI tract and then proceed by the hepatic portal vein to the liver and into the systemic circulation. Although generally considered the preferred route, oral drug administration has a number of disadvantages:

- The oral route doesn't always yield sufficiently high blood concentrations to be effective.
- Bioavailability may be less than optimal because of incomplete absorption and first-pass elimination (the part of metabolism that occurs during transit through the liver before the drug reaches the general circulation).
- Drug absorption may be incomplete if the drug is degraded by digestive enzymes or the acidic pH in the stomach or if it's excreted from the liver into the bile.
- Food in the GI tract, gastric emptying time, and intestinal motility may also impede drug absorption.

*Nasogastric:* Drugs administered through a nasogastric tube enter the stomach directly and are absorbed in the GI tract.

*Rectal:* Rectal drugs and suppositories also enter the GI tract directly after being inserted in the rectum and absorbed through the rectal mucosa. After being absorbed into the lower GI tract, rectal drugs enter the circulation through the inferior vena cava, bypassing the liver and thus avoiding first-pass metabolism. Suppositories, however, tend to travel upward into the rectum, where veins, such as the superior hemorrhoidal vein, lead to the liver. As a result, drug absorption by this route is often unreliable and difficult to predict.

### *Parenteral Administration*

Parenteral routes may be used whenever enteral routes are contraindicated or inadequate. These routes include intramuscular (I.M.), intravenous (I.V.), subcutaneous, and intradermal administration. Drug absorption is much faster and more predictable after parenteral administration than after enteral administration.

*I.M.:* Drugs administered by the I.M. route are injected deep into the muscle, where they're absorbed relatively quickly. The rate of drug absorption depends on the

vascularity of the injection site, the physiochemical properties of the drug, and the solution in which the drug is contained.

*I.V.:* I.V. drug administration involves injecting or infusing the drug directly into the blood circulation, allowing for rapid distribution throughout the body. This route usually provides the greatest bioavailability.

*Subcutaneous:* Drugs administered by the subcutaneous route are injected into the connective tissue just below the skin and are absorbed by simple diffusion from the injection site. The factors that affect I.M. absorption also affect subcutaneous absorption. Absorption by the subcutaneous route may be slower than by the I.M. route.

*Intradermal:* Drugs administered intradermally, such as purified protein derivative (PPD), are injected into the dermis, from which they diffuse slowly into the local microcapillary system.

### *Transcutaneous Administration*

Transcutaneous drug administration allows drug absorption through the skin or soft-tissue surface. Drugs may be inhaled, inserted sublingually, applied topically, or administered by the eyes, ears, nose, or vagina.

*Inhalation:* Inhaled drugs may be given as a powder and aerosolized or mixed in solution and nebulized directly into the respiratory tract, where they're absorbed through the alveoli. Inhaled drugs are usually absorbed quickly because of the abundant blood flow in the lungs, though some inhaled drugs have low systemic absorption.

*Sublingual:* Sublingual drug administration involves placing a tablet, troche, or lozenge under the tongue. The drug is absorbed across the epithelial lining of the mouth, usually quickly. This route avoids first-pass metabolism.

*Topical:* Topical drugs—creams, ointments, lotions, and patches—are placed on the skin and then cross the epidermis into the capillary circulation. They may also be absorbed through sweat glands, hair follicles, and other skin structures. Absorption by the skin is enhanced if the drug is in a solution.

*Ophthalmic:* Ophthalmic drugs include solutions and ointments that are instilled or applied directly to the cornea or conjunctiva as well as small, elliptical disks that are placed directly on the eyeball behind the lower eyelid. The movements of the eyeball promote distribution of these drugs over the surface of the eye. Although ophthalmic drugs produce a local effect on the conjunctiva or anterior chamber, some preparations may be absorbed systemically and therefore produce systemic effects.

*Otic:* Drops administered into the external auditory canal, otic drugs are used to treat infection or inflammation and to soften and remove ear wax. Otic solutions exert a local effect and may result in minimal systemic absorption with no adverse effects.

*Nasal:* Nasal solutions and suspensions are applied directly to the nasal mucosa by instillation or inhalation to produce local effects, such as vasoconstriction to reduce nasal congestion. Some nasal solutions, such as vasopressin, are administered by this route specifically to produce systemic effects.

*Vaginal:* Vaginal drugs include creams, suppositories, and troches that are inserted into the vagina, sometimes using a special applicator. These drugs are administered locally to treat such conditions as bacterial and fungal infections.

## **DISTRIBUTION**

Distribution is the process by which a drug is transported by the circulating fluids to various sites, including its sites of action. To ensure maximum therapeutic effectiveness, the drug must permeate all membranes that separate it from its intended site of action. Drug distribution is influenced by blood flow, tissue availability, and protein binding. Drugs that cannot distribute to the tissues in which they are needed are not effective.

## **METABOLISM**

Drug metabolism is the enzymatic conversion of a drug's structure into substrate molecules or polar compounds that are either less active or inactive and are readily excreted. Drugs can also be synthesized to larger molecules. Metabolism may also convert a drug to a more toxic compound. Because the primary site of drug metabolism is the liver, children, the elderly, and patients with impaired hepatic function are at risk for altered therapeutic effects.

*Biotransformation* is the process of changing a drug into its active metabolite. Compounds that require metabolic biotransformation for activation are known as *prodrugs*. During phase I of biotransformation, the parent drug is converted into an inactive or partially active metabolite. Much of the original drug may be eliminated during this phase. During phase II, the inactive or partially active metabolite binds with available substrates, such as acetic acid, glucuronic acid, sulfuric acid, or water, to form its active metabolite. When biotransformation leads to synthesis, larger molecules are produced to create a pharmacologic effect.

## **EXCRETION**

The body eliminates drugs by both metabolism and excretion. Drug metabolites—and, in some cases, the active

drug itself—are eventually excreted from the body, usually through bile, feces, and urine. The primary organ for drug elimination is the kidney. Impaired renal function may alter drug elimination, thereby altering the drug's therapeutic effect. Other excretion routes include evaporation through the skin, exhalation from the lungs, and secretion into saliva and breast milk.

A drug's elimination half-life is the amount of time required for half of the drug to be eliminated from the body. The half-life roughly correlates with the drug's duration of action and is based on normal renal and hepatic function. Typically, the longer the half-life, the less often the drug has to be given and the longer it remains in the body.

## **Pharmacodynamics**

Pharmacodynamics is the study of the biochemical and physiologic effects of drugs and their mechanisms of action. A drug's actions may be structurally specific or nonspecific. Structurally specific drugs combine with cell receptors, such as proteins or glycoproteins, to enhance or inhibit cellular enzyme actions. Drug receptors are the cellular components affected at the site of action. Many drugs form chemical bonds with drug receptors, but a drug can bond with a receptor only if it has a similar shape—much the same way that a key fits into a lock. When a drug combines with a receptor, channels are either opened or closed and cellular biochemical messengers, such as cyclic adenosine monophosphate or calcium ions, are activated. Once activated, cellular functions can be turned either on or off by these messengers.

Structurally nonspecific drugs, such as biological response modifiers, don't combine with cell receptors;

rather, they produce changes within the cell membrane or interior.

The mechanisms by which drugs interact with the body are not always known. Drugs may work by physical action (such as the protective effects of a topical ointment) or chemical reaction (such as an antacid's effect on the gastric mucosa), or by modifying the metabolic activity of invading pathogens (such as an antibiotic) or replacing a missing biochemical substance (such as insulin).

## **AGONISTS**

Agonists are drugs that interact with a receptor to stimulate a response. They alter cell physiology by binding to plasma membranes or intracellular structures. *Partial agonists* can't achieve maximal effects even though they may occupy all available receptor sites on a cell. *Strong agonists* can cause maximal effects while occupying only a small number of receptor sites on a cell. *Weak agonists* must occupy many more receptor sites than strong agonists to produce the same effect.

## **ANTAGONISTS**

Antagonists are drugs that attach to a receptor but don't stimulate a response; instead, they inhibit or block responses that would normally be caused by agonists. *Competitive antagonists* bind to receptor sites that are also compatible with an agonist, thus preventing the agonist from binding to the site. *Noncompetitive antagonists* bind to receptor sites that aren't occupied by an agonist; this changes the receptor site so that it's no longer recognized by the agonist. *Irreversible antagonists* work in much the same way that noncompetitive ones do, except that they permanently bind with the receptor.

Antagonism plays an important role in drug interactions. When two agonists that cause opposite therapeutic effects, such as a vasodilator and a vasoconstrictor, are combined, the effects cancel each other out. When two antagonists, such as morphine and naloxone, are combined, both drugs may become inactive.

## **Pharmacotherapeutics**

Pharmacotherapeutics is the study of how drugs are used to prevent or treat disease. Understanding why a drug is prescribed for a certain disease can assist you in prioritizing drug administration with other patient care activities. Knowing a drug's desired and unwanted effects may help you uncover problems not readily apparent from the admitting diagnosis. This information may also help you prevent such problems as adverse reactions and drug interactions.

A drug's *desired effect* is the intended or expected clinical response to the drug. This is the response you start to evaluate as soon as a drug is given. Dosage adjustments and the continuation of therapy often depend on your accurate evaluation and documentation of the patient's response.

An *adverse reaction* is any noxious and unintended response to a drug that occurs at therapeutic doses used for prophylaxis, diagnosis, or therapy. Adverse reactions associated with excessive amounts of a drug are considered drug overdoses. Be prepared to follow your institution's policy for reporting adverse drug reactions.

An *idiosyncratic response* is a genetically determined abnormal or excessive response to a drug that occurs in a particular patient. The unusual response may indicate that the drug has saturated or overwhelmed mechanisms that normally control absorption, distribution, metabolism, or

excretion, thus altering the expected response. You may be unsure whether a reaction is adverse or idiosyncratic. Once you report the reaction, the pharmacist usually determines the appropriate course of action.

An *allergic reaction* is an adverse response that results from previous exposure to the same drug or to one that's chemically similar to it. The patient's immune system reacts to the drug as if it were a foreign invader and may produce a mild hypersensitivity reaction, characterized by localized dermatitis, urticaria, angioedema, or photosensitivity. Allergic reactions should be reported to the prescriber immediately and the drug should be discontinued. Follow-up care may include giving drugs, including antihistamines and corticosteroids, to counteract the allergic response.

An *anaphylactic reaction* involves an immediate hypersensitivity response characterized by urticaria, pruritus, and angioedema. Left untreated, an anaphylactic reaction can lead to systemic involvement, resulting in shock. It's often associated with life-threatening hypotension and respiratory distress. Be prepared to assist with emergency life-support measures, especially if the reaction occurs in response to I.V. drugs, which have the fastest rate of absorption.

A *drug interaction* occurs when one drug alters the pharmacokinetics of another drug—for example, when two or more drugs are given concurrently. Such concurrent administration can increase or decrease the therapeutic or adverse effects of either drug. Some drug interactions are beneficial. For example, when taken with penicillin, probenecid decreases the excretion rate of penicillin, resulting in higher blood levels of penicillin. Drug interactions also may occur when a drug's metabolism is altered, often owing to the induction of or competition for

metabolizing enzymes. For example, H<sub>2</sub>-receptor agonists, which reduce secretion of the enzyme gastrin, may alter the breakdown of enteric coatings on other drugs. Drug interactions due to carrier protein competition typically occur when a drug inhibits the kidneys' ability to reduce excretion of other drugs. For example, probenecid is completely reabsorbed by the renal tubules and is metabolized very slowly. It competes with the same carrier protein as sulfonamides for active tubular secretion and so decreases the renal excretion of sulfonamides. This particular competition can lead to an increased risk of sulfonamide toxicity.

## **Special Considerations**

Although every drug has a usual dosage range, certain factors—such as a patient's age, weight, culture and ethnicity, gender, pregnancy status, and renal and hepatic function—may contribute to the need for dosage adjustments. When you encounter special considerations such as these, be prepared to reassess the prescribed dosage to make sure that it's safe and effective for your patient.

## **CULTURE AND ETHNICITY**

Certain drugs are more effective or more likely to produce adverse effects in particular ethnic groups or races. For example, blacks with hypertension respond better to thiazide diuretics than do patients of other races; on the other hand, blacks also have an increased risk of developing angioedema with angiotensin-converting enzyme (ACE) inhibitors. A patient's religious or cultural background also may call for special consideration. For example, a drug made from porcine products may be unacceptable to a Jewish or Muslim patient.

## **ELDERLY PATIENTS**

Because aging produces certain changes in body composition and organ function, elderly patients present unique therapeutic and dosing problems that require special attention. For example, the weight of the liver, the number of functioning hepatic cells, and hepatic blood flow all decrease as a person ages, resulting in slower drug metabolism. Renal function may also decrease with aging. These processes can lead to the accumulation of active drugs and metabolites as well as increased sensitivity to the effects of some drugs in elderly patients. Because they're also more likely to have multiple chronic illnesses, many elderly patients take multiple prescription drugs each day, thus increasing the risk of drug interactions.

## **CHILDREN**

Because their bodily functions aren't fully developed, children—particularly those under age 12—may metabolize drugs differently than adults. In infants, immature renal and hepatic functions delay metabolism and excretion of drugs. As a result, pediatric drug dosages are very different from adult dosages.

The FDA has provided drug manufacturers with guidelines that define pediatric age categories. Unless the manufacturer provides a specific age range, use these categories as a guide when administering drugs:

- neonates—birth up to age 1 month
- infants—ages 1 month to 2 years
- children—ages 2 to 12
- adolescents—ages 12 to 16.

## **PREGNANCY**

The many physiologic changes that take place in the body during pregnancy may affect a drug's pharmacokinetics and alter its effectiveness. Additionally, exposure to drugs may pose risks for the developing fetus. Before administering a drug to a pregnant patient, be sure to check its assigned FDA pregnancy risk category, or the new more comprehensive text for drugs approved after June 30, 2015, and intervene appropriately.

# Principles of Drug Administration

Because there are thousands of drugs and hundreds of facts about each one, taking responsibility for drug administration can seem overwhelming. One way that you can enhance your understanding of the principles of drug administration is to *associate*, *ask*, and *predict* during the critical thinking process. For example, associate each drug with general information you may already know about the drug or drug class. Ask yourself why a drug is administered by a certain route and why it's given multiple times throughout the day rather than only once. Learn to *predict* a drug's actions, uses, adverse effects, and possible drug interactions based on your knowledge of the drug's mechanism of action. As you apply these principles to drug administration, you'll begin to intuitively know which facts you need to make rational clinical decisions.

Prescriptions for patients in hospitals and other institutions typically are written by a physician on a form called the *physician's order sheet* or they're directly input into a computerized system with an electronic signature. Drugs are prescribed based not only on their specific mechanisms of action but also on the patient's profile, which commonly includes age, ethnicity, gender, pregnancy status, smoking and drinking habits, and use of other drugs.

## **“Rights” of Drug Administration**

Always keep in mind the following “rights” of drug administration: the right drug, right time, right dose, right patient, right route, and right preparation and administration.

## **RIGHT DRUG**

Many drugs have similar spellings, different concentrations, and several generic forms. Before administering any drug, compare the exact spelling and concentration of the prescribed drug that appears on the label with the information contained in the medication administration record or drug profile. Regardless of which drug distribution system your facility uses, you should read the drug label and compare it to the medication administration record at least three times:

- before removing the drug from the dispensing unit or unit dose cart
- before preparing or measuring the prescribed dose
- before opening a unit dose package (just before administering the drug to the patient).

## **RIGHT TIME**

Various factors can affect the time that a drug is administered, such as the timing of meals and other drugs, scheduled diagnostic tests, standardized times used by the institution, and factors that may alter the consistency of blood levels and drug absorption. Before administering any p.r.n. drug, check the patient’s chart to ensure that no one else has already administered it and that the specified time interval has passed. Also, document administration of a p.r.n. drug immediately.

## **RIGHT DOSE**

Whenever you're dispensing an unfamiliar drug or are in doubt about a dosage, check the prescribed dose against the range specified in a reliable reference. Be sure to consider any reasons for a dosage adjustment that may apply to your particular patient. Also, make sure you're familiar with the standard abbreviations your institution uses for writing prescriptions.

## **RIGHT PATIENT**

Always compare the name of the patient on the medication record with the name on the patient's identification bracelet. When using a unit dose system, compare the name on the drug profile with that on the identification bracelet.

## **RIGHT ROUTE**

Each drug prescription should specify the administration route. If the administration route is missing from the prescription, consult the prescriber before giving the drug. Never substitute one route for another unless you obtain a prescription for the change.

## **RIGHT PREPARATION AND ADMINISTRATION**

For drugs that need to be mixed, poured, or measured, be sure to maintain aseptic technique. Follow any specific directions included by the manufacturer regarding diluent type and amount and the use of filters, if needed. Clearly label any drug that you've reconstituted with the patient's name, the strength or dose, the date and time that you prepared the drug, the amount and type of diluent that you used, the expiration date, and your initials.

# **Administration Routes**

Drugs may be administered by a variety of routes and dosage forms. A particular route may be chosen for convenience or to maximize drug concentration at the site of action, to minimize drug absorption elsewhere, to prolong drug absorption, or to avoid first-pass metabolism.

Different dosage forms of the same drug may have different drug absorption rates, times of onset, and durations of action. For example, nitroglycerin is a coronary vasodilator that may be administered by the I.V., sublingual, oral, or buccal route, or as a topical ointment or disk. The I.V., sublingual, and buccal forms of nitroglycerin provide a rapid onset of action, whereas the oral, ointment, and disk forms have a slower onset and a prolonged duration of action.

Drug administration routes include the enteral, parenteral, and transcutaneous routes.

## **ENTERAL**

The enteral route consists of oral, nasogastric, and rectal administration. Drugs administered enterally enter the blood circulation by way of the GI tract. This route is considered the most natural and convenient route as well as the safest. As a result, most drugs are taken enterally, usually to provide systemic effects.

### *Oral*

- *Tablets:* Tablets, the most commonly used dosage form, come in a variety of colors, sizes, and shapes. Some tablets are specially coated for various purposes. Enteric coatings permit safe passage of a tablet through the stomach, where some drugs may be degraded or may produce unwanted effects, to the environment of the intestine. Some coatings protect the drug from the destructive influences of moisture, light, or air during storage; some coatings actually contain the drug, such as procainamide; still others conceal a bad taste. Coatings are also used to ensure

appropriate drug release and absorption. Some tablets shouldn't be crushed or broken because doing so may alter drug release.

- *Capsules:* Capsules are solid dosage forms in which the drug and other ingredients are enclosed in a hard or soft shell of varying size and shape. Drugs typically are released faster from capsules than from tablets.
- *Solutions:* Drugs administered in solution are absorbed more rapidly than many of those administered in solid form; however, they don't always produce predictable drug levels in the blood. Some drugs in solution should be administered with meals or snacks to minimize their irritating effect on the gastric mucosa.
- *Suspensions:* Suspensions are preparations consisting of finely divided drugs in a suitable vehicle, usually water. Suspensions should be shaken before administration to ensure the uniformity of the preparation and administration of the proper dosage.

### *Nasogastric*

Drugs administered through a nasogastric or gastrostomy tube enter the stomach directly, bypassing the mouth and esophagus. They're usually administered in liquid form because an intact tablet or capsule could cause an obstruction in a gastric tube. Sometimes a tablet may be crushed or a capsule opened for nasogastric administration; however, doing so will affect the drug's release. You may need to consult a pharmacist to determine which tablets can be crushed or capsules opened.

### *Rectal*

Some enteral drugs are administered rectally—as suppositories, solutions, or ointments—to provide either local or systemic effects. When inserted into the rectum, suppositories soften, melt, or dissolve, releasing the drug contained inside them. The rectal route may be preferred for drugs that are destroyed or inactivated by the gastric or intestinal environment or that irritate the stomach. It also may be indicated when the oral route is contraindicated because of vomiting or difficulty swallowing. The

drawbacks of rectal administration include inconvenience, noncompliance, and incomplete or irregular drug absorption.

## **PARENTERAL**

In parenteral drug administration, a drug enters the circulatory system through an injection rather than through GI absorption. This administration route is chosen when rapid drug action is desired; when the patient is uncooperative, unconscious, or unable to accept medication by the oral route; or when a drug is ineffective by other routes. Drugs may be injected into the joints, spinal column, arteries, veins, and muscles. However, the most common parenteral routes are the intramuscular (I.M.), intravenous (I.V.), subcutaneous (SubQ), and intradermal (I.D.) routes. Drugs administered parenterally may be mixed in either a solution or a suspension; those mixed in a solution typically act more rapidly than those mixed in a suspension. Parenteral administration has several disadvantages: The drug can't be removed or the dosage reduced once it has been injected, and injections typically are more expensive to administer than other dosage forms because they require strict sterility.

### *Intramuscular*

I.M. injections are administered deep into the anterolateral aspect of the thigh (vastus lateralis), the dorsogluteal muscle (gluteus maximus), the upper arm (deltoid), or the ventrogluteal muscle (gluteus medius). I.M. injections typically provide sustained drug action. This route is commonly chosen for drugs that irritate the subcutaneous tissue. The drug should be injected as far as possible from major nerves and blood vessels.

### *Intravenous*

In I.V. drug administration, an aqueous solution is injected directly into the vein—typically of the forearm. Drugs may be administered as a single, small-volume injection or as a slow, large-volume infusion. Because drugs injected I.V. don't encounter absorption barriers, this route produces the most rapid drug action, making it vital in emergency situations. Except for I.V. fat emulsions used as nutritional supplements, oleaginous preparations aren't usually administered by this route because of the risk of fat embolism.

### *Subcutaneous*

The subcutaneous route may be used to inject small volumes of medication, usually 1 ml or less. Subcutaneous injections typically are given below the skin in the abdominal area, lateral area of the anterior thigh, posterior surface of the upper arm, or lateral lumbar area. Injection sites should be rotated to minimize tissue irritation if the patient receives frequent subcutaneous injections—as, for example, in a patient who takes insulin.

### *Intradermal*

Common sites for intradermal injection are the arm and the back. Because only about 0.1 ml may be administered intradermally, this route is rarely used except in diagnostic and test procedures, such as screening for allergic reactions.

## **TRANSCUTANEOUS**

In transcutaneous administration, a drug crosses the skin layers from either the outside (dermal) or the inside (mucocutaneous). This route includes sublingual,

inhalation, ophthalmic, otic, nasal, topical, and vaginal administration.

### *Sublingual*

In sublingual administration, tablets are placed under the tongue and allowed to dissolve. Nitroglycerin is commonly administered by this route, which allows rapid drug absorption and action. The sublingual route also avoids first-pass metabolism.

### *Inhalation*

Some drugs may be inhaled orally or nasally to produce a local effect on the respiratory tract or a systemic effect. Although drugs given by inhalation avoid first-pass hepatic metabolism, the lungs can also serve as an area of first-pass metabolism by providing respiratory conversion to more water-soluble compounds.

### *Ophthalmic*

Ophthalmic solutions and ointments are applied directly to the cornea or conjunctiva for enhanced local penetration and decreased systemic absorption. These drugs usually are used in eye examinations and to treat glaucoma. Ophthalmic solutions pose a greater risk of drug loss through the nasolacrimal duct into the nasopharynx than ophthalmic ointments do.

### *Otic*

Otic solutions are instilled directly into the external auditory canal for local penetration and decreased systemic absorption. These drugs, which include anesthetics, antibiotics, and anti-inflammatory drugs, usually require occlusion of the ear canal with cotton after instillation.

### *Nasal*

Nasal solutions and suspensions are applied directly to the nasal mucosa for enhanced local penetration and decreased systemic absorption. These drugs are usually used to reduce the inflammation typically associated with seasonal or perennial rhinitis.

### *Topical*

Topical drugs—including creams, ointments, lotions, and pastes—are applied directly to the skin. Transdermal delivery systems, usually in the form of an adhesive patch or a disk, are among the latest developments in topical drug administration. Because they provide slow drug release, these systems are typically used to avoid first-pass metabolism and ensure prolonged duration of action.

### *Vaginal*

Vaginal troches, suppositories, and creams are inserted into the vagina for slow, localized absorption. Body pH that differs from blood pH causes drug trapping or reabsorption, which delays drug excretion through the renal tubules. Vaginal secretions are alkaline, with a pH of 3.4 to 4.2, whereas blood has a pH of 7.35 to 7.45.

# Drug Therapy and the Nursing Process

A systematic approach to nursing care, the nursing process helps guide you as you develop, implement, and evaluate your care and ensures that you'll deliver safe, consistent, and effective drug therapy to your patients. The nursing process consists of five steps, including assessment, nursing diagnosis, planning, implementation, and evaluation. Even though documentation is not a step in the nursing process, you're legally and professionally responsible for documenting all aspects of your care before, during, and after drug administration.

## **Assessment**

The first step in the nursing process, assessment involves gathering information that's essential to guide your patient's drug therapy. This information includes the patient's drug history, present drug use, allergies, medical history, and physical examination findings. Assessment is an ongoing process that serves as a baseline against which to compare any changes in your patient's condition; it's also the basis for developing and individualizing your patient's plan of care.

## **DRUG HISTORY**

The patient's drug history is critical in your planning of drug-related care. Ask about his previous use of over-the-

counter and prescription drugs, as well as herbal remedies. For each drug, determine:

- the reason the patient took it
- the prescribed dosage
- the administration route
- the frequency of administration
- the duration of the drug therapy
- any adverse reactions the patient may have experienced and how he handled them.

Also determine if the patient has a history of drug abuse or addiction. Depending on his physical and emotional state, you may need to obtain the drug history from other sources, such as family members, friends, other caregivers, and the medical record.

## **PRESENT DRUG USE**

Ask about the patient's current use of over-the-counter and prescription drugs, as well as herbal remedies. As you did in the drug history, find out the specific details for each drug (dosage, route, frequency, and reason for taking). Also ask the patient if he thinks the drug has been effective and when he took the last dose.

If the patient uses herbal remedies, similarly explore the use of these products, because herbs may interact with certain drugs. Also ask about the patient's use of recreational drugs, such as alcohol and tobacco, as well as illegal drugs, such as marijuana and heroin. If the patient acknowledges use of these drugs, be alert for possible drug interactions. This information also may provide you with insight about the patient's response—or lack of response—to his current drug treatment plan.

Try to find out if the patient has any other problems that might affect his compliance with the drug treatment plan, and intervene appropriately. For instance, a patient who is unemployed and has no health insurance may fail to fill a needed prescription. In such a case, contact an appropriate individual in your facility who may be able to help the patient obtain financial assistance.

Be sure to ask the patient if his drug treatment plan requires special monitoring or follow-up laboratory tests. For example, patients who take antihypertensives need to have their blood pressure checked routinely, and those who take warfarin must have their prothrombin time tested regularly. Other patients must undergo periodic blood tests to assess their hepatic and renal function. Determine whether the patient has complied with this part of his treatment plan, and ask him if he knows the results of the latest monitoring or laboratory tests.

## **ALLERGIES**

Find out if the patient is allergic to any drugs or foods. If he has an allergy, explore it further by determining the type of drug or food that triggers a reaction, the first time he experienced a reaction, the characteristics of the reaction, and other related information. Keep in mind that some patients consider annoying symptoms, such as indigestion, an allergic reaction. However, be sure to document a true allergy according to your facility's policy to ensure that the patient doesn't receive that drug or any related drug that may cause a similar reaction. Also, document allergies to foods because they may lead to drug interactions or adverse drug reactions. For example, sulfite is a food additive as well as a drug additive, so a patient with a known allergy to sulfite-containing foods is likely to react to sulfite-containing drugs.

## **MEDICAL HISTORY**

While reviewing your patient's medical history, determine if he has any acute or chronic conditions that may interfere with his drug therapy. Certain disorders involving major body systems, such as the cardiovascular, GI, hepatic, and renal systems, may affect a drug's absorption, transport, metabolism, or excretion and interfere with its action; they also may increase the incidence of adverse reactions and lead to toxicity. For each disorder identified, try to determine when the condition was diagnosed, what drugs were prescribed, and who prescribed them. This information can help you determine whether the patient is receiving incompatible drugs and whether more than one prescriber is managing his drug therapy.

Ask a female patient if she is or may be pregnant or if she is breastfeeding. Many drugs are safe to use during pregnancy, but others may harm the fetus. Also, some drugs are distributed into breast milk. If your patient is or might be pregnant, check the FDA's pregnancy risk category for the prescribed drug and notify the prescriber if the drug may pose a risk to the fetus. If the patient is breastfeeding, find out if the drug is distributed in breast milk and intervene appropriately.

## **PHYSICAL EXAMINATION FINDINGS**

As part of the physical examination, note the patient's age and weight. Be aware that age determines the dosage of certain drugs, such as sedatives and hypnotics, whereas weight determines the dosage of others, including some I.V. antibiotics and anticoagulants. As you perform the physical examination, note any abnormal findings that may point to body organ or system dysfunction. For example, if you detect liver enlargement and ascites, the patient may have impaired hepatic function, which can affect the

metabolism of a drug he's taking and lead to harmful adverse or toxic effects. Also note whether a body organ or system appears to be responding to drug treatment. For example, if a patient has been taking an antibiotic to treat chronic bronchitis, thoroughly evaluate his respiratory status to measure his progress. Be sure to assess the patient for possible adverse reactions to the drugs he's taking.

Assess the patient's neurologic function to make sure that he can understand his drug regimen and carry out required tasks, such as performing a fingerstick to obtain blood for glucose measurement. If the patient can't understand essential drug information, you'll need to identify a family member or another person who is willing to become involved in the teaching process.

## **Nursing Diagnosis**

Based on information derived from the assessment and physical examination findings, the nursing diagnoses are statements of actual or potential problems that a nurse is licensed to treat or manage alone or in collaboration with other members of the healthcare team. They're worded according to guidelines established by NANDA International.

One of the most common nursing diagnoses related to drug therapy is *knowledge deficit*, which indicates that the patient doesn't have sufficient understanding of his drug regimen. However, adverse reactions are the basis for most nursing diagnoses related to drug administration. For example, a patient receiving an opioid analgesic might have a nursing diagnosis of *constipation* related to decreased intestinal motility or *ineffective breathing* pattern related to respiratory depression. A patient receiving long-term, high-dose corticosteroids may have a risk for *impaired skin*

*integrity* related to cortisone acetate or *self-concept disturbance* related to physical changes from prednisone therapy. Many antiarrhythmics cause orthostatic hypotension and thus may place an elderly patient at *high risk for injury* related to possible syncope. Broad-spectrum antibiotics, especially penicillin, may lead to the overgrowth of *Clostridium difficile*, a bacterium that is normally present in the intestine. This overgrowth in turn may lead to pseudomembranous colitis, characterized by abdominal pain and severe diarrhea. The nursing diagnoses in such a case might include *potential for infection* related to bacterial overgrowth, *alteration in comfort* related to abdominal pain, and *fluid balance deficit* related to diarrhea.

## Planning

During the planning phase, you'll establish expected outcomes—or goals—for the patient and then develop specific nursing interventions to achieve them. Expected outcomes are observable or measurable goals that should occur as a result of nursing interventions and sometimes in conjunction with medical interventions. Developed in collaboration with the patient, the outcomes should be realistic and objective and should clearly communicate the direction of the plan of care to other nurses. They should be written as behaviors or responses for the patient, not the nurse, to achieve and should include a time frame for measuring the patient's progress. An example of a typical expected outcome is, *The patient will accurately demonstrate self-administration of insulin before discharge*. Based on each outcome statement you establish, you'd then develop appropriate nursing interventions, which might include drug administration techniques, patient teaching,

monitoring of vital signs, calculation of drug dosages based on weight, and recording of intake and output.

## **Implementation**

As you implement the nursing interventions, be sure to stringently follow the classic rule of drug administration: administer the right dose of the right drug by the right route to the right patient at the right time. Also, keep in mind that you have a legal and professional responsibility to follow institutional policy regarding standing orders, prescription renewal, and the use of nursing judgment. During the implementation phase, you'll also begin to evaluate the patient's expected outcomes and nursing interventions and make necessary changes to the plan of care.

## **Evaluation**

Evaluation is an ongoing process rather than a single step in the nursing process. During this phase, you evaluate each expected outcome to determine whether or not it has been achieved and whether the original plan of care is working or needs to be modified. In evaluating a patient's drug treatment plan, you should determine whether or not the drug is controlling the signs and symptoms for which it was prescribed. You also should evaluate the patient for psychological or physiologic responses to the drug, especially adverse reactions. This constant monitoring allows you to make appropriate and timely suggestions for changes to the plan of care, such as dosage adjustments or changes in delivery routes, until each expected outcome has been achieved.

# Documentation

You're responsible for documenting all your actions related to the patient's drug therapy, from the assessment phase to evaluation. Each time you administer a drug, document the drug name, dose, time given, and your evaluation of its effect. When you administer drugs that require additional nursing judgment, such as those prescribed on an as-needed basis, document the rationale for administering the drug and follow-up assessment or interventions for each dose administered.

If you decide to withhold a prescribed drug based on your nursing judgment, document your action and the rationale for it, and notify the prescriber of your action in a timely manner. Whenever you notify a prescriber about a significant finding related to drug therapy, such as an adverse reaction, document the date and time, the person you contacted, what you discussed, and how you intervened.

# A

## abacavir sulfate

**Ziagen**

### Class and Category

*Pharmacologic class:* Nucleoside reverse transcriptase inhibitor (NRTI)

*Therapeutic class:* Antiretroviral

### Indications and Dosages

- *As adjunct to treat human immunodeficiency virus (HIV) infection*

#### ORAL SOLUTION, TABLETS

**Adults.** 600 mg once daily or 300 mg twice daily in combination with other antiretroviral agents.

**Children, infants 3 months of age and over.** 16 mg/kg once daily or 8 mg/kg twice daily in combination with other antiretroviral agents. *Maximum:* 600 mg daily.

***DOSAGE ADJUSTMENT*** For patients with mild hepatic impairment, dosage reduced to 200 mg twice daily and only oral solution used to ensure accurate dosage.

### Mechanism of Action

Blocks an HIV enzyme called reverse transcriptase, which is responsible for starting or increasing the speed of a chemical reaction. By blocking this enzyme, HIV is prevented from multiplying.

## Contraindications

Hypersensitivity to abacavir or its components, moderate or severe hepatic impairment, presence of HLA-B\*5701 allele

## Interactions

### DRUGS

*methadone*: Possibly increased methadone clearance

## Adverse Reactions

**CNS:** Anxiety, chills, depression, dizziness, fatigue, fever, headache, lethargy, malaise, migraines, paresthesia, sleep disorders

**CV:** Edema, elevated triglyceride levels, **hypotension, MI**

**EENT:** Conjunctivitis, ENT infections, mouth ulcerations, pharyngitis

**ENDO:** Cushingoid appearance, fat redistribution, hyperglycemia

**GI:** Abdominal pain, diarrhea, elevated liver enzymes, gastritis, hyperamylasemia, **liver failure**, nausea, **pancreatitis, severe hepatomegaly with steatosis**, vomiting

**GU:** Renal dysfunction, **renal failure**

**HEME:** Anemia, **neutropenia**, **leukopenia**, **thrombocytopenia**

**MS:** Achiness, arthralgia, elevated CPK levels, musculoskeletal pain, myalgia, myolysis

**RESP:** **Adult respiratory distress syndrome**, bronchitis, cough, dyspnea, pneumonia, **respiratory failure**, viral respiratory infections

**SKIN:** **Erythema multiforme**, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other:** **Anaphylaxis**, **lactic acidosis**, lymphadenopathy, **multiorgan failure**, nonspecific pain

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug can cause fetal harm although it does cross the placental barrier.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection in HIV-negative infants or developing viral resistance in HIV- positive infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## Nursing Considerations

- Check to be sure patient has been screened for the HLA-B\*5701 allele prior to initiating abacavir therapy, because carriers of this allele are at greater risk of developing serious and sometimes fatal hypersensitivity reactions to abacavir.
- Know that a past medical history of an allergic reaction to abacavir, including any abacavir-containing product, is a contraindication for the use of abacavir therapy.
- Use caution when administering abacavir to patients with known risk factors for liver disease.
- Use cautiously in patients with coronary artery disease, because an increase in myocardial infarctions has occurred within 6 months of initiating abacavir therapy.
- Be aware that a scored tablet is available for pediatric patients weighing 14 kg or more, provided the child can swallow tablets.

**WARNING** Monitor patient closely for any hypersensitivity reaction. If present, notify prescriber immediately and expect drug to be discontinued, especially if a hypersensitivity reaction cannot be ruled out. Obesity, prolonged nucleoside exposure, and being a woman have been identified as risk factors. Know that a hypersensitivity reaction to abacavir usually presents with at least two of the following signs or symptoms: constitutional symptoms (achiness, fatigue, generalized malaise), fever, GI symptoms (abdominal pain, diarrhea, nausea, vomiting), rash, or respiratory symptoms (cough, dyspnea, pharyngitis). Other signs and symptoms that may be present include arthralgia, edema, headache, lethargy, myalgia, myolysis, and paresthesia. Know that adult respiratory distress syndrome, anaphylaxis, hypotension, renal failure, and respiratory failure have also occurred in association with an abacavir-induced hypersensitivity reaction and death has occurred.

- Monitor patient's liver enzymes periodically, as ordered, and monitor patient for any signs and symptoms of lactic acidosis or liver dysfunction

such as severe hepatomegaly with steatosis, which may become life-threatening. Be aware that incidence is higher in women and in the presence of obesity. If present, notify prescriber, and expect abacavir therapy to be discontinued even in the absence of marked transaminase elevations.

- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including abacavir. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus infection, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.
- Observe patient for redistribution of body fat, including breast enlargement, central obesity, development of buffalo hump, facial wasting, and peripheral wasting, which may produce a cushingoid-type appearance.

## PATIENT TEACHING

- Instruct patient/parents/caregiver to administer drug exactly as prescribed. If a dose is missed, have patient take it as soon as it is remembered. Stress importance of not doubling the next dose or taking more than the prescribed dose.

**WARNING** Review the warning card and medication guide with patient/parents/caregiver on how to recognize a hypersensitivity reaction. Stress importance of stopping abacavir at the first sign of a hypersensitivity reaction and notifying prescriber.

- Instruct patient/parents/caregiver on the signs and symptoms of lactic acidosis and liver dysfunction. Advise patient to stop taking abacavir if present and notify prescriber.
- Advise patient/parents/caregiver to inform prescriber of any signs or symptoms of an infection, as well as any unusual, persistent severe, or unusual adverse reactions.
- Instruct a mother not to breastfeed while she is receiving abacavir therapy.
- Warn patient that fat distribution may occur with abacavir therapy.

- Tell women of childbearing age to report a known or suspected pregnancy. Provide patient with information on pregnancy exposure registry, if pregnancy occurs.

# abaloparatide

**Tymlos**

## Class and Category

*Pharmacologic class:* Parathyroid hormone analogue

*Therapeutic class:* Antiosteoporotic

## Indications and Dosages

- *To treat postmenopausal women with osteoporosis who are at high risk for fracture, such as a history of multiple risk factors for fracture, have already sustained an osteoporotic fracture, or who have failed or are intolerant to other available osteoporosis therapy*

## SUBCUTANEOUS INJECTION

**Adult postmenopausal women.** 80 mcg once daily.

Route	Onset	Peak	Duration
SubQ	Unknown	0.51 min	Unknown

## Mechanism of Action

Acts as an agonist at the PTH1 receptor, which activates the cAMP signaling pathway in target cells to increase bone mineral density and content. This in turn increases bone strength at vertebral and/or nonvertebral sites.

## Contraindications

Hypersensitivity to abaloparatide or its components

## Interactions

### DRUGS

None

## Adverse Reactions

**CNS:** Dizziness, fatigue, headache, vertigo

**CV:** Orthostatic hypotension, palpitations, tachycardia

**GI:** Abdominal pain (upper), nausea

**GU:** Hypercalciuria, urolithiasis

**Other:** Antiabaloparatide antibodies, elevated uric acid levels, **hypercalcemia**, injection site reactions (severe edema, pain, redness)

## Childbearing Considerations

### PREGNANCY

- Drug is not indicated for use in females of reproductive potential.
- No human data with drug use in pregnant women is available.

### LACTATION

- Drug is not indicated for use in females that would be breastfeeding.
- There is no information on drug being present in breast milk, effects on the breastfed infant, or the effects on milk production.

## **Nursing Considerations**

- Know that abaloparatide and parathyroid hormone analogues such as teriparatide should not be given for more than 2 years cumulatively during patient's lifetime because of the potential risk of osteosarcoma.
- Be aware that abaloparatide should not be given to patients at increased risk for osteosarcoma. These risks include bone metastases or skeletal malignancies, hereditary disorders predisposing to osteosarcoma, open epiphyses, Paget's disease of bone or unexplained elevations of alkaline phosphatase, or prior external beam or implant radiation therapy involving the skeleton.
- Know that abaloparatide should not be given to women with preexisting hypercalcemia or who have an underlying hypercalcemic disorder, such as primary hyperparathyroidism, because of the risk of exacerbating hypercalcemia.
- Administer abaloparatide only as a subcutaneous injection into the periumbilical region of the abdomen at about the same time every day. Never give intramuscularly or intravenously. Rotate injection site daily. Give first several doses where patient can lie down or sit down, as orthostatic hypotension may occur.
- Monitor patient for orthostatic hypotension for at least 4 hours after each dose.
- Monitor patient's serum calcium levels, as ordered, because drug may increase calcium levels, causing hypercalcemia, hypercalciuria, and urolithiasis. If preexisting hypercalciuria or urolithiasis is suspected, expect to measure the patient's urinary calcium excretion, as ordered.
- Ensure that patient is receiving supplemental calcium and vitamin D if dietary intake is inadequate.

## **PATIENT TEACHING**

- Inform patient that abaloparatide should not be given more than 2 years cumulatively in patient's lifetime because of a potential risk for

osteosarcoma. Tell patient to immediately report persistent localized pain or occurrence of a new soft tissue mass that is tender to touch.

- Instruct patient or caregiver how to administer a subcutaneous injection using the abaloparatide pen and how to properly dispose of the needle and pen.
- Emphasize the importance of not sharing the drug or needles with others. Also tell patient not to transfer the contents of the pen to a syringe.
- Tell patient the pen must be discarded after 30 days of use, even if it still contains unused solution.
- Advise patient to change positions slowly for at least 4 hours after abaloparatide has been given and to watch for a drop in her blood pressure with position changes. Symptoms to be alert for include dizziness, nausea, or a rapid heart rate. If present, tell patient to lie down or sit until symptoms pass.
- Instruct patient to report signs and symptoms of high calcium levels such as constipation, lethargy, muscle weakness, nausea, or vomiting. Inform patient that she will need to have her calcium level checked routinely.
- Review dietary sources of calcium and vitamin D. Inform patient that calcium and vitamin D supplementation will be needed if dietary intake is insufficient.

**abatacept**

**Orencia**

## **Class and Category**

*Pharmacologic class:* Selective costimulation modulator

*Therapeutic class:* Antiarthritic (psoriatic, rheumatic)

## **Indications and Dosages**

- *To reduce signs and symptoms, induce major clinical response, inhibit progression of structural damage, and improve physical function in patients with moderate to severe active rheumatoid arthritis as monotherapy or concomitantly with disease-modifying antirheumatic drugs (DMARDs) other than tumor necrosis factor (TNF) antagonists; to treat active psoriatic arthritis*

## **I.V. INFUSION**

**Adults weighing more than 100 kg (220 lb).** *Initial:* 1,000 mg infused over 30 min, repeated at 2 and 4 wk after the first infusion and every 4 wk thereafter.

**Adults weighing 60 to 100 kg (132 to 220 lb).** *Initial:* 750 mg infused over 30 min, repeated at 2 and 4 wk after the first infusion and every 4 wk thereafter.

**Adults weighing less than 60 kg (132 lb).** *Initial:* 500 mg infused over 30 min, repeated at 2 and 4 wk after the first infusion and every 4 wk thereafter.

## **SUBCUTANEOUS INJECTION**

**Adults.** Following a single I.V. loading dose as per body weight categories listed above for treatment of rheumatoid arthritis, 125 mg given within a day, followed by 125 mg once wk. 125 mg once wk for treatment of rheumatoid arthritis when I.V. loading dose is not used or to treat psoriatic arthritis.

***DOSAGE ADJUSTMENT*** For patient transitioning from I.V. therapy to SubQ injection, first SubQ dose should be administered instead of the next scheduled I.V. dose.

- *To reduce signs and symptoms of moderate to severe active polyarticular juvenile idiopathic arthritis as monotherapy or concomitantly with methotrexate*

## **I.V. INFUSION**

**Children ages 6 to 17 weighing more than 100 kg (220 lb).** *Initial:* 1,000 mg infused over 30 min, repeated at 2 and 4 wk after the first infusion and every 4 wk thereafter.

**Children ages 6 to 17 weighing 75 to 100 kg (165 to 220 lb).** *Initial:* 750 mg infused over 30 min, repeated at 2 and 4 wk after the first infusion and every 4 wk thereafter.

**Children ages 6 to 17 weighing less than 75 kg (165 lb).** *Initial:* 10 mg/kg infused over 30 min, repeated at 2 and 4 wk after the first infusion and every 4 wk thereafter.

## **SUBCUTANEOUS INJECTION**

**Children age 2 and over weighing 50 kg (110 lb) or more.** 125 mg once wk.

**Children age 2 and over weighing 25 kg (55 lb) to less than 50 kg (110 lb).** 87.5 mg once wk.

**Children age 2 and over weighing 10 kg (22 lb) to less than 25 kg (55 lb).** 50 mg once wk.

## **Mechanism of Action**

Inhibits T-cell activation by binding to CD80 and CD86 to block interaction with CD28. CD28 is part of the costimulatory signal needed for full activation of T cells. Activated T cells have been implicated in the pathogenesis of rheumatoid arthritis. With decreased proliferation of T cells, inflammation and other evidence of rheumatoid arthritis decrease.

## **Incompatibilities**

Don't infuse abatacept solution with other drugs in the same intravenous line concurrently because it is not known

whether the drugs may interact.

## Contraindications

Hypersensitivity to abatacept or its components

## Interactions

### DRUGS

*live-virus vaccines*: Possibly decreased response to vaccine, and risk of infection with live virus

*tumor necrosis factor antagonists*: Increased risk of serious infection

## Adverse Reactions

**CNS**: Dizziness, fever, headache

**CV**: Hypertension, **hypotension**

**EENT**: Nasopharyngitis, rhinitis, sinusitis

**GI**: Abdominal pain, diarrhea, diverticulitis, dyspepsia, nausea

**GU**: **Acute pyelonephritis**, UTI

**MS**: Back or limb pain

**RESP**: Bronchitis, COPD worsening, cough, dyspnea, pneumonia, upper respiratory tract infection, wheezing

**SKIN**: Cellulitis, flushing, pruritus, rash, urticaria

**Other**: **Anaphylaxis**, antibody formation against abatacept, herpes simplex, herpes zoster infection, flu-like symptoms, **malignancies**, serious infections such as **sepsis**, varicella infection

# Childbearing Considerations

## PREGNANCY

- Pregnancy exposure registry: 1-877-311-8972.
- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Screen patient for latent tuberculosis with a tuberculin skin test before starting abatacept. If test is positive, expect to provide treatment, as ordered, before starting abatacept. Also screen patient for hepatitis B. If present, expect abatacept to be withdrawn because antirheumatic therapies such as abatacept may reactivate hepatitis B.
- Review patient's immunization record, and make sure all immunizations are current before therapy starts. Drug may blunt effectiveness of some vaccines and increase the risk of infection with live viruses.
- Use cautiously in patients with a history of recurrent infections, underlying conditions that may predispose them to infection, or existing chronic, latent, or localized infection. They have an increased risk of infection with abatacept therapy.
- Use cautiously in patients with COPD and monitor respiratory status closely because abatacept may worsen COPD and increase the risk of adverse respiratory reactions.
- Know that tumor necrosis factor antagonists shouldn't be given with abatacept because of an increased risk of serious infection.
- Prepare for I.V. injection, by reconstituting each vial with 10 ml of sterile water for injection, directing the stream of sterile water to the glass wall of the vial to minimize foaming. Use only the silicone-free disposable

syringe provided with each vial because a siliconized syringe may cause translucent particles to form in solution. Also use an 18- to 21-gauge needle. After injecting sterile water into vial, gently swirl vial until contents are completely dissolved. To minimize foaming, don't shake. Vent the vial with a needle to dissipate any foam that may be present.

- Dilute further the reconstituted solution with 0.9% sodium chloride injection to achieve a final solution volume of 100 ml. Slowly add solution into infusion bag or bottle using the same silicone-free disposable syringe provided with each vial. Mix gently. Do not shake the bag or bottle.
- Give I.V. dose after dilution over 30 minutes using an infusion set and a sterile, nonpyrogenic, low protein-binding filter with a pore size of 0.2  $\mu\text{m}$ .
- Be aware that once fully diluted, I.V. solution may be kept for 24 hours at room temperature or refrigerated. If reconstituted solution isn't used within 24 hours, discard.
- Watch patient closely for infusion-related reactions that may occur within 1 hour of the start of the infusion. Adverse reactions to be alert for include dizziness, headache, and hypertension. Less commonly a patient may experience cough, dyspnea, flushing, hypersensitivity, hypotension, nausea, pruritus, rash, and wheezing. Notify prescriber if present, but know that most patients need not discontinue abatacept because of these events unless severe.
- Administer subcutaneous injection using only the supplied 125 mg/ml single-dose prefilled glass syringe or the prefilled ClickJect autoinjector. Know that the 125 mg/syringe or autoinjector are never to be used for intravenous infusion.
- Rotate sites and never give in areas where the skin is tender, bruised, red, or hard.
- Monitor patient closely for evidence of hypersensitivity reaction such as dyspnea, pruritus, rash, urticaria, or wheezing after administering abatacept. If present, notify prescriber, and provide emergency care, as ordered.
- Monitor patient closely for evidence of infection or malignancy because abatacept inhibits T-cell activation, increasing the risk of both.

## **PATIENT TEACHING**

- Instruct patient receiving abatacept subcutaneously on how to administer the drug. Inform patient that injection sites should be rotated and should never be administered in an area where the skin is tender, bruised, red, or hard.

- Instruct patient self-administering abatacept subcutaneously to use a puncture-resistant container for disposal of needles and syringes. Have patient check with her community guidelines for correct way to dispose of a sharps container and stress the importance of not recycling the sharps container.
- Instruct patient not to receive immunizations with live vaccines during abatacept therapy and for 3 months afterward.
- Advise patient to tell prescriber of all medications being taken, including over-the-counter drugs and other biologic drugs.
- Emphasize need to report any evidence of infection or hypersensitivity to prescriber.
- Alert patient that abatacept may increase the risk of malignancy.
- Warn patient to avoid crowds and people with infections.
- Inform women to report known or suspected pregnancy. Encourage patient to register with the pregnancy exposure registry.

## acamprosate calcium

### Class and Category

*Pharmacologic class:* Amino acid neurotransmitter analogue

*Therapeutic class:* Alcohol deterrent

### Indications and Dosages

- *To maintain abstinence from alcohol for alcohol-dependent patients who are abstinent at the start of treatment*

### E.R. TABLETS

**Adults.** 666 mg three times daily.

**DOSAGE ADJUSTMENT** For patients with moderate renal impairment (creatinine clearance of 30 to 50 ml/min), initial dosage reduced to 333 mg three times daily.

Route	Onset	Peak	Duration
P.O.	Unknown	3–8 hr	Unknown

## Contraindications

Hypersensitivity to acamprosate or its components, severe renal impairment (creatinine clearance 30 ml/min or less)

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Abnormal thinking, amnesia, anxiety, asthenia, chills, depression, dizziness, headache, insomnia, paresthesia, somnolence, **suicidal ideation**, syncope, tremor

**CV:** Chest pain, hypertension, palpitations, peripheral edema, vasodilation

**EENT:** Abnormal vision, dry mouth, pharyngitis, rhinitis, taste perversion

**GI:** Abdominal pain, anorexia, constipation, diarrhea, flatulence, increased appetite, indigestion, nausea, vomiting

**GU:** **Acute renal failure**, decreased libido, impotence

**HEME:** **Leukopenia**, lymphocytosis, **thrombocytopenia**

**MS:** Arthralgia, back pain, myalgia

**RESP:** Bronchitis, cough, dyspnea

**SKIN:** Diaphoresis, pruritus, rash

**Other:** Flu-like symptoms, infection, weight gain

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm but animal studies suggest it may.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Know that acamprosate should start as soon as possible after patient has undergone alcohol withdrawal and achieved abstinence.
- Continue to give acamprosate even during periods of alcohol relapse, as ordered.

### **PATIENT TEACHING**

- Instruct patient to take acamprosate exactly as prescribed, even if a relapse occurs, and to seek help for a relapse.
- Tell patient to take tablet whole and not to crush, split, or chew it.
- Warn patient that acamprosate won't reduce symptoms of alcohol withdrawal if relapse occurs followed by cessation.

- Urge caregivers to monitor patient for evidence of depression (lack of appetite or interest in life, fatigue, excessive sleeping, difficulty concentrating) or suicidal tendencies because a small number of patients taking acamprosate have attempted suicide.
- Advise patient to use caution when performing hazardous activities until adverse CNS effects of drug are known.
- Tell female patient to notify prescriber if she is or intends to become pregnant while taking acamprosate; the drug may need to be stopped because fetal risks are unknown.

## Mechanism of Action

Chronic alcoholism may alter the balance between excitation and inhibition in neurons in the brain; acamprosate restores it.

When the neurotransmitter gamma-aminobutyric acid (GABA) binds to its receptors in the CNS, it opens the chloride ion channel and releases chloride ( $\text{Cl}^-$ ) into the cell (below left), thereby reducing neuronal excitability by inhibiting depolarization. By interacting with GABA receptor sites, acamprosate prevents GABA from binding (below right).

When glutamate binds to its receptors, it closes the chloride ion channel, increasing neuronal excitability by promoting depolarization (below left). This imbalance fosters a craving for alcohol. By interacting with glutamate receptor sites, acamprosate prevents glutamate from binding (below right).

## acetaminophen

**Oral or rectal: Abenol (CAN), Acephen, Actamin Maximum Strength, Actimol Children's (CAN), Actimol infant (CAN), Altenol, Aminofen, Apra, Atasol (CAN), Cetafen, Children's Mapap, Children's Nortemp, Dolono, Febrol, Feverall, Genapap, Genebs, Mapap,**

**Pediaphen (CAN), Pyrecot, Pyrigesic, Redutemp, Silapap, Tylenol, Tylenol 8-hr Arthritis Pain Caplets, Tylenol Extra Strength Caplets; Parenteral: Ofirmev**

## **Class and Category**

*Pharmacologic class:* Nonsalicylate, para-aminophenol derivative

*Therapeutic class:* Antipyretic, nonopioid analgesic

## **Indications and Dosages**

➤ *To relieve mild to moderate pain*

**REGULAR STRENGTH (325 MG): CAPLETS, CAPSULES, CHEWABLE TABLETS, ELIXIR, GELCAPS, LIQUID SOLUTION, SPRINKLES, SUSPENSION, TABLETS**

**Adults and children 12 yr and over.** 640 or 650 mg every 4 to 6 hr, as needed. *Maximum:* 3,250 mg (5 doses) in 24 hr.

**EXTRA STRENGTH (500 MG) CAPLETS OR TABLETS**

**Adults.** 1,000 mg every 6 hr, as needed. *Maximum:* 3,000 mg in 24 hr.

**8-HR (650 MG) CAPLETS**

**Adults.** 1,300 mg every 8 hr. *Maximum:* 3,900 mg in 24 hr.

## **CHEWABLE TABLETS, ORAL SUSPENSION, SYRUP**

**Children age 12 and over weighing 43.5 kg (96 lb) or more.** 640 mg every 4 hr, as needed. *Maximum:* 3,200 mg (5 doses) in 24 hr.

**Children age 11 weighing 32.6 kg (72 lb) to 43 kg (95 lb).** 480 mg every 4 hr, as needed. *Maximum:* 2,400 mg (5 doses) in 24 hr.

**Children age 9 to 10 weighing 27 kg (60 lb) to 32 kg (71 lb).** 400 mg every 4 hr, as needed. *Maximum:* 2,000 mg (5 doses) in 24 hr.

**Children age 6 to 8 weighing 21.5 kg (48 lb) to 26.5 kg (59 lb).** 320 mg every 4 hr, as needed. *Maximum:* 1,600 mg (5 doses) in 24 hr.

**Children age 4 to 5 weighing 16 kg (35 lb) to 21 kg (47 lb).** 240 mg every 4 hr, as needed. *Maximum:* 1,200 mg (5 doses) in 24 hr.

**Children age 2 to 3 weighing 10.9 kg (24 lb) to 15.9 kg (35 lb).** 160 mg every 4 hr, as needed. *Maximum:* 800 mg (5 doses) in 24 hr.

## **SUPPOSITORIES**

**Adults and adolescents.** 650 mg every 4 to 6 hr, as needed. *Maximum:* 3,900 mg in 24 hr.

**Children ages 6 to 12.** 325 mg every 4 to 6 hr, as needed. *Maximum:* 1,625 mg in 24 hr.

**Children ages 3 to 6.** 120 mg every 4 to 6 hr, as needed. *Maximum:* 600 mg in 24 hr.

**Children ages 1 to 3.** 80 mg every 4 to 6 hr, as needed. *Maximum:* 400 mg in 24 hr.

**Children ages 6 to 11 months.** 80 mg every 6 hr, as needed. *Maximum:* 320 mg in 24 hr.

- *To relieve mild to moderate pain; to manage moderate to severe pain with adjunctive opioid analgesics*

## **I.V. INFUSION (OFIRMEV)**

**Adults and adolescents age 13 and over weighing 50 kg (110 lb) or more.** 650 mg administered over 15 min every 4 hr, as needed, or 1,000 mg administered over 15 min every 6 hr, as needed. *Maximum:* 4,000 mg in 24 hr.

**Adults and children age 2 and over weighing less than 50 kg (110 lb).** 12.5 mg/kg administered over 15 min every 4 hr, as needed, or 15 mg/kg (up to 750 mg) administered over 15 min every 6 hr, as needed. *Maximum:* 75 mg/kg (up to 3,750 mg) in 24 hr.

- *To reduce fever*

## **I.V. INFUSION (OFIRMEV)**

**Adults and adolescents age 13 and over weighing 50 kg (110 lb) or more.** 650 mg administered over 15 min every 4 hr, as needed, or 1,000 mg administered over 15 min every 6 hr, as needed. *Maximum:* 4,000 mg in 24 hr.

**Adults and children age 2 and over weighing less than 50 kg (110 lb).** 12.5 mg/kg administered over 15 min every 4 hr, as needed, or 15 mg/kg (up to 750 mg) administered over 15 min every 6 hr, as needed. *Maximum:* 75 mg/kg (up to 3,750 mg) in 24 hr.

**Infants 29 days to 2 years.** 15 mg/kg every 6 hr, as needed. *Maximum:* 60 mg/kg/day with minimum dosing interval of 6 hr.

**Premature neonates at least 32 weeks gestational age and up to 28 days.** 12.5 mg/kg every 6 hr, as needed.

*Maximum:* 50 mg/kg/day with minimum dosing interval of 6 hr.

**DOSAGE ADJUSTMENT** For patient with severe renal impairment (creatinine clearance 30 ml/min or less), dosing interval increased and total daily dosage reduced. For patient with mild to moderate hepatic impairment, total daily dosage reduced.

Route	Onset	Peak	Duration
P.O., P.R., I.V.	Varies	1-3 hr	3-4 hr

## Mechanism of Action

Inhibits the enzyme cyclooxygenase, blocking prostaglandin production and interfering with pain impulse generation in the peripheral nervous system.

Acetaminophen also acts directly on temperature-regulating center in the hypothalamus by inhibiting synthesis of prostaglandin E<sub>2</sub>.

## Incompatibilities

Don't mix parenteral acetaminophen with any other medication. Diazepam and chlorpromazine are physically incompatible with parenteral acetaminophen.

## Contraindications

Hypersensitivity to acetaminophen or its components, severe hepatic impairment, severe active liver disease

## Interactions

### DRUGS

*anticholinergics*: Decreased onset of acetaminophen action  
*barbiturates, carbamazepine, hydantoins, isoniazid, rifampin, sulfinpyrazone*: Decreased therapeutic effects and increased hepatotoxic effects of acetaminophen  
*dasatinib, imatinib*: Possibly increased risk of hepatotoxicity  
*lamotrigine*: Possibly decreased therapeutic effects of these drugs  
*oral contraceptives*: Decreased effectiveness of acetaminophen  
*probenecid*: Possibly increased therapeutic effects of acetaminophen  
*propranolol*: Possibly increased action of acetaminophen  
*warfarin*: Possibly increased international normalized ratio  
*zidovudine*: Possibly decreased zidovudine effects

## **ACTIVITIES**

*alcohol use*: Increased risk of hepatotoxicity

## **Adverse Reactions**

**CNS**: Agitation, anxiety, fatigue, fever, headache, insomnia

**CV**: **Hypotension**, hypertension, peripheral edema

**EENT**: **Stridor (parenteral form)**

**ENDO**: **Hypoglycemic coma**

**GI**: Abdominal pain, constipation, diarrhea, **hepatotoxicity**, jaundice, nausea, vomiting

**GU**: Oliguria (parenteral form)

**HEME**: **Hemolytic anemia (with long-term use), leukopenia, neutropenia, pancytopenia, thrombocytopenia**

**MS:** Muscle spasm (parenteral form)

**RESP:** Parenteral form: **atelectasis**, dyspnea, plural effusion, **pulmonary edema**, wheezing

**SKIN:** **Acute generalized exanthematous pustulosis**, blisters, pruritus, rash, reddening, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, hypersensitivity reactions; for parenteral form: hypoalbuminemia, **hypokalemia**, **hypomagnesemia**, hypophosphatemia, injection-site pain

## Childbearing Considerations

### PREGNANCY

- Use of drug at any time during pregnancy may increase risk of attention deficit hyperactivity disorder (ADHD) after birth.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use acetaminophen cautiously in patients with hepatic impairment or active hepatic disease, alcoholism, chronic malnutrition, severe hypovolemia, or severe renal impairment.
- Know that before and during long-term therapy including parenteral therapy, liver function test results, including AST, ALT, bilirubin, and creatinine levels, as ordered must be monitored because acetaminophen

may cause hepatotoxicity. Ensure that the daily dose of acetaminophen from all sources does not exceed maximum daily limits.

- Monitor renal function in patient on long-term therapy. Keep in mind that blood or albumin in urine may indicate nephritis; decreased urine output may indicate renal failure; and dark brown urine may indicate presence of the metabolite phenacetin.
- Store suppositories under 26.6°C (80°F).

**WARNING** Do not confuse a dose in milligrams with a dose in milliliters when preparing and administering the parenteral form of acetaminophen. Also, make sure the dose is based on the patient's weight and infusion pumps are properly programmed.

- Be aware that patients weighing 50 kg (110 lb) or more and requiring 1,000-mg doses of parenteral acetaminophen (Ofirmev) can have the dose administered by inserting a vented intravenous set through the septum of the 100-ml vial. Further dilution is not required. For doses less than 1,000 mg, the appropriate dose must be withdrawn from the vial and placed into a separate container prior to administration to prevent inadvertent overdose. Place small-volume pediatric doses up to 60 ml in a syringe and administer over 15 minutes using a syringe pump.
- Monitor the end of a parenteral infusion to prevent possibility of air embolism.
- Use parenteral drug within 6 hours once vacuum seal of glass vial has been penetrated or contents transferred to another container.

**WARNING** Be aware that Pediaphen is a concentrated form of acetaminophen containing 80 mg/0.8 ml (standard liquid forms contain 32 mg/ml). Make sure to use correct concentration and dosage of liquid acetaminophen because serious adverse reactions can result from confusing concentrated form with regular liquid form.

## **PATIENT TEACHING**

- Tell patient that tablets may be crushed or swallowed whole.

- Know that concentrated infant drops are being phased out and are no longer manufactured, but may still be available.
- Instruct patient to read manufacturer's label and follow dosage guidelines precisely. Explain that infants' and children's acetaminophen liquid aren't equal in drug concentration and aren't interchangeable. Until concentrated infant drops are completely phased out, parents should use extra caution to ensure the correct dose is given with strength being used. Tell them to use only the measuring device that comes with the bottle to help ensure accurate dosage.
- Caution patient not to exceed recommended dosage or take other drugs containing acetaminophen at the same time because of risk of liver damage. Advise him to contact prescriber before taking other prescription or OTC products because they may contain acetaminophen.
- Teach patient to recognize signs of hepatotoxicity, such as bleeding, easy bruising, and malaise, which commonly occurs with chronic overdose.

**WARNING** Caution patient that serious skin reactions, although rare, may occur even with first-time use and any time acetaminophen is used, even if no skin reactions occurred with a previous use of drug. Tell patient that if a skin rash, redness, or blisters occur, he should stop using drug and seek emergency treatment immediately.

- Inform patient that acetaminophen may cause reduced fertility in both females and males.

**acetazolamide**  
**acetazolamide**  
**sodium**

## **Class and Category**

*Pharmacologic class:* Carbonic anhydrase inhibitor

*Therapeutic class:* Anticonvulsant, antiglaucoma, diuretic

## Indications and Dosages

- *To treat chronic simple (open-angle) glaucoma*

### **E.R. CAPSULES**

**Adults.** 500 mg twice daily.

### **I.V. INJECTION, TABLETS**

**Adults.** 250 to 1,000 mg daily (divided for doses exceeding 250 mg).

- *As short-term therapy to treat secondary glaucoma; to treat acute angle-closure glaucoma preoperatively when delay of surgery is needed in order to lower intraocular pressure*

### **E.R. CAPSULES**

**Adults.** 500 mg twice daily.

### **I.V. INJECTION, TABLETS**

**Adults.** 250 mg twice daily or every 4 hr; or 500 mg initially, followed by 125 to 250 mg every 4 hr for severe acute glaucoma. Oral therapy usually started after initial I.V. dose.

- *To treat edema caused by congestive heart failure*

### **I.V. INJECTION, TABLETS**

**Adults.** *Initial:* 250 to 375 mg or 5 mg/kg daily in morning. *Maintenance:* 250 to 375 mg or 5 mg/kg on alternate days or for 2 days followed by a drug-free day.

- *To treat drug-induced edema*

## **I.V. INJECTION, TABLETS**

**Adults.** 250 to 375 mg once daily for 1 to 2 days alternating with a day of rest.

- *To treat seizures, including generalized tonic-clonic, absence, and mixed seizures, and myoclonic jerk patterns*

## **I.V. INJECTION, TABLETS**

**Adults.** 8 to 30 mg/kg daily in divided doses. *Optimal:* 375 to 1,000 mg daily. When used with other anticonvulsants, initially, 250 mg daily, increased as needed to optimal dosage.

- *To prevent or relieve symptoms of acute mountain sickness*

## **E.R. CAPSULES, TABLETS**

**Adults.** 500 to 1,000 mg daily in divided doses, given 24 to 48 hr before ascent and continued for 48 hr or longer while at high altitude, as needed, to control symptoms.

Route	Onset	Peak	Duration
P.O. (E.R.)	2 hr	8-12 hr	18-24 hr
I.V.	2 min	15 min	4-5 hr

## **Mechanism of Action**

Inhibits the enzyme carbonic anhydrase, which normally appears in the eyes' ciliary processes, brain's choroid plexes, and kidneys' proximal tubule cells. In the eyes, enzyme inhibition decreases aqueous humor secretion,

which lowers intraocular pressure. In the brain, inhibition may delay abnormal, intermittent, and excessive discharge from neurons that cause seizures. In the kidneys, it increases bicarbonate excretion, which carries out water, potassium, and sodium, thus inducing diuresis and metabolic acidosis. This acidosis counteracts respiratory alkalosis and reduces symptoms of mountain sickness, including headache, dizziness, nausea, and dyspnea.

## Contraindications

Chronic noncongestive closed-angle glaucoma; cirrhosis; hyperchloremic acidosis; hypersensitivity to acetazolamide, sulfonamides, other sulfonamide derivatives, or their components; hypokalemia; hyponatremia; severe hepatic, renal, or adrenocortical impairment; suprarenal gland failure

## Interactions

### DRUGS

*amphetamines, phenobarbital, procainamide, quinidine:*

Decreased excretion and possibly toxicity of these drugs

*corticosteroids:* Increased risk of hypokalemia

*cyclosporine:* Increased cyclosporine level, possibly nephrotoxicity or neurotoxicity

*diflunisal:* Possibly significantly decreased intraocular pressure

*lithium:* Increased excretion and decreased effectiveness of lithium

*primidone:* Decreased serum and urine primidone levels

*salicylates:* Increased risk of salicylate toxicity

## Adverse Reactions

**CNS:** Ataxia, confusion, depression, disorientation, dizziness, drowsiness, fatigue, fever, flaccid paralysis, headache, lassitude, malaise, nervousness, paresthesia, **seizures**, tremor, weakness

**EENT:** Altered taste, tinnitus, transient myopia

**GI:** Anorexia, constipation, diarrhea, **hepatic dysfunction**, **melena**, nausea, vomiting

**GU:** Crystalluria, decreased libido, glycosuria, hematuria, impotence, **nephrotoxicity**, phosphaturia, polyuria, renal calculi, renal colic, urinary frequency

**HEME:** **Agranulocytosis**, **hemolytic anemia**, **leukopenia**, **pancytopenia**, **thrombocytopenia**, **thrombocytopenic purpura**

**SKIN:** Photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**, urticaria

**Other:** **Acidosis**, hyperuricemia, **hypokalemia**, weight loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm although animal studies suggest it might.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug may be present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

# Nursing Considerations

- Use acetazolamide cautiously in patients with calcium-based renal calculi, diabetes mellitus, gout, or respiratory impairment.
- Know that acetazolamide may increase risk of hepatic encephalopathy in patients with hepatic cirrhosis.
- Reconstitute each 500-mg vial with at least 5 ml sterile water for injection. Use within 12 hours because drug has no preservative unless refrigerated (use within 3 days).
- Monitor blood tests during acetazolamide therapy to detect electrolyte imbalances.
- Monitor fluid intake and output every 8 hours and body weight daily to detect excessive fluid and weight loss.

## PATIENT TEACHING

- Advise patient to avoid hazardous activities if dizziness or drowsiness occurs.
- Instruct patient who takes high doses of salicylates to notify prescriber immediately about evidence of salicylate toxicity, such as anorexia, tachypnea, and lethargy.
- Tell patient if she plans to mountain climb, urge her to descend mountain gradually and to seek immediate medical care if symptoms of mountain sickness occur.

**acetohydroxamic acid**

**Lithostat**

## Class and Category

*Pharmacologic class:* Urease inhibitor

*Therapeutic class:* Antagonist to bacterial enzyme urease

## Indications and Dosages

- *As an adjunct to antimicrobial therapy to treat chronic UTI caused by urea-splitting bacteria*

### TABLETS

**Adults.** *Initial:* 12 mg/kg daily in divided doses every 6 to 8 hr on an empty stomach. *Usual:* 250 mg three or four times daily for a total of 10 to 15 mg/kg daily. *Maximum:* 1,500 mg daily.

**Children.** *Initial:* 10 mg/kg daily in divided doses on an empty stomach, increased or decreased as tolerated and needed.

***DOSAGE ADJUSTMENT*** For a patient with a creatinine clearance level above 1.8 mg/dl, dosage interval increased to every 12 hours and maximum daily dosage decreased to 1 g.

## Mechanism of Action

Inhibits urease, the enzyme that catalyzes urea's hydrolysis to carbon dioxide and ammonia in urine infected with urea-splitting bacteria. This action reduces the urine ammonia level and pH, enhancing antimicrobial drug effectiveness.

## Contraindications

Contributing disorder that's treatable by surgery or appropriate antimicrobial therapy, hypersensitivity to acetohydroxamic acid or its components, inadequate renal function (serum creatinine level above 2.5 mg/dl or creatinine clearance below 20 ml/min), risk of pregnancy,

UTI caused by nonurease-producing organisms, UTI that could be controlled by appropriate antimicrobial therapy

## Interactions

### DRUGS

*iron:* Decreased intestinal absorption of iron, decreased effects of iron and acetohydroxamic acid

### ACTIVITIES

*alcohol use:* Increased risk of severe rash 30 to 45 minutes after drinking alcohol

## Adverse Reactions

**CNS:** Anxiety, depression, fever, headache, lack of coordination, malaise, nervousness, slurred speech, tiredness, tremor

**CV:** **Deep venous thrombosis**, palpitations, superficial phlebitis

**EENT:** Pharyngitis, sudden change in vision

**GI:** Anorexia, nausea, vomiting

**HEME:** **Hemolytic anemia**, reticulocytosis, **unusual bleeding**

**RESP:** Dyspnea, **pulmonary emboli**

**SKIN:** Ecchymosis, hair loss, nonpruritic macular rash

## Childbearing Considerations

### PREGNANCY

- Drug may cause serious fetal harm.
- Drug is contraindicated in a pregnant woman as well as any childbearing woman who is not using a reliable method of contraception.

## LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## REPRODUCTION

- Advise women of childbearing age to use a reliable method of contraception throughout drug therapy.

## Nursing Considerations

- Use acetohydroxamic acid cautiously in patients with anemia or chronic renal disease and those who've had phlebitis or thrombophlebitis.
- Be aware that risk of adverse psychomotor effects increases if patient drinks alcohol or takes drugs that affect alertness and reflexes, such as analgesics, antihistamines, narcotics, sedatives, and tranquilizers.

**WARNING** Be aware that acetohydroxamic acid chelates with dietary iron. If patient has iron deficiency anemia, expect to administer I.M. iron as needed during acetohydroxamic acid therapy.

- Monitor follow-up laboratory tests to check hepatic and renal function and urine pH, as ordered.

## PATIENT TEACHING

- Instruct patient to take drug at same time each day, as prescribed.

- Tell patient to take a missed dose up to 2 hours after scheduled time. If more than 2 hours have passed, he should wait for next scheduled dose and shouldn't double that dose.
- Warn patient not to take drug with alcohol or iron and to consult prescriber before taking it with any other drug.
- Instruct patient to avoid hazardous activities during therapy.

## acetylcysteine

**Acetadote, Acetylcysteine 10% or 20%, Parvolex (CAN)**

### Class and Category

*Pharmacologic class:* L-cysteine derivative

*Therapeutic class:* Antidote (for acetaminophen overdose), mucolytic

### Indications and Dosages

- *To liquefy abnormal, thickened, or viscid mucus secretions in chronic pulmonary disorders (including bronchiectasis, bronchitis, cystic fibrosis, and emphysema) and in pneumonia, pulmonary complications of cardiovascular or thoracic surgery, and tracheostomy care*

**SOLUTION BY DIRECT INSTILLATION INTO TRACHEOSTOMY (ACETYLCYSTEINE)**

**Adults and children.** 1 to 2 ml of 10% or 20% solution instilled every 1 to 4 hr, as needed.

## **SOLUTION BY INHALATION (ACETYLCYSTEINE)**

**Adults and children.** 1 to 10 ml of 20% solution or 2 to 20 ml of 10% solution nebulized through face mask, mouthpiece, or tracheostomy every 2 to 6 hr. *Usual:* 3 to 5 ml of 20% solution or 6 to 10 ml of 10% solution three or four times daily.

➤ *To treat acetaminophen overdose*

## **EFFERVESCENT TABLETS, SOLUTION P.O. (ACETYLCYSTEINE)**

**Adults and children.** *Loading dose:* 140 mg/kg.  
*Maintenance:* 70 mg/kg 4 hr after loading dose and then every 4 hr to a total of 17 doses.

## **I.V. INFUSION (ACETADOTE)**

**Adults and children weighing 41 kg (90.2 lb) or more.** 150 mg/kg in 200 ml of diluent infused over 60 min, followed by 50 mg/kg in 500 ml of diluent infused over 4 hr, followed by 100 mg/kg in 1,000 ml of diluent infused over 16 hr.

**Adults and children weighing 20 kg (44 lb) to 41 kg (90.2 lb)** 150 mg/kg in 100 ml of diluent infused over 60 min, followed by 50 mg/kg in 250 ml of diluent infused over 4 hr, followed by 100 mg/kg in 500 ml of diluent infused over 16 hr.

**Children weighing 5 kg (11 lb) to 20 kg (44 lb).** 150 mg/kg in 3 ml/kg of diluent infused over 60 min, followed by 50 mg/kg in 7 ml/kg of diluent infused over 4 hr, followed by 100 mg/kg in 14 ml/kg of diluent infused over 16 hr.

## Mechanism of Action

Decreases viscosity of pulmonary secretions by breaking disulfide links that bind glycoproteins in mucus. Reduces liver damage from acetaminophen overdose. Usually, acetaminophen's toxic metabolites bind with glutathione in the liver, which detoxifies them. When acetaminophen overdose depletes glutathione stores, toxic metabolites bind with protein in liver cells, killing them. Acetylcysteine maintains or restores levels of glutathione or acts as its substitute, which reduces liver damage from acetaminophen overdose.

## Incompatibilities

Don't give acetylcysteine with nebulization equipment if drug can contact copper, iron, or rubber. Don't give drug with amphotericin B, ampicillin sodium, chlortetracycline, chymotrypsin, erythromycin, hydrogen peroxide, iodized oil, oxytetracycline, tetracycline, or trypsin.

## Contraindications

Hypersensitivity to acetylcysteine or its components, no contraindications when used as antidote

## Interactions

### DRUGS

*activated charcoal:* Possibly adsorption and decreased effectiveness of oral acetylcysteine

*nitroglycerin:* Increased effects of nitroglycerin and possibly significant headache and hypotension

# Adverse Reactions

**CNS:** Chills, dizziness, drowsiness, fever, headache

**CV:** Edema, hypertension, **hypotension**, tachycardia

**EENT:** Rhinorrhea, stomatitis, **stridor**, tooth damage

**GI:** Anorexia, constipation, **hepatotoxicity**, nausea, vomiting

**RESP:** **Bronchospasm**, chest tightness, cough, **hemoptysis**, **respiratory distress**, shortness of breath, wheezing

**SKIN:** Clammy skin, erythema, facial flushing, pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding. Breastfeeding women may consider pumping and discarding their milk for 30 hours after drug administration.

# Nursing Considerations

- Know that acetylcysteine should be used cautiously in patients with asthma or a history of bronchospasm because drug may adversely affect respiratory function.

**WARNING** Treating acetaminophen overdose with intravenous therapy may require adjusting total administered volume, as ordered, for patients weighing less than 40 kg (88 lb) and for those who need fluid restriction, to avoid fluid overload and possibly fatal hyponatremia or seizures.

- Be aware that it may be necessary to dilute 20% inhalation or instillation solution with normal saline solution or sterile water when acetylcysteine is used to liquefy secretions. The 10% solution may be used undiluted.
- Follow guidelines for product prescribed when treating acetaminophen overdose. For example, dissolve appropriate number of 2.5 g and/or 500 mg effervescent tablets in water (for patients weighing 19 kg or less, dissolve in 100 ml of water; for patients weighing 20 to 60 kg, dissolve in 150 ml of water; and, for patients weighing 60 kg or more, dissolve in 300 ml of water). Once tablets are dissolved, administer oral solution immediately. For oral solution form (acetylcysteine), dilute 20% oral solution with cola or other soft drink to a concentration of 5%, and use within 1 hour.
- Dilute parenteral solution (Acetadote) with D<sub>5</sub>W or half-normal saline (0.45% sodium chloride) solution for injection following manufacturer guidelines because dilution is based on dosage. Acetadote may turn from colorless to slight pink or purple once the stopper is punctured, but color change has no effect on product quality.
- Keep in mind that acetylcysteine is most effective if given within 24 hours of acetaminophen ingestion. For specific instructions, contact a regional poison center at 1-800-222-1222 or a special health professional assistance hotline at 1-800-525-6115.
- Repeat dose as prescribed, if patient vomits loading dose or any maintenance dose within 1 hour of administration.
- Keep in mind that suicidal patient may not provide reliable information about vomiting. Watch such a patient to ensure that he ingests all of prescribed dosage.
- Watch for signs of hepatotoxicity (altered coagulation, easy bruising, and prolonged bleeding time), during treatment for acetaminophen overdose.

- Be aware that acetylcysteine may have a disagreeable odor, which disappears as treatment progresses.
- When drug is given intravenously, acute flushing and erythema of the skin may occur within 30 to 60 minutes of administration and often resolves spontaneously even with continued infusion of drug. However, monitor patient closely for acute hypersensitivity reactions regardless of form of drug administered, such as hypotension, rash, shortness of breath, and wheezing. If present, immediately stop administration of drug, notify prescriber, and provide supportive care according to protocol.
- Have patient wash his face and rinse his mouth at the end of each nebulization treatment because nebulization causes sticky residue on face and in mouth.
- Be aware that an open vial of solution may turn light purple but that this doesn't alter its effectiveness.
- Refrigerate opened vials and discard after 96 hours.
- Assess type, frequency, and characteristics of patient's cough. Particularly note sputum. If cough doesn't clear secretions, prepare to perform mechanical suctioning.
- Monitor patient for tachycardia.

## **PATIENT TEACHING**

- Tell patient receiving acetylcysteine intravenously that facial redness or flushing may occur but usually resolves on its own.
- Instruct patient to notify prescriber immediately about nausea, rash, or vomiting, as well as feeling dizzy or lightheaded, shortness of breath, or wheezing.
- Warn patient about acetylcysteine's unpleasant smell; reassure him that it subsides as treatment progresses.
- Urge patient prescribed drug to loosen mucus, to consume 2 to 3 L of fluid daily unless contraindicated by another condition, to decrease mucus viscosity.
- Instruct female patient who is breastfeeding to consider pumping and discarding her milk for 30 hours after acetylcysteine administration.

# acitretin

## Soriatane

### Class and Category

*Pharmacologic class:* Second-generation retinoid

*Therapeutic class:* Antipsoriatic

### Indications and Dosages

► *To treat severe psoriasis*

#### CAPSULES

**Adults.** 25 to 50 mg once daily with the main meal.

Route	Onset	Peak	Duration
P.O.	Unknown	2–5 hr	Unknown

### Mechanism of Action

Binds to several retinoid receptors to regulate gene transcription. Exactly how the action of this second-generation retinoid allows normal growth and development of skin is unknown.

### Contraindications

Alcohol consumption; blood donation; breastfeeding; chronic hyperlipidemia; concurrent use of etretinate, methotrexate, or tetracycline; hypersensitivity to acitretin,

other retinoids, or their components; pregnancy; severe hepatic or renal impairment

## Interactions

### DRUGS

*methotrexate*: Increased risk of hepatitis

*oral contraceptives containing only progestin*: Possibly decreased effectiveness of oral contraceptive

*phenytoin*: Possibly decreased protein binding of phenytoin

*sulfonylureas*: Possibly increased risk of hypoglycemia

*tetracyclines*: Possibly increased intracranial pressure

*vitamin A and other oral retinoids*: Increased risk of hypervitaminosis A

### ACTIVITIES

*alcohol use*: Increased risk of adverse reactions and acitretin toxicity

## Adverse Reactions

**CNS**: Aggression, **CVA**, depression, fatigue, headache, hyperesthesia, hypotonia, insomnia, **intracranial hypertension**, paresthesia, peripheral neuropathy, rigors, somnolence, **suicidal ideation**, thirst

**CV**: Chest pain, decreased high-density lipoproteins, edema, elevated cholesterol or triglyceride levels, **MI**, **thromboembolism**

**EENT**: Abnormal or blurred vision, blepharitis, conjunctivitis, corneal epithelial abnormality, decreased night vision, deafness, dry eyes or mouth, earache, epistaxis, eye pain, gingival bleeding, gingivitis, increased

saliva, photophobia, sinusitis, stomatitis, taste perversion, tinnitus, ulcerative stomatitis

**ENDO:** Hot flashes, hyperglycemia

**GI:** Anorexia, abdominal pain, diarrhea, elevated liver enzymes, **hepatitis**, **hepatotoxicity**, nausea, **pancreatitis**

**GU:** Vulvovaginitis

**HEME:** **Capillary leak syndrome**, **hemorrhage**, **increased bleeding time**

**MS:** Arthralgia, arthrosis, back pain, hyperostosis, myalgia, myopathy

**SKIN:** Abnormal skin or hair texture, alopecia, bullous eruption, cold or clammy skin, dermatitis, diaphoresis, dry or peeling skin, erythematous rash, **exfoliative dermatitis**, erythroderma, flushing, fragility or thinning of skin, loss of eyelashes or eyebrows, photosensitivity, pruritus, purpura, pyogenic granuloma, rash, scaling, seborrhea, skin fissure or ulceration

**Other:** **Hypervitaminosis A**, increased appetite

## Childbearing Considerations

### PREGNANCY

- Drug causes fetal harm, especially severe fetal malformations.
- Drug is contraindicated in pregnant women and women of childbearing age who are not using reliable contraception.
- Patient of child bearing age must meet all of the following conditions before drug can be prescribed:
  - 2 negative urine or serum pregnancy tests with a sensitivity of at least 25 mIU/ml; first test done before initial prescription of drug and second test done during the first 5 days of the menstrual cycle

immediately preceding the 7 days before drug therapy actually begins.

- A negative pregnancy test before prescription is refilled monthly.
  - Patient agrees to have a pregnancy test done every 3 months for at least 3 years after drug is discontinued.
  - Patient has selected and is committed to using 2 effective forms of contraception simultaneously, for at least 1 month prior to drug therapy beginning, throughout drug therapy, and for at least 3 years after drug is discontinued.
  - Patient agrees to use at least 1 contraceptive of a primary form, unless absolute abstinence is the chosen method, patient has undergone a hysterectomy, or is clearly postmenopausal.
  - Patient makes a commitment to undergo counseling about contraception and behaviors associated with an increased risk of pregnancy on a monthly basis and every 3 months for at least 3 years following drug being discontinued.
- Patient agrees to participate in the “Do Your P.A.R.T.” (Pregnancy Prevention Actively required During and After Treatment) program.
  - Patient understands drug may interfere with the contraceptive effect of microdosed progestin preparations and knows that the microdosed “minipill” is not recommended for use with the drug.
  - Patient expresses an understanding that it is not known if there is an interaction between the drug and combined oral contraceptives.
  - Patient agrees not to use St. John’s Wort during drug therapy and for at least 3 years following the discontinuation of the drug because pregnancies have occurred in users of combined hormonal contraceptives and St. John’s Wort.
  - Patient agrees not to donate blood during and for at least 3 years following the completion of drug therapy because women of childbearing potential must not receive blood from patients being treated with drug.

## **LACTATION**

- Drug may be present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## REPRODUCTION

- Pregnancy must be avoided.
- Advise patient to use reliable contraception for at least one month before, during drug therapy, and for at least 3 years following drug discontinuation as outlined above.

## Nursing Considerations

**WARNING** Don't give acitretin to a pregnant woman, a woman contemplating pregnancy, or a woman who may not use reliable contraception during drug therapy and for at least 3 years afterward because acitretin causes major fetal abnormalities.

- Make sure patient has had 2 negative urine or serum pregnancy tests with a sensitivity of at least 25 mIU/ml before receiving acitretin. First test should be obtained when decision is made to use acitretin and second test during first 5 days of the menstrual period just before acitretin therapy starts. For patients with amenorrhea, second test should be done at least 11 days after the last act of unprotected sexual intercourse (which means without using two effective forms of contraception simultaneously).
- Check to make sure female patient of childbearing age has signed the patient agreement and informed consent form before starting acitretin therapy.
- Obtain a lipid profile, as ordered, before acitretin therapy starts and every 1 to 2 weeks for up to 8 weeks or until lipid effects are known. In high-risk patients, such as those with diabetes, obesity, or a history of alcohol abuse and those taking acitretin long-term, check lipid profile periodically throughout therapy.
- Monitor liver enzymes, as ordered. If hepatotoxicity is suspected, expect to stop drug and investigate cause.
- Monitor patient closely for capillary leak syndrome demonstrated by localized or generalized edema, weight gain, fever, hypotension, and myalgias. If present, notify prescriber and expect to obtain laboratory studies for evidence of neutrophilia, hypoalbuminemia, and an elevated hematocrit. If confirmed, discontinue acitretin therapy, as ordered.

- Prepare patient for periodic bone radiography if she takes acitretin long term or she develops a skeletal disorder because ossification abnormalities can occur, especially of the vertebral column, knees, and ankles.
- Monitor patient's eyes for abnormalities throughout therapy. Expect patient to stop drug and have an ophthalmologic examination if eye abnormalities occur.
- Monitor patient for evidence of increased intracranial pressure, such as papilledema, headache, nausea, vomiting, and visual disturbances. If papilledema occurs, stop drug therapy immediately and obtain a neurologic evaluation, as ordered. Patient should never receive a tetracycline while taking acitretin because combined use can increase intracranial pressure.
- Assess patient for suicidal ideation because depression and other psychiatric symptoms, including thoughts of self-harm, may occur with acitretin use. Expect drug to be discontinued if psychiatric symptoms develop.
- Be aware that significantly lower doses of phototherapy are needed during acitretin therapy because drug increases the risk of erythema. If patient develops serious skin reactions, notify prescriber and expect acitretin therapy to be discontinued.

## PATIENT TEACHING

**WARNING** Warn women of childbearing age that acitretin causes major fetal abnormalities.

- Inform woman of childbearing age that she must have a pregnancy test before acitretin therapy starts, every month during acitretin therapy, and every 3 months for 3 years after therapy stops.
- Emphasize to woman of childbearing age that she must use two effective forms of contraception simultaneously unless she has chosen absolute abstinence or has had a hysterectomy. This must begin at least 1 month before acitretin therapy starts and continue throughout therapy and for at least 3 years after therapy ends.
- Caution women taking oral contraceptives that some prescribed and OTC drugs, including herbal supplements such as St. John's wort, may interfere with oral contraceptives. Urge her to tell prescriber about all drugs she takes.

- Alert female patient of childbearing age that any method of birth control can fail, including tubal ligation, and that microdose progestin “minipill” preparations are not recommended to be taken with acitretin. Tell her to seek immediate medical care on how to obtain emergency contraception if sexual intercourse occurs without using 2 effective forms of contraception simultaneously.
- Caution patient not to consume alcohol or products that contain alcohol during acitretin therapy and for 2 months after therapy ends.
- Inform patient that regular blood tests will be needed to monitor liver function. Tell him to notify prescriber if any of the following develops: nausea and vomiting, loss of appetite, dark urine, or whites of eyes or skin turns yellow.
- Warn patient, male or female of any age, not to donate blood during acitretin therapy and for at least 3 years after it ends.
- Review acitretin medication guide with patient, and answer the patient’s questions.
- Inform patient that psoriasis may worsen during initial treatment and that full effects of drug may not be seen for up to 3 months.
- Caution patient to avoid hazardous activities until drug’s CNS and ophthalmic effects are known.
- Inform patient that tolerance to contact lenses may decrease during acitretin therapy and for a period of time after treatment ends.
- Advise patient not to take more than the minimum recommended daily allowance of vitamin A during acitretin therapy because of the risk of vitamin A toxicity.
- Caution patient not to use sun lamps and to avoid excessive exposure to sunlight because the effects of UV light are enhanced by retinoids such as acitretin.
- Tell patient to notify prescriber of any new skin changes that become serious or prolonged, as acitretin therapy may need to be discontinued, if present.

## acyclovir

### Sitavig, Zovirax

# acyclovir sodium

**Zovirax I.V.**

## Class and Category

*Pharmacologic class:* Nucleoside analogue

*Therapeutic class:* Antiretroviral

## Indications and Dosages

- *To treat initial episodes of herpes genitalis*

### **CAPSULES, ORAL SUSPENSION, TABLETS**

**Adults.** 200 mg every 4 hr, 5 times daily for 10 days.

### **OINTMENT 5%**

**Adults.** Applied to completely cover all lesions (about ½-inch ribbon of ointment per 4 square inches of surface area) every 3 hr, 6 times daily for 7 days.

- *To treat severe initial episodes of herpes genitalis*

### **I.V. INFUSION**

**Adults and adolescents.** 5 mg/kg infused at a constant rate over 1 hr, every 8 hr for 5 days.

- *To suppress unusually frequent recurrent episodes of herpes genitalis (6 or more episodes per year)*

### **CAPSULES, ORAL SUSPENSION, TABLETS**

**Adults.** 200 mg 3 times daily, increased if breakthrough occurs up to 200 mg, 5 times daily. Alternatively, 400 mg twice daily.

- *To treat recurrent episodes of herpes genitalis intermittently*

## **CAPSULES, ORAL SUSPENSION, TABLETS**

**Adults.** 200 mg every 4 hr, 5 times daily for 5 days.

- *To treat recurrent herpes labialis in immunocompetent patients*

## **BUCCAL TABLETS (SITAVIG)**

**Adults.** 50 mg as a single dose to the upper gum region applied within 1 hr after onset of prodromal symptoms and before the appearance of any signs of herpes labialis.

## **CREAM 5%**

**Adults and adolescents.** Applied 5 times daily for 4 days and initiated as soon as possible following onset of signs and symptoms.

- *To treat non-life-threatening mucocutaneous Herpes simplex virus infections in immunocompromised patients*

## **OINTMENT 5%**

**Adults.** Applied to completely cover all lesions (about ½-inch ribbon of ointment per 4 square inches of surface area) every 3 hr, 6 times daily for 7 days.

- *To treat cutaneous and mucosal herpes simplex (HSV-1 and HSV-2) infections in immunocompromised patients*

## **I.V. INFUSION**

**Adults and adolescents.** 5 mg/kg infused at a constant rate over 1 hr, every 8 hr for 7 days.

**Infants and children 3 months to 12 years.** 10 mg/kg infused at a constant rate over 1 hr, every 8 hr for 7 days.

➤ *To treat herpes simplex encephalitis*

## **I.V. INFUSION**

**Adults and adolescents.** 10 mg/kg infused at a constant rate over 1 hr, every 8 hr for 10 days.

**Children 3 months to 12 years.** 20 mg/kg infused at a constant rate over 1 hr, every 8 hr for 10 days.

➤ *To treat neonatal herpes simplex virus infections*

## **I.V. INFUSION**

**Neonates postmenstrual age of at least 34 weeks.** 20 mg/kg infused at a constant rate over 1 hr, every 8 hr for 21 days.

**Neonates postmenstrual age of less than 34 weeks.** 20 mg/kg infused at a constant rate over 1 hr, every 12 hr for 21 days.

➤ *To treat herpes zoster in immunocompetent patients*

## **CAPSULES, ORAL SUSPENSION, TABLETS**

**Adults.** 800 mg every 4 hr, 5 times daily for 7 to 10 days with treatment initiated within 72 hr of onset of lesions.

➤ *To treat Varicella zoster infections in immunocompetent patients*

## **CAPSULES, ORAL SUSPENSION, TABLETS**

**Adults.** 20 mg/kg (not to exceed 800 mg) 4 times daily for 5 days initiated within 24 hr of the appearance of rash.

- *To treat Varicella zoster infections in immunocompromised patients*

## **I.V. INFUSION**

**Adults and adolescents.** 10 mg/kg infused at a constant rate over 1 hr, every 8 hr for 7 days.

**Obese adults.** 10 mg/kg (based on ideal body weight) infused at a constant rate over 1 hr, every 8 hr for 7 days.

**Children.** 20 mg/kg infused at a constant rate over 1 hr, every 8 hr for 7 days.

### ***DOSAGE ADJUSTMENT***

For patients with renal impairment who have genital herpes or *Herpes zoster* infections, oral dosage reduced or dosage interval increased as follows: if dosage is normally 200 mg every 4 hr 5 times daily and creatinine clearance is less than 10 ml/min, dosage interval increased to every 12 hr; if dosage is normally 400 mg every 12 hr and creatinine clearance is less than 10 ml/min, dosage reduced to 200 mg every 12 hr; if dosage is normally 800 mg every 4 hr and creatinine clearance is 10 to 25 ml/min, dosage interval increased to every 8 hr, and if creatinine clearance is less than 10 ml/min, dosage interval increased to every 12 hr. For patients receiving intravenous dosing, dosage reduced or dosage interval increased as follows: if creatinine clearance is 25 to 50 ml/min, dosage interval increased to every 12 hr; if creatinine clearance is 10 to 25 ml/min, dosage interval increased to every 24 hr; if creatinine clearance is 0 to 10 ml/min, dosage is reduced by 50% and dosage interval increased to every 24 hr. For patients receiving hemodialysis, an additional dose is given after each dialysis.

## **Mechanism of Action**

Several actions (inhibition of DNA polymerase, premature termination of DNA synthesis and thymidine kinase specificity) combine to inhibit herpes virus replication.

## Contraindications

Hypersensitivity to acyclovir or valacyclovir or any of their components

## Interactions

### DRUGS

*cimetidine, probenecid*: Possibly increased acyclovir plasma concentrations

*mycophenolate mofetil*: Increased plasma concentration of both drugs

## Adverse Reactions

**CNS:** Agitation, asthenia, ataxia, **coma**, confusion, dizziness, **encephalopathy**, fever, hallucinations, headache, malaise, paresthesia, psychotic symptoms, **seizures**, somnolence, tremor

**CV:** Peripheral edema

**EENT:** Visual abnormalities

**GI:** Diarrhea, elevated liver enzymes, gastrointestinal distress, **hepatitis**, hyperbilirubinemia, jaundice, nausea, vomiting

**GU:** **Acute renal failure**, elevated blood creatinine and blood urea nitrogen, hematuria, **hemolytic uremic syndrome**, renal pain

**HEME:** Anemia, leukocytosis, **leukopenia**, lymphadenopathy, **neutropenia**, **thrombocytopenia**, **thrombotic thrombocytopenic purpura**

**MS:** Myalgia

**RESP:** Dyspnea

**SKIN:** Alopecia, contact dermatitis (topical), eczema (topical), **erythema multiforme**, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, generalized pain, injection site reactions (inflammation, phlebitis)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk (not known for buccal form).
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that acyclovir therapy should be initiated as soon as possible after signs and symptoms appear.
- Use caution when administering acyclovir to patients with dehydration or preexisting renal disease or who are receiving other nephrotoxic drugs, because of increased risk of renal impairment. Also use cautiously in

patients with underlying neurologic disorders as well as electrolyte abnormalities, hepatic dysfunction, or significant hypoxia because, although uncommon, encephalopathic changes have occurred with acyclovir administration.

- Ensure that patient receiving acyclovir is adequately hydrated before drug is given, to decrease risk of renal impairment.
- Prepare intravenous infusion by first dissolving the contents of a 10-ml vial containing 500 mg of acyclovir in 10 ml of sterile water for injection. The result is a concentration of 50 mg acyclovir per each milliliter. Shake the vial well to ensure that drug has been dissolved. Use reconstituted solution within 12 hr. Know that if refrigerated, a precipitate may form but will redissolve at room temperature.
- Remove reconstituted solution from vial and add to any appropriate intravenous solution at a volume to administer over 1 hr. Once diluted for administration, each dose should be used within 24 hr.
- Administer intravenous form of acyclovir only as an infusion over 1 hr to reduce risk of renal tubular damage. Never administer it intramuscularly, subcutaneously, or as an I.V. bolus or rapid injection.

**WARNING** Know that hemolytic uremic syndrome and thrombotic thrombocytopenic purpura have occurred in immunocompromised patients receiving acyclovir therapy and have resulted in death. Report any hematologic or renal dysfunction signs and symptoms to prescriber immediately.

## **PATIENT TEACHING**

- Inform patient that acyclovir does not cure herpes infections but helps to manage the signs and symptoms.
- Tell patient prescribed buccal tablets that it is given as a single dose and should be placed onto the upper gum within 1 hr after the onset of prodromal symptoms and before the appearance of any signs of a cold sore. The tablet should not be chewed, crushed, sucked, or swallowed whole.
- Explain to patient receiving topical form of acyclovir how to apply the cream or ointment ordered, stressing need to completely cover entire lesion area and to apply only to affected areas. Tell patient to use a finger cot or rubber glove to apply to prevent transferring infection to other

parts of his body or to other people. Tell patient to start therapy as early as possible following appearance of signs and symptoms. Instruct patient not to apply topical form to the inside of his mouth or nose or to put in his eyes.

- Instruct patient prescribed oral suspension form to use an accurate measuring device when measuring dosage.
- Stress importance of stopping drug therapy and seeking immediate medical attention if any signs and symptoms of an allergic reaction occur.
- Instruct patient to seek medical attention if his symptoms become severe or he experiences troublesome adverse reactions.
- Tell women of childbearing age to notify prescriber if pregnancy occurs or is suspected.
- Stress importance of maintaining adequate hydration throughout acyclovir therapy to reduce risk of kidney damage.
- Advise patient with genital herpes to avoid contact, including intercourse, when lesions and/or symptoms are present, to avoid infecting partner.
- Instruct patient who requires acyclovir therapy to manage recurrent genital herpes to initiate therapy at the first sign or symptom of an episode.

## adalimumab

### **Humira**

## adalimumab-adbm

### **Cyltezo**

## adalimumab-adaz

### **Hyrimoz**

**adalimumab-afzb**

**Abrilada**

**adalimumab-atto**

**Amjevita**

**adalimumab-bwwd**

**Hadlima**

## **Class and Category**

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* Tumor necrosis factor (TNF) blocker

## **Indications and Dosages**

- *To reduce signs and symptoms, induce major clinical response, inhibit progression of structural damage, and improve physical function in patients with moderately to severely active rheumatoid arthritis; to reduce signs and symptoms, inhibit progression of structural damage, and improve physical function in patients with psoriatic arthritis; to reduce signs and symptoms in patients with active ankylosing spondylitis*

**SUBCUTANEOUS INJECTION (ABRILADA, AMJEVITA, CYLTEZO, HADLIMA, HUMIRA,**

## **HYRIMOZ)**

**Adults.** 40 mg every other wk.

**DOSAGE ADJUSTMENT** Dosage may be adjusted to 40 mg every wk, as needed and prescribed, for patients with rheumatoid arthritis not taking methotrexate.

- *To reduce signs and symptoms and induce and maintain clinical remission in patients with moderately to severely active Crohn's disease who have had an inadequate response to conventional therapy or who have stopped responding to or have become intolerant of infliximab*

## **SUBCUTANEOUS INJECTION (ABRILADA, AMJEVITA, CYLTEZO, HADLIMA, HUMIRA, HYRIMOZ)**

**Adults.** *Initial:* 40 mg four times daily for 1 day or 40 mg twice daily for 2 consecutive days, followed by 80 mg on day 15. *Maintenance:* 40 mg every other wk starting on day 29.

- *To reduce signs and symptoms and induce and maintain clinical remission in children with moderately to severely active Crohn's disease who have had an inadequate response to conventional therapy or who have had an inadequate response to corticosteroids or immunomodulators such as azathioprine, 6-mercaptopurine, or methotrexate*

## **SUBCUTANEOUS INJECTION (HUMIRA)**

**Children age 6 and over who weigh 40 kg (88 lb) or more.** *Initial:* 40 mg four times daily on day 1 or 40 mg twice daily for 2 days, followed by 80 mg on day 15 given in

2 divided doses of 40 mg each. *Maintenance*: 40 mg every other wk starting on day 29.

**Children age 6 and over who weigh less than 40 kg (88 lb) but at least 17 kg (37 lb).** *Initial*: 40 mg twice daily on day 1, followed by 40 mg on day 15. *Maintenance*: 20 mg every other wk starting on day 29.

- *To reduce signs and symptoms of moderately to severely active polyarticular juvenile idiopathic arthritis*

## **SUBCUTANEOUS INJECTION (HUMIRA)**

**Children age 2 and over who weigh 30 kg (66 lb) or more.** 40 mg every other wk.

**Children age 2 and over who weigh less than 30 kg (66 lb) but at least 15 kg (33 lb).** 20 mg every other wk.

**Children age 2 and over who weigh less than 15 kg (33 lb) but at least 10 kg (22 lb).** 10 mg every other wk.

## **SUBCUTANEOUS INJECTION (ABRILADA)**

**Children age 4 and over who weigh 30 kg (66 lb) or more.** 40 mg every other wk.

**Children age 4 and over who weigh less than 30 kg (66 lb) but at least 15 kg (33 lb).** 20 mg every other wk.

**Children age 4 and over who weigh less than 15 kg (33 lb) but at least 10 kg (22 lb).** 10 mg every other wk.

## **SUBCUTANEOUS INJECTION (AMJEVITA)**

**Children age 4 and over who weigh 30 kg (66 lb) or more.** 40 mg every other wk.

**Children age 4 and over who weigh less than 30 kg (66 lb) but at least 15 kg (33 lb).** 20 mg every other wk.

## **SUBCUTANEOUS INJECTION (CYLTEZO, HADLIMA, HYRIMOZ)**

**Children age 4 and over who weigh 30 kg (66 lb) or more.** 40 mg every other wk.

- *To treat moderate to severe chronic plaque psoriasis in patients who are candidates for systemic therapy or phototherapy, and when other systemic therapies are less appropriate*

## **SUBCUTANEOUS INJECTION (ABRILADA, AMJEVITA, HADLIMA, HUMIRA, HYRIMOZ)**

**Adults.** *Initial:* 80 mg followed 1 wk later with 40 mg. *Maintenance:* 40 mg every other wk.

- *To induce and sustain a remission in patients with moderate to severe active ulcerative colitis who have had an inadequate response to immunosuppressants such as azathioprine, corticosteroids, or 6-mercaptopurine*

## **SUBCUTANEOUS INJECTION (ABRILADA, AMJEVITA, CYLTEZO, HADLIMA, HUMIRA, HYRIMOZ)**

**Adults.** *Initial:* 160 mg given as four 40-mg injections on day 1 or given as two 40-mg injections on day 1 and repeated on day 2, followed by 80 mg on day 15 and 40 mg on day 29. *Maintenance:* 40 mg every other wk.

## **DOSAGE ADJUSTMENT**

Know that drug should be discontinued if there is no evidence of clinical remission by 8 weeks.

- *To treat moderate to severe hidradenitis suppurativa*

## **SUBCUTANEOUS INJECTION (HUMIRA)**

**Adults and adolescents age 12 and over weighing 60 kg (132 lb) or more.** *Initial:* 40 mg four times daily for 1 day or 40 mg twice daily for 2 consecutive days, followed by 80 mg on day 15. *Maintenance:* 40 mg weekly starting on day 29.

**Adolescents age 12 and over weighing 30 kg (66 lb) to 60 kg (132 lb).** *Initial:* 80 mg on day 1 followed by 40 mg on day 8. *Maintenance:* 40 mg every other wk starting on day 22 from initial dose.

➤ *To treat noninfectious intermediate, posterior and panuveitis*

## **SUBCUTANEOUS INJECTION (HUMIRA)**

**Adults.** *Initial:* 80 mg followed 1 wk later with 40 mg. *Maintenance:* 40 mg every other wk.

**Children age 2 and over weighing 30 kg (66 lb) or more.** 40 mg every other wk.

**Children age 2 and over weighing less than 30 kg (66 lb) but at least 15 kg (33 lb).** 20 mg every other wk.

**Children age 2 and over weighing less than 15 kg (33 lb) but at least 10 kg (22 lb).** 10 mg every other wk.

## **Mechanism of Action**

Binds to tumor necrosis factor (TNF) to block interaction with p55 and p75 cell-surface TNF receptors, and lyses surface TNF-expressing cells in the presence of complement. TNF may be a major component of rheumatoid arthritis inflammation and joint destruction. Reduced TNF level in synovial fluid improves signs and symptoms and prevents further structural damage in rheumatoid arthritis. It also causes a decrease in levels of

acute phase reactants of inflammation such as C-reactive protein, which may explain its usefulness in alleviating signs and symptoms in other inflammatory disease processes.

## Contraindications

Active infection, hypersensitivity to adalimumab or its components

## Interactions

### DRUGS

*abatacept, anakinra, rituximab*: Possibly increased risk of serious infection and neutropenia in patients with rheumatoid arthritis

*CYP450 substrates with narrow therapeutic index such as cyclosporine, theophylline, warfarin*: Possibly altered effectiveness of these drugs

*live vaccines*: Increased risk of adverse vaccine effects

## Adverse Reactions

**CNS:** Confusion, **CVA**, demyelinating disorders such as **Guillain-Barré syndrome**, or multiple sclerosis, fever, headache, **hypertensive encephalopathy**, paresthesia, **subdural hematoma**, syncope, tremor

**CV:** **Arrhythmias**, **atrial fibrillation**, **cardiac arrest**, chest pain, **congestive heart failure**, coronary artery disease, **deep vein thrombosis**, hypercholesterolemia, hyperlipidemia, hypertension, **MI**, palpitations, **pericardial effusion**, **pericarditis**, peripheral edema, **systemic vasculitis**, tachycardia

**EENT:** Cataract, optic neuritis, sinusitis

**ENDO:** **Ketosis**, parathyroid disorder

**GI:** Abdominal pain, cholecystitis, cholelithiasis, diverticulitis, elevated alkaline phosphatase level, elevated liver enzymes, esophagitis, gastroenteritis, **gastrointestinal hemorrhage, hepatic failure or necrosis, hepatitis, large bowel perforation**, nausea, **pancreatitis**, vomiting

**GU:** Hematuria, paraproteinemia, **pyelonephritis**, UTI

**HEME:** **Agranulocytosis, aplastic anemia, granulocytopenia, leukopenia**, lymphocytosis, **pancytopenia**, polycythemia, **thrombocytopenia**

**MS:** Arthritis (including pyogenic or septic arthritis); back, extremity, pelvic, or thorax pain; bone disorder, fracture, or necrosis; muscle spasms; myasthenia; prosthetic infections; synovitis

**RESP:** **Asthma**, bronchitis, **bronchospasm**, decreased pulmonary function, dyspnea, pleural effusion, pneumonia, **pulmonary embolism, pulmonary fibrosis** or tuberculosis, upper respiratory tract infection

**SKIN:** Alopecia, cellulitis, cutaneous vasculitis, erysipelas (red skin), **erythema multiforme**, herpes zoster, **lichenoid reaction, Merkel cell carcinoma**, new or worsening psoriasis, **nonmelanoma skin cancer**, rash, **Stevens-Johnson syndrome**, urticaria

**Other:** **Anaphylaxis; angioedema**; antibody formation against adalimumab; bacterial, mycobacterial, fungal, parasitic, viral, and other opportunistic infections; benign or unspecified cysts or polyps; dehydration; flare-up of disease process; flu-like symptoms; healing abnormalities; injection-site erythema, hemorrhage, itching, pain, or swelling; lupus-like symptoms; **lymphomas and other malignancies such as breast, colon, lung, melanoma,**

**and prostate**; postsurgical infection; new onset or reactivation of tuberculosis; sarcoidosis; **sepsis**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm. However, monoclonal antibodies increasingly cross the placental barrier as pregnancy progresses.
- Infants exposed to drug in utero should have risks and benefits considered before being given live or live-attenuated vaccines.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use adalimumab products cautiously in patients with recurrent infection or increased risk of infection and in patients who live in regions where tuberculosis and certain mycoses, such as *Histoplasma*, are endemic. Be aware that *Legionella* and *Listeria*, two bacterial infections, also have occurred with tumor necrosis factor-alpha blockers such as adalimumab. Monitor patient closely because infections associated with tumor necrosis factor-alpha blocker therapy may involve multiple organ systems and become life-threatening. Be aware that patients over 65 years of age, patients with other diagnoses, and patients taking concomitant immunosuppressants may be at greater risk of infection.

**WARNING** Assess patient for signs and symptoms of an active infection before beginning adalimumab therapy. If patient has evidence of an active infection when drug is

prescribed, therapy shouldn't start until the infection has been treated. Monitor all patients for infection during therapy, especially those receiving concomitant immunosuppressants. If a serious infection develops, the drug should be stopped.

- Ensure that children with juvenile idiopathic arthritis are up to date with current immunization guidelines prior to adalimumab therapy being started. However, know that they may receive vaccinations, except for live vaccines, while taking adalimumab, if needed. Be aware that the safety of administering live or live-attenuated vaccines in infants exposed to drug in utero is unknown.
- Use cautiously in a patient with a preexisting or recent onset of a central or peripheral nervous system demyelinating disorder such as multiple sclerosis, optic neuritis, or Guillain-Barré because, although rare, new onset or exacerbation of demyelinating disorders have occurred with adalimumab therapy. If this occurs, know that drug should be discontinued.
- Make sure patient has a tuberculin skin test before therapy starts. If skin test is positive, treatment of latent tuberculosis will start before adalimumab, as prescribed. Also, ensure that patient previously treated for tuberculosis, including prophylactic treatment, has a tuberculin skin test periodically throughout therapy, as adalimumab products may induce new onset or reactivate tuberculosis. Also monitor patient for signs and symptoms of tuberculosis as tests for latent tuberculosis infection may be falsely negative while taking adalimumab.
- Review patient's medical and medication history and discuss with prescriber prior to starting an adalimumab product.
- Be aware that the needle cover of the syringe contains dry rubber. Don't handle if allergic to latex.
- Know that adalimumab products must be refrigerated but may be left at room temperature with cap or cover on for about 15 to 30 minutes before injecting. Inject daily doses in separate sites in the abdomen or thigh. Rotate injection sites and do not give injections into an area where the skin is bruised, hard, red, or tender.
- Activate the protection device on needles of prefilled syringes delivered to institutions by holding the syringe in one hand and, with the other hand, sliding outer protective shield over exposed needle until it locks into place.

- Know that adalimumab may come in a single-use glass vial containing 40 mg (0.8 ml) of adalimumab referred to as an “institutional use vial” because the drug should only be given in a medical institution. Withdraw only one dose when using the “institutional use vial” and administer promptly. Since the vial does not contain preservatives, discard any unused portions.

**WARNING** Stop adalimumab immediately and tell prescriber if patient has an allergic reaction. Expect to provide supportive care.

- Watch closely for evidence of congestive heart failure (sudden, unexplained weight gain; dyspnea; crackles; anxiety), and notify prescriber if they occur.
- Monitor patient’s CBC, as ordered, because adalimumab products may have adverse hematologic effects. Notify prescriber about persistent bleeding, bruising, fever, or pallor.
- Be aware that, although rare, malignancies, especially lymphomas and leukemias, have occurred in patients receiving TNF blockers such as adalimumab products. These malignancies have also occurred in children. Patients with rheumatoid arthritis, especially those with very active disease, and patients with ankylosing spondylitis, Crohn’s disease, plaque psoriasis, or psoriatic arthritis are at greatest risk. Monitor patients closely.

## **PATIENT TEACHING**

- Inform patient that the first injection of adalimumab must take place with a healthcare professional present.
- Teach patient or caregiver how to give adalimumab as a subcutaneous injection at home, if applicable. Emphasize importance of injecting the full amount in the syringe to obtain the correct dose.
- Advise patient that the needle cover contains rubber and can cause a latex-induced allergic reaction if touched with bare hands.
- Provide patient or caregiver with a puncture-resistant container for disposal of needles and syringes at home.
- Instruct patient or caregiver to rotate injection sites in the abdomen and thigh and to avoid injecting in any area that’s bruised, hard, red, or tender.

- Inform patient that prefilled syringes must be refrigerated (not frozen) but may be left at room temperature for 15 to 30 minutes before injecting to decrease injection discomfort. Keep the cap or cover on while allowing it to reach room temperature. Also keep syringe protected from light and stored in the original container.
- Urge patient to check expiration dates and not to use outdated drug. Also tell patient not to use a prefilled syringe if the liquid is cloudy, discolored, or has flakes or particles in it.
- Review signs and symptoms of an allergic reaction (difficulty breathing, rash, swollen face), and tell patient to seek emergency care immediately if these occur.
- Inform patient that injection-site reactions (such as bruising itching, rash, redness, and swelling) may occur but are usually mild and transient. Instruct him to apply a towel soaked with cold water on the injection site if it hurts or remains swollen. If reaction does not disappear or seems to worsen, tell patient to call prescriber immediately.
- Inform patient that tuberculosis may occur during adalimumab therapy. Instruct him to report persistent cough, wasting or weight loss, and low-grade fever to prescriber.
- Teach patient how to recognize evidence of infection and bleeding disorders and to tell prescriber if they occur; drug may need to be stopped. Advise patient to avoid people with infections and to have all prescribed laboratory tests.
- Inform patient that the risk of certain kinds of cancer, especially lymphomas, is higher in patients taking adalimumab but still rare. Emphasize the importance of follow-up visits and reporting an unusual or sudden onset of signs or symptoms.
- Caution patient against receiving live-virus vaccines while taking adalimumab because doing so may adversely affect the immune system.
- Inform patient that blood samples may be needed periodically, but especially around week 24 of therapy, to check for autoantibody development. Explain that adalimumab therapy will have to be stopped if it's detected.
- Instruct patient to report lupus-like signs and symptoms that, although rare, may occur during therapy, such as chest pain that doesn't go away, joint pain, a rash on arms or cheeks that is sensitive to the sun, or shortness of breath. Explain that drug may be stopped if these occur.
- Advise patient to inform all healthcare providers about adalimumab use and to inform prescriber about any OTC medications being taken, including herbal remedies and mineral and vitamin supplements.

- Instruct women of childbearing age to notify prescriber immediately if pregnancy is suspected or known, as adalimumab products may affect the immune response of an utero-exposed newborn or infant. Also, emphasize the importance of telling pediatrician if an adalimumab product was taken any time during pregnancy, prior to having infant receive any vaccines.
- Encourage mother wishing to breastfeed infant to discuss with prescriber before doing so.

## adefovir dipivoxil

### Hepsera

## Class and Category

*Pharmacologic class:* Nucleotide analogue

*Therapeutic class:* Antiviral

## Indications and Dosages

- *To treat chronic hepatitis B in patients with evidence of active viral replication and either evidence of persistent elevations in serum aminotransferases (ALT or AST) or histologically active disease*

### **TABLETS**

**Adults and children age 12 and over.** 10 mg once daily.

***DOSAGE ADJUSTMENT*** For patients with a creatinine clearance between 30 and 49 ml/min, dosage interval changed to every 48 hr. For patients with a creatinine clearance between 10 and 29 ml/min, dosage interval changed to 72

hr. For patients receiving hemodialysis, dosage interval changed to every 7 days following dialysis.

## Mechanism of Action

Inhibits hepatitis B virus (HBV) by competing with the natural substrate deoxyadenosine triphosphate and by causing DNA chain termination after its incorporation into viral DNA, which prevents replication.

## Contraindications

Hypersensitivity to adefovir dipivoxil or its components

## Interactions

### DRUGS

*drugs that are excreted renally or known to affect renal function, such as aminoglycosides, cyclosporine, NSAIDs, tacrolimus, and vancomycin:* Possibly increased serum concentrations of adefovir or these drugs or both, increasing risk of adverse reactions

## Adverse Reactions

**CNS:** Asthenia, headache

**GI:** Abdominal pain, diarrhea, dyspepsia, flatulence, nausea, **pancreatitis, severe acute exacerbations of hepatitis, severe hepatomegaly with steatosis**, vomiting

**GU:** Abnormal renal function, elevated creatinine level, **Fanconi syndrome, nephrotoxicity, proximal renal tubulopathy, renal failure**

**MS:** Bone pain, myopathy, osteomalacia

**SKIN:** Pruritus, rash

**Other:** **HIV resistance**, hypophosphatemia, **lactic acidosis**

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Check to be sure HIV antibody testing has been done prior to starting adefovir therapy because treatment with anti-hepatitis B therapies, such as adefovir, may cause an emergence of HIV resistance.
- Use with extreme caution in patients with renal dysfunction. Check to ensure that patient's creatinine clearance is known before adefovir therapy begins and then rechecked periodically throughout therapy, because adefovir may cause a delayed nephrotoxicity that may require dosage interval to be lengthened or drug discontinued. Know that patients at higher risk include those having underlying renal dysfunction and patients taking concomitant nephrotoxic agents such as aminoglycosides, cyclosporine, NSAIDs, tacrolimus, and vancomycin.
- Use caution when administering adefovir to patient with liver dysfunction or known risk factors for liver disease.

**WARNING** Know that lactic acidosis and severe hepatomegaly with steatosis have occurred with adefovir therapy and death has occurred in some patients. Risk factors include presence of obesity, prolonged nucleoside exposure, and being a woman. However, know that lactic acidosis and severe hepatomegaly with steatosis have also occurred in patients with no known risk factors. Expect drug to be discontinued in any patient who develops clinical or laboratory findings suggestive of lactic acidosis or pronounced hepatotoxicity, even in the absence of marked transaminase elevations.

- Monitor patient throughout treatment for evidence of loss of therapeutic response. Indicators include increasing levels of HBV DNA over time after an initial decline below assay limit, progression of clinical signs or symptoms of hepatic disease and/or worsening of hepatic necroinflammatory findings, or return of persistently elevated ALT levels. These findings may require drug to be discontinued.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including adefovir. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus infection, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.
- Expect patient to be closely monitored for at least several months after adefovir has been discontinued, because exacerbation of hepatitis may occur, some cases of which have been severe.

## **PATIENT TEACHING**

- Instruct patient to take adefovir once daily. If he misses a dose, tell him to take it as soon as he remembers but not to double the next dose or take more than the prescribed dose.
- Advise patient that treatment with adefovir does not reduce the risk of transmission of HBV to others.

- Tell patient to report any new or worsening symptoms to prescriber immediately, because emergence of resistant hepatitis B virus may occur or disease may worsen during treatment.
- Instruct patient with hepatitis B on the importance of testing for HIV before therapy begins and then periodically throughout therapy to avoid development of resistance to HIV treatment.
- Warn patient with hepatitis B that acute severe exacerbations of hepatitis B may occur following discontinuation of adefovir. He should not discontinue drug without prescriber knowledge. Tell patient to report any reappearance of signs and symptoms of hepatitis B.
- Instruct mother not to breastfeed while she is receiving adefovir therapy, as drug is present in human milk.
- Tell women of childbearing age to report a known or suspected pregnancy.

**WARNING** Alert patient that severe conditions may develop while taking adefovir. Encourage him to stop taking drug and seek medical attention immediately if he experiences any persistent, severe, or unusual symptoms; especially abdominal pain, change in urine characteristics or urination pattern, loss of appetite, pale stools, muscle pain, or yellowing of the eyes.

## adenosine

**Adenocard, Adenoscan**

### Class and Category

*Pharmacologic class:* Nucleoside

*Therapeutic class:* Class V antiarrhythmic, diagnostic aid

## Indications and Dosages

- *To convert paroxysmal supraventricular tachycardia (PSVT) to normal sinus rhythm*

### I.V. INJECTION (ADENOCARD)

**Adults and children weighing 50 kg (110 lb) or more.**

*Initial:* 6 mg by rapid peripheral I.V. bolus over 1 to 2 sec. If PSVT continues after 1 to 2 min, 12 mg given as rapid bolus and repeated in 1 to 2 min, if needed. *Maximum:* 12 mg as a single dose.

**Children weighing less than 50 kg.** *Initial:* 0.05 to 0.1 mg/kg by rapid central or peripheral I.V. bolus followed by a saline flush. If PSVT continues after 1 to 2 min, additional bolus injections are given, incrementally increasing dose by 0.05 to 0.1 mg/kg. Each bolus followed with a saline flush. Administration continued until PSVT converts to normal sinus rhythm or until patient reaches maximum single dose. *Maximum:* 0.3 mg/kg as a single dose.

- *Adjunct to thallium-201 myocardial perfusion scintigraphy in patients unable to exercise adequately during testing*

### I.V. INJECTION (ADENOSCAN)

**Adults.** 140 mcg/kg/min infused over 6 minutes continuously (total infused dose of 0.84 mg/kg).

Route	Onset	Peak	Duration
I.V.	Immediate	Immediate	Unknown

## Mechanism of Action

Slows conduction time through the AV node and can interrupt AV node reentry pathways to restore normal sinus rhythm.

## Incompatibilities

Don't mix adenosine with other drugs.

## Contraindications

Hypersensitivity to adenosine or its components; second- or third-degree heart block or sick sinus syndrome, except in patients with a functioning artificial pacemaker

## Interactions

### DRUGS

*carbamazepine*: Increased degree of heart block

*digoxin, verapamil*: Possibly increased depressant effect on SA or AV node and increased risk of ventricular fibrillation

*dipyridamole*: Increased adenosine effects

*methyloxanthines, such as theophylline*: Antagonized adenosine effects

### FOODS

*caffeine*: Antagonized adenosine effects

## Adverse Reactions

**CNS**: Apprehension, **CVA**, dizziness, headache, heaviness in arms, light-headedness, nervousness, paresthesia, **seizures**

**CV:** Atrial fibrillation, bradycardia, cardiac arrest, chest pain or pressure, heart block, hypertension, hypotension, MI, palpitations, prolonged asystole, tachycardia, sinus exit block or pause, sustained ventricular tachycardia, torsades de pointes, transient hypertension, ventricular fibrillation

**EENT:** Blurred vision, metallic taste, throat tightness

**GI:** Nausea, vomiting

**MS:** Jaw, neck, and back pain

**RESP:** Bronchoconstriction, bronchospasm, dyspnea, hyperventilation, respiratory arrest

**SKIN:** Diaphoresis, erythema, facial flushing, rash

**Other:** Injection-site reactions including pain, sensitivity reactions

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Know that Adenoscan should not be given to patients with signs and symptoms of acute myocardial ischemia, as these patients may be at greater risk for serious cardiovascular reactions, including a myocardial infarction during a medical stress test.
- Inspect adenosine for crystals before use. If solution isn't clear, don't give it.
- Give Adenocard used to convert PSVT to normal sinus rhythm by rapid I.V. bolus over 1 to 2 seconds. Slower delivery can cause systemic vasodilation and reflex tachycardia. Give Adenoscan used as an adjunct to thallium-201 myocardial perfusion scintigraphy as a continuous peripheral intravenous infusion over 6 minutes. Know that the required dose of thallium-201 should be injected at the midpoint of the Adenoscan infusion. It is compatible with Adenoscan and may be injected directly into the Adenoscan infusion set.
- Expect prescriber to inject adenosine directly into a vein to make sure drug reaches systemic circulation. If given into an I.V. line, give drug as close to insertion site as possible and follow with rapid saline flush.

**WARNING** Don't give single doses of Adenocard more than 12 mg.

- Monitor heart rate and rhythm, blood pressure, and respiratory status often during adenosine therapy.
- Be aware that at the time of conversion to normal sinus rhythm, arrhythmias (such as premature atrial or ventricular contractions, sinus bradycardia, sinus tachycardia, or AV block) may occur for a few seconds, but they don't usually require intervention.

**WARNING** Stop drug use and notify prescriber immediately if severe respiratory difficulties develop *or patient develops other signs of hypersensitivity such as chest discomfort, erythema, flushing, or rash.*

- Store adenosine at room temperature. Discard unused portion.

## PATIENT TEACHING

- Inform patient of increased risk for serious adverse effects. Instruct patient to report chest pain, palpitations, difficulty breathing, or severe

headache during adenosine therapy.

- Warn patient that mild, temporary reactions may occur, such as flushing, nausea, and dizziness.

## albuterol sulfate (salbutamol sulphate)

**AccuNeb, ProAir Digihaler, Proair HFA, ProAir Respiclick, Ventolin HFA, VoSpire ER**

### Class and Category

*Pharmacologic class:* Adrenergic

*Therapeutic class:* Bronchodilator

### Indications and Dosages

- *To prevent exercise-induced bronchospasm*

#### INHALATION POWDER

**Adults and children age 4 and over.** Two inhalations 15 to 30 min before exercise.

- *To treat bronchospasm in patients with reversible obstructive airway disease*

#### E.R. TABLETS

**Adults and children over age 12.** *Initial:* 4 or 8 mg every 12 hr. *Maximum:* 32 mg daily in divided doses every 12 hr.

**Children ages 6 to 12.** *Initial:* 4 mg every 12 hr.  
*Maximum:* 24 mg daily in divided doses every 12 hr.

## SYRUP

**Adults and children over age 14.** *Initial:* 2 to 4 mg (1 to 2 tsp) three or four times daily. *Maximum:* 32 mg daily in divided doses.

**Children ages 6 to 14.** *Initial:* 2 mg (1 tsp) three or four times daily. *Maximum:* 24 mg daily in divided doses.

**Children ages 2 to 6.** *Initial:* 0.1 mg/kg three times daily (not to exceed 2 mg three times daily), increased to 0.2 mg/kg three times daily (not to exceed 4 mg three times daily). *Maximum:* 12 mg daily in divided doses.

## TABLETS

**Adults and children over age 12.** *Initial:* 2 or 4 mg three or four times daily. *Maximum:* 32 mg daily in divided doses.

**Children ages 6 to 12.** *Initial:* 2 mg three or four times daily. *Maximum:* 24 mg daily in divided doses.

**DOSAGE ADJUSTMENT** For elderly patients and patients sensitive to beta-adrenergic stimulation, initial dosage reduced to 2 mg (1 tsp) of syrup three or four times daily or 2 mg of tablets three or four times daily (up to 32 mg daily).

## Mechanism of Action

Albuterol attaches to  $\beta_2$  receptors on bronchial cell membranes, which stimulates the intracellular enzyme adenylate cyclase to convert adenosine triphosphate (ATP) to cyclic adenosine monophosphate (cAMP). This reaction decreases intracellular calcium levels. It also increases intracellular levels of cAMP, as shown.

Together, these effects relax bronchial smooth-muscle cells and inhibit histamine release.

## INHALATION SOLUTION

**Adults and children age 12 and over.**

2.5 mg three or four times daily, as needed, by nebulization over 5 to 15 min.

**Children ages 2 to 12. Initial:** 0.63 mg or 1.25 mg three or four times daily, as needed, by nebulization over 5 to 15 min.

➤ *To treat or prevent brochospasms in*

## INHALATION POWDER

**Adults and children age 4 and over.** 1 inhalation every 4 hr to 2 inhalations every 4 to 6 hr.

## INHALATION POWDER (PROAIR RESPICLICK)

**Adults and children 4 yr and over.** 1 inhalation every 4 hr or 2 inhalations every 4 to 6 hr.

Route	Onset	Peak	Duration
P.O. (E.R. tab)	30 min	2-3 hr	12 hr
P.O. (syrup)	Rapid	2 hr	Unknown
P.O. (tab)	30 min	2-3 hr	4-8 hr
Inhalation (powder)	5-15 min	50-55 min	3-6 hr
Inhalation (solution)	5-15 min	1-2 hr	3-6 hr

## Contraindications

Hypersensitivity to albuterol or its components

## Interactions

### DRUGS

*beta blockers:* Inhibited effects of albuterol

*bronchodilators (sympathomimetics), such as theophylline:*

Possibly adverse CV effects

*digoxin:* Decreased serum digoxin level

*MAO inhibitors, tricyclic antidepressants:* Increased vascular effects of albuterol

*potassium-lowering drugs:* Possibly hypokalemia

*potassium-wasting diuretics:* Possibly increased hypokalemia

# Adverse Reactions

**CNS:** Anxiety, dizziness, drowsiness, headache, hyperkinesia, insomnia, irritability, nervousness, tremor, vertigo, weakness

**CV:** **Angina**, **arrhythmias**, chest pain, hypertension, **hypotension**, palpitations

**EENT:** Altered taste, dry mouth and throat, ear pain, glossitis, hoarseness, **oropharyngeal edema**, pharyngitis, rhinitis, taste perversion

**ENDO:** Hyperglycemia

**GI:** Anorexia, diarrhea, dysphagia, heartburn, nausea, vomiting

**GU:** UTI

**MS:** Muscle cramps

**RESP:** **Bronchospasm**, cough, dyspnea, **paradoxical bronchospasm**, **pulmonary edema**

**SKIN:** Diaphoresis, flushing, pallor, pruritus, rash, urticaria

**Other:** **Angioedema**, **hypokalemia**, infection, **metabolic acidosis**

# Childbearing Considerations

## PREGNANCY

- Pregnancy exposure registry: 1-877-311-8972 or <http://mothertobaby.org/pregnancystudies/>.
- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LABOR & DELIVERY

- Drug should only be used if benefit to mother during labor clearly outweighs the risk for beta-agonist interference with uterine contractility.
- Drug should not be used for management of preterm labor because serious adverse reactions, including pulmonary edema, have been reported in the mother.

## LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Administer pressurized inhalations of albuterol during second half of inspiration, when airways are open wider and aerosol distribution is more effective.

**WARNING** Use cautiously in patients with cardiac disorders, diabetes mellitus, digitalis intoxication, hypertension, hyperthyroidism, or history of seizures. Albuterol can worsen these conditions.

- Monitor serum potassium level because albuterol may cause transient hypokalemia.
- Be aware that drug tolerance can develop with prolonged use.

## PATIENT TEACHING

- Teach patient how to use inhaler. Tell him if he is prescribed Proair HFA to shake canister before use and to check that a new canister is working by spraying it the appropriate number of times (once to four times based on manufacturer instructions) into the air while looking for a fine mist. However, if patient is prescribed the ProAir Digihaler or ProAir Respiclick

device, tell him that they do not require priming and these devices should not be used with a spacer or volume holding chamber.

- Instruct patient to wash mouthpiece with water once a week and let it air-dry if patient is using a Proair HFA device. However, if patient is using a ProAir Digihaler or ProAir RespiClick device, he should not wash or put these devices in water. Instead they should be cleaned by gently wiping the mouthpiece with a dry cloth or tissue, if needed. Tell patient to discard the ProAir Digihaler and ProAir RespiClick devices after 13 months from opening the foil pouch or after the expiration date, whichever comes first. The ProAir RespiClick device should also be discarded before 13 months from opening the foil pouch if the dose counter displays 0.
- Advise patient to wait at least 1 minute between inhalations if dosage requires more than one inhalation.
- Tell patient to check with his prescriber before using other inhaled drugs.
- Warn patient not to exceed prescribed dose or frequency. If doses become less effective, tell patient to contact his prescriber.
- Tell patient to immediately report signs and symptoms of allergic reaction, such as difficulty swallowing, itching, and rash.

## alemtuzumab

### Lemtrada

## Class and Category

*Pharmacologic class: Monoclonal antibody*

*Therapeutic class: Immunomodulator*

## Indications and Dosages

- *To treat relapsing forms of multiple sclerosis and to include relapsing-remitting disease and active secondary progressive disease in patients who have*

*had an inadequate response to two or more drugs indicated for the treatment of multiple sclerosis*

## **I.V. INFUSION**

**Adults.** *First treatment course:* 12 mg/day infused over 4 hr on 5 consecutive days for 60 mg total dose. *Second treatment course:* 12 mg/day infused over 4 hr on 3 consecutive days for 36 mg total dose administered 12 months after first treatment course. *Subsequent treatment courses:* 12 mg/day infused over 4 hr on 3 consecutive days for 36 mg total dose administered 12 months after last dose of any prior treatment course.

## **Mechanism of Action**

Possibly binds to CD52, a cell surface antigen present on T and B lymphocytes and on natural killer cells, macrophages, and monocytes. This results in antibody-dependent cellular cytotoxicity and complement-mediated lysis.

## **Contraindications**

Hypersensitivity to alemtuzumab or its components, presence of HIV infection

## **Interactions**

### **DRUGS**

*antineoplastics, immunosuppressants:* Increased risk of immunosuppression

*live viral vaccines:* Increased risk of infection

*myelosuppressive agents*: Enhanced myelosuppressive effects

## Adverse Reactions

**CNS:** Anxiety, asthenia, chills, **CVA**, dizziness, fatigue, fever, **Guillain-Barré syndrome**, headache, insomnia, paresthesia, **progressive multifocal leukoencephalopathy**, **suicidal ideation**

**CV:** **Cervicocephalic arterial dissection**, **myocardial ischemia**, peripheral edema, tachycardia, vasculitis

**EENT:** Epistaxis, nasopharyngitis, oropharyngeal pain, sinusitis, taste distortion

**ENDO:** Thyroid dysfunction

**GI:** Abdominal pain, **autoimmune hepatitis**, cholecystitis, diarrhea, dyspepsia, nausea, vomiting

**GU:** Abnormal uterine bleeding, **antiglomerular basement membrane disease**, hematuria, membranous glomerulonephritis, UTI

**HEME:** **Decreased CD4 and CD8 lymphocytes and T-lymphocyte count**, **hemolytic anemia**, **hemophagocytic lymphohistiocytosis**, **immune thrombocytopenia**, **lymphopenia**, **neutropenia**, **pancytopenia**

**MS:** Arthralgia; back, extremity, or neck pain; muscle weakness; myalgia

**RESP:** Cough, dyspnea, **hypersensitivity pneumonitis**, **pneumonitis with fibrosis**, **pulmonary alveolar hemorrhage**, upper respiratory infection

**SKIN:** Dermatitis, erythema, flushing, pruritus, rash, urticaria

**Other:** Alemtuzumab antibodies; **anaphylaxis**; autoimmune conditions; **bacterial**, **fungal**, **herpes**, **opportunistic**, **or other viral infections** (serious to **life-**

**threatening**); flu-like symptoms; **infusion reactions** (serious to **life-threatening**); **malignancies**

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-758-2990.
- Drug may cause fetal harm, as placental transfer of antithyroid antibodies to fetus may result in neonatal Graves' disease.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### REPRODUCTION

- Women of childbearing age should use effective contraceptive measures during drug therapy and for 4 months following that course of treatment.
- Animal studies have shown adverse effects on sperm parameters in males and reduced number of corpora lutea and implantations in females.

## Nursing Considerations

- Know that alemtuzumab is only available through a restricted distribution under a Risk Evaluation Mitigation Strategy Program because of the risk of autoimmunity, infusion reactions, and malignancies.
- Expect baseline laboratory tests to be performed prior to alemtuzumab therapy and periodically thereafter as follows: Complete blood count (CBC) with differential prior to and then monthly; serum creatinine levels prior to and then monthly; thyroid function test, such as a thyroid-stimulating hormone level, prior to and then every 3 months; and urinalysis with urine cell counts, including urine protein to creatinine ratio, prior to and then monthly. Also expect to check serum transaminase and total bilirubin levels prior to and then periodically and to perform a

baseline skin examination followed by yearly exams for melanoma. Expect to continue monitoring these test results for up to 48 months after last dose is infused.

- Complete any necessary immunizations at least 6 weeks prior to treatment, as prescribed. Determine if patient has a history of varicella or has been vaccinated for varicella zoster virus. If not, expect patient to be tested for antibodies to varicella zoster virus and vaccination to occur in patients who are antibody-negative. Expect alemtuzumab treatment to be postponed until 6 weeks after vaccination. Also, ensure that tuberculosis screening has been done prior to drug therapy and treatment started, if needed, prior to alemtuzumab therapy.

**WARNING** Assess patient for signs and symptoms of an infection prior to beginning therapy and then before each infusion because infections frequently occur with alemtuzumab treatment and can become life-threatening. Examples of infections that may occur include serious infections such as appendicitis, gastroenteritis, pneumonia, and tooth infections; fungal infections; herpes viral infections; human papilloma virus infections; *Listeria monocytogenes* infections; opportunistic infections; and tuberculosis. Know that treatment may be delayed until active infection is under control.

**WARNING** Screen patients at high risk of hepatitis B virus or hepatitis C virus, as ordered, before alemtuzumab is initiated, because patient may be at risk of irreversible liver damage caused by a potential virus reactivation.

- Be prepared to premedicate patient with high-dose corticosteroids such as 1,000 mg of methylprednisolone or equivalent, as prescribed, immediately prior to alemtuzumab infusion and for first 3 days of each treatment course to decrease risk of infusion reactions. Also know that antihistamines and/or antipyretics may be prescribed to be given prior to infusion. Be aware that despite these measures, a serious infusion reaction may still occur. Immediate discontinuation should be considered if a serious infusion reaction occurs.
- Expect to administer antiviral prophylaxis for herpetic viral infections, as prescribed, starting on the first day of each treatment course and continuing for a minimum of 2 months following treatment or until CD4+

lymphocyte count is at least 200 cells per microliter, whichever occurs later.

- Prepare alemtuzumab for administration by inspecting vial for particulate matter and discoloration. Do not freeze or shake vials prior to use. Withdraw 1.2 ml from drug vial into a syringe and inject into a 100-ml bag of sterile 0.9% sodium chloride, USP or 5% dextrose in water, USP. Gently invert bag to mix solution. Ensure the sterility of the prepared solution because it contains no antimicrobial preservatives. Also protect it from light. Diluted solution may be stored for up to 8 hours refrigerated or at room temperature.
- Monitor vital signs before infusion and periodically during infusion. Infuse alemtuzumab over 4 hours starting within 8 hours after dilution. Know that duration of infusion may be extended if clinically indicated. Do not add or simultaneously infuse other drug substances through the same intravenous line. Do not give drug as a bolus or I.V. push.

**WARNING** Be aware that alemtuzumab may cause serious and life-threatening infusion reactions. These may include anaphylaxis, angioedema, bradycardia, bronchospasm, chest pain, fever, headache, hypertension or hypotension, rash, tachycardia (including atrial fibrillation), or transient neurologic symptoms. Other infusion adverse reactions may include chills, dizziness, dyspepsia, dyspnea, fatigue, insomnia, nausea, pain, pruritus, pulmonary infiltrates, and urticaria. Observe patient during and for at least 2 hours after each infusion. Question patient frequently regarding symptoms they may be experiencing. Be prepared to manage anaphylaxis or serious infusion reactions immediately, if present.

**WARNING** Monitor patient for signs and symptoms of progressive multifocal leukoencephalopathy (PML). If any occur, notify prescriber immediately and withhold drug while diagnostic evaluation is ongoing. If confirmed, provide appropriate and supportive care, as prescribed.

**WARNING** Know that alemtuzumab causes serious, sometimes fatal, autoimmune conditions such as

antiglomerular basement membrane disease and immune thrombocytopenia. Expect to monitor CBC with differential, serum creatinine levels, and urinalysis with urine cell counts at periodic intervals for 48 months after last dose.

- Monitor patient's cardiovascular and pulmonary systems for adverse reactions, such as cervicocephalic arterial dissection involving multiple arteries and stroke that may occur within 3 days of infusion, with most occurring within 1 day.
- Monitor patient's renal function, as ordered. Notify prescriber immediately of any abnormalities, including hemoptysis (a common lung component), because urgent evaluation and treatment can improve the preservation of renal function. Know that glomerular nephropathies can occur up to 40 months after the last dose of alemtuzumab. Expect patient's urine protein-to-creatinine ratio to be measured if urine dipstick shows 1+ protein or greater.
- Monitor patient for liver dysfunction, because drug can cause significant liver injury.
- Patients should also be monitored for Grave's disease (hyperthyroidism-palpitations, tachycardia, heat intolerance, frequent bowel movements, eye lid retraction/lag, irritability).
- Be aware that alemtuzumab may cause an increased risk of malignancies, including lymphoproliferative disorders, melanoma, and thyroid cancer. Expect baseline exam and yearly follow-ups to be done.
- Be aware that alemtuzumab contains the same active ingredient found in another drug called Campath. If patient has been previously treated with Campath, monitor patient for additive and long-lasting effects on the immune system.

## **PATIENT TEACHING**

**WARNING** Inform patient that alemtuzumab may cause serious to life-threatening infusion reactions. Patient should seek immediate medical attention if a reaction occurs, because reactions can occur for up to 48 hours after infusion.

**WARNING** Review signs of a stroke with patient. Instruct patient to seek immediate medical attention if

symptoms of stroke occur. Also instruct patient to report any signs and symptoms of infection, as well as other signs and symptoms that are not common to patient, such as chest pain or tightness, cough, hemoptysis, shortness of breath, or wheezing.

- Instruct patients to avoid potential sources of *Listeria monocytogenes*, such as deli meat, dairy products made with unpasteurized milk, poultry, seafood, soft cheeses, or undercooked meat. Review signs and symptoms for *Listeria* infection because the duration of increased risk is unknown. Some cases have been reported up to 8 months after last dose.
- Stress importance of having a yearly skin exam.
- Encourage female patients to have an annual human papilloma virus screening done.

## alendronate sodium

**Binosto, Fosamax**

### Class and Category

*Pharmacologic class:* Bisphosphonate

*Therapeutic class:* Bone resorption inhibitor

### Indications and Dosages

➤ *To prevent postmenopausal osteoporosis*

#### **TABLETS**

**Adults.** 5 mg daily or 35 mg once/wk in the morning with a full glass of water at least 30 min before first food, drink, or

other drugs.

- *To treat postmenopausal osteoporosis*

## **ORAL SOLUTION, TABLETS**

**Adults.** 10 mg (tablet) daily or 70 mg (oral solution or tablet) once/wk in the morning with a full glass of water at least 30 min before first food, drink, or other drugs.

## **EFFERVESCENT TABLETS**

**Adults.** 70 mg once/wk in the morning dissolved in 4 ounces of room-temperature water at least 30 min before first food, drink, or other drugs.

- *To treat Paget's disease of the bone in patients whose alkaline phosphatase level is twice the upper limit of symptomatic and at risk for further complications*

## **TABLETS**

**Adults.** 40 mg daily with a full glass of water for 6 months. Treatment repeated following a 6 month posttreatment evaluation period, if needed, in patients who have failed to normalize their serum alkaline phosphatase levels or have relapsed based on increases in alkaline phosphatase.

- *To increase bone mass in men with osteoporosis*

## **ORAL SOLUTION, TABLETS**

**Adults.** 10 mg (tablet) daily or 70 mg (oral solution or tablet) once/wk in the morning with a full glass of water at least 30 min before first food, drink, or other drugs.

## **EFFERVESCENT TABLETS**

**Adults.** 70 mg once/wk in the morning dissolved in 4 ounces of room temperature water at least 30 min before

first food, drink, or other drugs.

- *To treat glucocorticoid-induced osteoporosis in men and women who receive a daily glucocorticoid dosage of 7.5 mg or greater of prednisone and who have low bone-mineral density*

## TABLETS

**Adults.** 5 mg daily in the morning with a full glass of water at least 30 min before first food, drink, or other drugs.

**DOSAGE ADJUSTMENT** Dosage for glucocorticoid-induced osteoporosis increased to 10 mg daily for postmenopausal women not receiving estrogen.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	6 wk*

\* After single 5-mg dose for osteoporosis; 6 months after single 5-mg dose for Paget's disease.

## Mechanism of Action

Reduces activity of cells that cause bone loss, slows rate of bone loss after menopause, and increases amount of bone mass. May act by inhibiting osteoclast activity on newly formed bone resorption surfaces, which reduces the number of sites where bone is remodeled. Bone formation then exceeds bone resorption at these remodeling sites, which gradually increases bone mass. May also inhibit bone dissolution by binding to hydroxyapatite crystals, which are composed of calcium, phosphate, and hydroxide and give bone its rigid structure.

## Contraindications

Esophageal abnormalities that delay esophageal emptying, such as achalasia or stricture; hypersensitivity to alendronate or its components; hypocalcemia; inability to stand or sit upright for at least 30 minutes

## Interactions

### DRUGS

*antacids, calcium, iron, multivalent cations:* Decreased absorption of alendronate

*aspirin:* Increased risk of GI distress

*levothyroxine:* Possibly slight decrease in bioavailability of alendronate

### FOODS

*any food:* Delayed absorption and decreased serum level of alendronate

## Adverse Reactions

**CNS:** Asthenia, dizziness, headache, vertigo

**CV:** Peripheral edema

**EENT:** Cholesteatoma of external auditory canal

**GI:** Abdominal distention and pain, constipation, diarrhea, dysphagia, **esophageal perforation** or ulceration, esophagitis, flatulence, gastritis, gastroesophageal reflux disease, heartburn, indigestion, **melena**, nausea, vomiting

**MS:** Arthralgia; femoral shaft or subtrochanteric fractures; focal osteomalacia; jaw osteonecrosis; joint swelling; muscle spasms; myalgia; severe bone, joint, and/or muscle pain

**RESP:** Asthma exacerbation

**SKIN:** Photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

**Other:** Anaphylaxis, hypocalcemia

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug should be discontinued as soon as pregnancy is known.
- Know that there is a theoretical risk of fetal harm, especially skeletal, if a woman becomes pregnant after completing a course of biphosphonate therapy. Time between cessation of drug therapy to conception, the particular bisphosphonate used, and route of administration causing fetal harm is unknown.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that alendronate should not be administered to patients who have esophageal disorders, hypocalcemia, or are unable to sit upright or stand for at least 30 minutes.
- Prepare to administer effervescent form of alendronate by dissolving one tablet in 4 ounces of plain water (do not use mineral water or flavored water) that is at room temperature. Wait 5 minutes after effervescence stops and then stir the solution for about 10 seconds before handing to patient to ingest.
- Monitor patient's serum calcium level before, during, and after treatment. Expect hypocalcemia to be treated before alendronate therapy begins. If

hypocalcemia occurs during therapy, expect prescriber to order a calcium supplement.

- Ensure adequate dietary intake of calcium and vitamin D before, during, and after treatment.
- Be aware that oral osteoporosis drugs such as alendronate may have the potential to increase the risk of esophageal cancer. While studies are underway to determine this potential, assess patient regularly for painful or difficulty swallowing, chest pain, or new or worsening heartburn; notify prescriber if present.

**WARNING** Monitor patient closely, as alendronate may irritate upper GI mucosa, causing adverse reactions such as esophageal ulceration. To help minimize these reactions, have patient take drug with a full glass of water and remain upright for at least 30 minutes.

- Monitor patient for jaw pain because alendronate may cause osteonecrosis of the jaw, with risk increasing as therapy duration becomes longer. Patients at increased risk include those who have poor oral hygiene, preexisting dental or periodontal disease, wear ill-fitting dentures, or require an invasive dental procedure. Patients are also at increased risk if they have a cancer diagnosis, concomitant therapy such as chemotherapy or corticosteroid therapy, or other illnesses, such as preexisting dental or periodontal disease, anemia, coagulopathy, or infection.

## PATIENT TEACHING

- Advise patient to take alendronate in the morning with a full glass of water. Explain that beverages such as orange juice, coffee, and mineral water reduce alendronate's effects.
- Instruct patient who is prescribed the effervescent tablet form to dissolve the tablet in 4 ounces of room-temperature water (mineral water or flavored water should not be used). After the effervescence stops, tell the patient to wait 5 minutes and then stir the solution for about 10 seconds and ingest.
- Tell patient not to chew or suck on tablet to help reduce esophageal irritation.
- Instruct patient to wait at least 30 minutes after taking alendronate before eating, drinking, or taking other drugs. Teach patient to remain

upright for 30 minutes after taking alendronate and until she has eaten the first food of the day.

- Encourage patient to consume adequate daily amounts of calcium and vitamin D.
- Instruct patient to report to prescriber any new or unusual pain in hip or thigh.
- Tell patient to inform dentist of alendronate therapy prior to dental work and to notify dentist of any signs of infection or delayed healing after an extraction.
- Instruct patient to report any difficulty swallowing or pain when swallowing, chest pain, or new or worsening heartburn to prescriber.
- Inform patient receiving the effervescent tablet form to be aware that each tablet contains 650 mg sodium, which is equivalent to approximately 1,650 mg of salt (sodium chloride) per tablet.

## aliskiren

### Rasilez (CAN), Tekturna

## Class and Category

*Pharmacologic class:* Direct renin inhibitor

*Therapeutic class:* Antihypertensive

## Indications and Dosages

➤ *To treat hypertension*

### ORAL PELLETS, TABLETS

**Adults and children age 6 to 17 weighing 50 kg (110 lb) or more.** 150 mg once daily, increased to 300 mg once daily, as needed.

**Children age 6 to 17 weighing less than 50 kg (110 lb) but 20 kg (44 lb) or more.** 37.5 or 75 mg daily.

*Maximum:* 150 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	1–3 hr	Unknown

## Mechanism of Action

Inhibits renin secreted by the kidneys in response to decreased blood volume and renal perfusion. Renin cleaves angioten-sinogen to form angiotensin I, which is converted to angiotensin II by ACE and non-ACE pathways.

Angiotensin II is a powerful vasoconstrictor that induces release of catecholamines from the adrenal medulla and prejunctional nerve endings. It also promotes aldosterone secretion and sodium reabsorption. Together, these actions increase blood pressure. By inhibiting renin release, aliskiren impairs the renin-angiotensin-aldosterone system. Without the vasoconstrictive effect of angiotension II, blood pressure decreases.

## Contraindications

Children under the age of 2; hypersensitivity to aliskiren or its components, presence of diabetes and concurrent angiotensin-converting enzyme inhibitor (ACEI) or angiotensin receptor blocker (ARB) therapy, pregnancy

## Interactions

### DRUGS

*ACE inhibitors, ARBs:* Increased risk of hyperkalemia, hypotension or renal dysfunction, especially in the elderly

and patients who are volume-depleted or already have renal impairment

*atorvastatin, cyclosporine, itraconazole, ketoconazole, verapamil*: Increased aliskiren blood level

*furosemide*: Decreased blood furosemide levels

*irbesartan*: Decreased blood aliskiren level

*NSAIDs*: Increased risk of decreased renal function and hypotension

*P-glycoprotein*: Possible alteration in absorption and disposition of aliskiren at Pgp site

*potassium-sparing diuretics, potassium supplements*: Increased risk of hyperkalemia

## **FOODS**

*high-fat food*: Decreased aliskiren absorption substantially

## **Adverse Reactions**

**CNS**: Dizziness, fatigue, headache, **seizures**

**CV**: **Hypotension**, peripheral edema

**EENT**: Nasopharyngitis

**GI**: Abdominal pain, diarrhea, dyspepsia, elevated liver enzymes, gastroesophageal reflux, **hepatic dysfunction**, nausea, vomiting

**GU**: Elevated blood creatinine, renal calculi

**HEME**: Decreased hemoglobin and hematocrit

**MS**: Back pain

**RESP**: Increased cough, upper respiratory tract infection

**SKIN**: Erythema, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** Anaphylaxis, angioedema, elevated creatine kinase or uric acid level, gout, hyperkalemia, hyponatremia

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm, especially if exposure occurs during the second or third trimester.
- Drug reduces fetal renal function leading to anuria and renal failure and increases fetal and neonatal morbidity and death. It can also cause fetal lung hypoplasia, hypotension, and skeletal deformations such as skull hypoplasia.
- Drug is contraindicated in pregnant women and should be discontinued as soon as possible when pregnancy occurs.

### LACTATION

- It is not known if drug is present in breast milk.
- Drug is not recommended for use in breastfeeding women to avoid potential serious adverse reactions including hyperkalemia, hypotension, and renal impairment in the breastfed infant.

## Nursing Considerations

- Be aware that aliskiren should not be used in patients with diabetes who are concurrently taking ARBs or ACEIs because of the increased risk of serious adverse effects such as renal dysfunction, hyperkalemia, and hypotension. Also know that aliskiren should not be given to patients with moderate renal impairment (glomerular filtration rate of less than 60 ml/min) who are also receiving ARB or ACEI therapy because renal impairment may worsen.
- Monitor patient's renal function closely, especially in patients receiving drugs such as ARBs, ACEIs, NSAIDs, potassium supplements or potassium-sparing diuretics that affect the renin-angiotensin system. Use aliskiren cautiously in patients whose renal function may depend in part on the activity of this system such as those with renal artery stenosis,

severe heart failure, postmyocardial infarction, or who are elderly or experiencing volume depletion because aliskiren therapy increases the risk of renal dysfunction in these patients that could lead to acute renal failure.

- Take measures to correct volume or salt depletion from high-dose diuretic therapy before starting aliskiren, as ordered, to prevent hypotension. If hypotension occurs during aliskiren therapy, place patient in a supine position and give normal saline solution intravenously, as needed and prescribed.
- Expect to administer oral pellets for patients who are unable to swallow tablets. The pellets are dispensed in a capsule. Open the dispensing capsule, empty the contents onto a spoon, and then administer by mouth. Have patient swallow the pellets immediately. Follow with milk (dairy or soy-based) or water immediately without patient chewing or crushing the pellets. Make sure that no pellets remain in the dispensing capsule. Never give the capsule containing the oral pellets for patient to swallow and do not empty the contents of the capsule directly into patient's mouth. Alternatively, after opening the dispensing capsule, pellets can be immediately mixed with one or more teaspoons of milk that is dairy or soy-based, vanilla ice cream, vanilla pudding, or water as a dosing vehicle. Have patient take the contents of one dispensing capsule with one teaspoon of dosing liquid. Again, ensure that patient does not chew or crush the pellets in mouth but swallows the pellets immediately.

**WARNING** Watch closely for angioedema of the head or neck. if angioedema occurs, discontinue aliskiren, notify prescriber, and provide supportive therapy until swelling has ceased. if swelling of the tongue, glottis, or larynx is involved, be prepared to give epinephrine solution 1:1,000 (0.3 to 0.5 ml), as prescribed, and provide measures to ensure a patent airway. Be aware that patient shouldn't receive aliskiren again.

- Monitor serum electrolytes, especially potassium levels, as ordered in patients who already are experiencing renal insufficiency or who have diabetes because of increased risk for hyperkalemia in the presence of aliskiren therapy. Also monitor patients who are taking ARBs, ACEIs, or NSAIDs along with aliskiren because of increased risk of hyperkalemia.

## **PATIENT TEACHING**

- Tell patient who is unable to swallow tablets that aliskiren can be taken by oral pellets. Tell him the pellets are dispensed in a capsule. After opening the dispensing capsule, tell him to empty the contents onto a spoon and then administer by mouth and swallow immediately. He should follow with milk (dairy or soy-based) or water immediately without chewing or crushing the pellets. He should check to make sure that no pellets remain in the dispensing capsule. He should never take the capsule containing the oral pellets and he should never empty the contents of the capsule directly into his mouth. Alternatively, tell him the pellets, after opening the dispensing capsule, can be immediately mixed with one or more teaspoons of milk that is dairy or soy-based, vanilla ice cream, vanilla ice pudding, or water as a dosing vehicle. He should mix the contents of one dispensing capsule with one teaspoon of dosing liquid. Again, he should not chew or crush the pellets in mouth but swallow the mixture immediately.
- Advise patient to avoid high-fat meals while taking aliskiren because fat decreases drug absorption significantly.
- Instruct patient how to monitor blood pressure to determine effectiveness of aliskiren therapy.
- Explain that decreased blood pressure could lead to light-headedness, especially in the first few days of therapy. Advise patient to change positions slowly and, if light-headedness develops, to notify prescriber. Tell patient to stop taking aliskiren and to notify prescriber if she faints.
- Explain that light-headedness and fainting could also result from dehydration caused by inadequate fluid intake, excessive perspiration, diarrhea, or vomiting.
- Instruct patient to avoid using potassium supplements or potassium salt substitutes and to inform all prescribers about her aliskiren and ACE inhibitor or ARD therapy.

**WARNING** Emphasize importance of stopping aliskiren and seeking immediate medical attention if patient has swelling of face, extremities, eyes, lips, or tongue, or if patient has trouble swallowing or breathing.

- Instruct female patient to notify prescriber immediately if she is or could be pregnant because drug will need to be discontinued and another antihypertensive chosen. Also inform mothers that breastfeeding is not recommended while taking aliskiren, as drug can cause high potassium level, kidney impairment, and low blood pressure in a nursing infant.

# allopurinol

**Apo-Allopurinol (CAN), Lopurin,  
Purinol (CAN), Zyloprim**

# allopurinol sodium

**Aloprim**

## Class and Category

*Pharmacological class:* Xanthine oxidase inhibitor

*Therapeutic class:* Antigout

## Indications and Dosages

- *To treat primary gout and hyperuricemia*

### **TABLETS**

**Adults.** *Initial:* 100 mg daily increased by 100 mg/wk until serum uric acid level is 6 mg/dl or less. Dosages above 300 mg daily given in divided doses. *Maximum:* 800 mg daily.

- *To treat secondary hyperuricemia caused by neoplastic disease*

### **TABLETS**

**Adults.** 600 to 800 mg daily for 2 to 3 days, then adjusted to keep serum uric acid level within normal limits.

**Children ages 6 to 10.** 300 mg daily, adjusted after 48 hr, depending on response to treatment.

**Children under age 6.** 150 mg daily, adjusted after 48 hr, depending on response to treatment.

➤ *To treat recurrent calcium oxalate calculi*

## TABLETS

**Adults.** 200 to 300 mg daily as a single dose or in divided doses, adjusted based on 24-hr urine urate level.

➤ *To treat increased serum and urine uric acid levels in patients with leukemia, lymphoma, and solid tumors whose cancer chemotherapy has increased those levels and who can't tolerate oral therapy*

## I.V. INFUSION

**Adults.** 200 to 400 mg/m<sup>2</sup> daily as a single infusion or in equally divided infusions every 6, 8, or 12 hr. *Maximum:* 600 mg daily.

**Children.** 200 mg/m<sup>2</sup> daily as a single infusion or in equally divided infusions every 6, 8, or 12 hr.

***DOSAGE ADJUSTMENT*** For patient with impaired renal function, dosage adjusted to 200 mg daily if creatinine clearance is 10 to 20 ml/min, 100 mg daily if creatinine clearance is 3 to 10 ml/min, or 100 mg every other day if creatinine clearance falls below 3 ml/min.

Route	Onset	Peak	Duration
P.O.	2-3 days	1-3 wk*	1-2 wk
I.V.	10-15 min	Unknown	5 hr

\* For hyperuricemia; several months for gout attack prevention.

## Mechanism of Action

Inhibits uric acid production by inhibiting xanthine oxidase, the enzyme that converts hypoxanthine and xanthine to uric acid. Allopurinol is metabolized to oxipurinol, which also inhibits xanthine oxidase.

## Incompatibilities

Don't combine I.V. allopurinol in solution with amikacin, amphotericin B, carmustine, cefotaxime sodium, chlorpromazine hydrochloride, cimetidine hydrochloride, clindamycin phosphate, cytarabine, dacarbazine, daunorubicin hydrochloride, diphenhydramine hydrochloride, doxorubicin hydrochloride, doxycycline hyclate, droperidol, floxuridine, gentamicin sulfate, haloperidol lactate, hydroxyzine hydrochloride, idarubicin hydrochloride, imipenem-cilastatin sodium, mechlorethamine hydrochloride, meperidine hydrochloride, metoclopramide hydrochloride, methylprednisolone sodium succinate, minocycline hydrochloride, nalbuphine hydrochloride, netilmicin sulfate, ondansetron hydrochloride, prochlorperazine edisylate, promethazine hydrochloride, sodium bicarbonate, streptozocin, tobramycin sulfate, vinorelbine tartrate.

## Contraindications

Hypersensitivity to allopurinol or its components

## Interactions

### DRUGS

*ACE inhibitors:* Increased risk of hypersensitivity reactions  
*amoxicillin, ampicillin:* Increased risk of rash

*azathioprine, mercaptopurine*: Increased plasma levels of these drugs with increased risk of toxicity

*chlorpropamide*: Increased risk of hypoglycemia in patients with renal insufficiency

*cyclophosphamide, other cytotoxic drugs*: Enhanced bone marrow suppression

*dicumarol*: Increased half-life and anticoagulant action of dicumarol

*thiazide diuretics*: Possibly increased risk of allopurinol toxicity

*uricosuric agents*: Increased urinary excretion of uric acid

## **Adverse Reactions**

**CNS**: Chills, drowsiness, fever, headache, neuritis, paresthesia, peripheral neuropathy, somnolence

**CV**: Vasculitis

**EENT**: Epistaxis, loss of taste

**GI**: Abdominal pain, diarrhea, dysphagia, elevated liver enzymes, gastritis, **granulomatous hepatitis, hepatic necrosis**, hepatomegaly, nausea, vomiting

**GU**: Exacerbated renal calculi, **renal failure**

**HEME**: **Agranulocytosis, aplastic anemia, bone marrow depression**, eosinophilia, leukocytosis, **leukopenia, thrombocytopenia**

**MS**: Arthralgia, exacerbation of gout, myopathy

**SKIN**: Alopecia; ecchymosis; jaundice; maculopapular, scaly, or exfoliative rash (sometimes fatal); pruritus; urticaria

**OTHER**: Drug hypersensitivity syndrome (DHS), drug reaction with eosinophilia and systemic symptoms (DRESS)

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Obtain baseline CBC and uric acid level, as ordered, and review results of renal and liver function tests before and during allopurinol therapy.
- Reconstitute and dilute I.V. preparation to a concentration of 6 mg/ml or less.

**WARNING** Discontinue allopurinol and notify prescriber immediately at first sign of hypersensitivity reaction, such as rash, which may precede more severe reactions.

- Maintain a fluid intake to produce a daily urinary output of 2 L daily. Also, don't give vitamin C because the pH of urine should be kept neutral to slightly alkaline.
- Monitor patient for the development of a skin rash that may occur 1 week or more after allopurinol therapy is initiated. If present, notify prescriber immediately because this could be a sign of DRESS, which may become life-threatening. Expect drug to be discontinued.

## PATIENT TEACHING

- Advise patient to take allopurinol after meals and to drink enough water (8 to 10 full glasses) to produce a daily urinary output of at least 2 L.
- Instruct patient to report unusual bleeding or bruising, chills, fever, gout attack, numbness, and tingling.
- Inform patient that acute gout attacks may occur more often early in allopurinol treatment and that results may not be noticeable for 2 weeks or longer.
- Instruct patient not to drive or perform hazardous tasks if drug causes drowsiness.
- Tell patient to notify prescriber immediately if a rash develops and to stop taking drug until the rash is evaluated.

## almotriptan malate

**Axert**

### Class and Category

*Pharmacologic class:* Selective serotonin receptor agonist (5-T<sub>1</sub>)

*Therapeutic class:* Antimigraine drug

### Indications and Dosages

➤ *To treat acute migraine*

#### **TABLETS**

**Adults and adolescents ages 12 to 17.**

*Initial:* 6.25 or 12.5 mg as a single dose, repeated in 2 hr as needed. *Maximum:* 25 mg/24 hr or 4 migraine treatments/mo.

**DOSAGE ADJUSTMENT** For patient with impaired hepatic or renal function or patients receiving potent CYP3A4 inhibitors such as ketoconazole, initial dose reduced to 6.25 mg with maximum daily dose of 12.5 mg.

## Mechanism of Action

May stimulate 5-HT<sub>1</sub> receptors on intracranial blood vessels and sensory nerves in trigeminal vascular system. By activating these receptors, almotriptan selectively constricts dilated and inflamed cranial blood vessels and inhibits production of proinflammatory neuropeptides. It also interrupts transmission of pain signals to the brain.

## Contraindications

Basilar or hemiplegic migraine, cerebrovascular, or peripheral vascular disease, hypersensitivity to almotriptan or its components, hypertension (uncontrolled), ischemic or vasospastic coronary artery disease (CAD), use within 24 hours of other serotonin-receptor agonists or ergotamine-containing or ergot-type drugs

## Interactions

### DRUGS

*ergotamine-containing drugs*: Prolonged vasospastic reactions

*erythromycin, itraconazole, ketoconazole, MAO inhibitors, ritonavir, verapamil*: Possibly increased blood almotriptan level

*selective serotonin reuptake inhibitors (such as citalopram, escitalopram, fluoxetine, fluvoxamine, paroxetine, sertraline)*,

*serotonin norepinephrine reuptake inhibitors (such as duloxetine, venlafaxine): Increased risk of serotonin syndrome*

## Adverse Reactions

**CNS:** Confusion, dizziness, headache, hemiplegia, hypoesthesia, malaise, paresthesia, restlessness, **seizures**, **serotonin syndrome**, somnolence, syncope, vertigo

**CV:** Angina pectoris, **coronary artery vasospasm**, hypertension, **ischemia**, **MI**, palpitations, tachycardia, vasodilation, **ventricular fibrillation or tachycardia**

**EENT:** Blepharospasm, dry mouth, oral hypoesthesia, swollen tongue, visual impairment

**GI:** Abdominal pain or discomfort, colitis, nausea

**MS:** Arthralgia, extremity coldness or pain, myalgia

**SKIN:** Cold sweat, diaphoresis, erythema

**Other:** **Anaphylaxis**, **angioedema**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

**WARNING** Monitor patient with CAD for angina because almotriptan can cause coronary artery vasospasm. Because it may cause peripheral vasospastic reactions, such as ischemic bowel disease, watch for abdominal pain and bloody diarrhea.

- Expect to give first dose of almotriptan in a medical facility for patient with risk factors for CAD but no known cardiovascular abnormalities.
- Obtain an ECG immediately after first dose of almotriptan, as ordered, in patient with risk factors for CAD because cardiac ischemia can occur without causing clinical symptoms.
- Expect to give a lower dosage to patients with hepatic or renal dysfunction because of impaired drug metabolism or excretion.
- Monitor blood pressure regularly during therapy in patients with hypertension because almotriptan may produce a transient increase in blood pressure.

**WARNING** Monitor patient for evidence of serotonin syndrome, such as agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. In its most severe form, serotonin syndrome can resemble neuroleptic malignant syndrome, which includes autonomic instability with possible fluctuations in vital signs, high fever, mental status changes, and muscle rigidity.

- Monitor patients hypersensitive to sulfonamides for hypersensitivity to almotriptan because cross-sensitivity may occur.

## PATIENT TEACHING

- Inform patient that almotriptan is used to treat acute migraine and that he shouldn't take it to treat nonmigraine headaches.
- Advise patient to consult prescriber before taking any OTC or prescription drugs.
- Advise patient not to take more than maximum prescribed dosage, as medication overuse can cause migraine-like daily headaches or a marked increase in frequency of migraine attacks requiring detoxification to treat, which could lead to withdrawal symptoms.
- Caution patient that drug may cause adverse CNS reactions, and advise him to avoid hazardous activities until he knows how drug affects him.
- Instruct patient to seek emergency care immediately for signs of hypersensitivity such as breathing difficulties, itching, or a rash; cardiac symptoms (such as heaviness, pain, pressure, or tightness in chest, jaw, neck, or throat); or if multiple new symptoms develop (such as diarrhea, high fever, incoordination, mental changes nausea, vomiting) after taking the drug.
- Advise women of childbearing age to notify prescriber if pregnancy is suspected or occurs. Also advise mothers who wish to breastfeed to discuss with prescriber first.

**alogliptin**

**Nesina**

## **Class and Category**

*Pharmacologic class:* Dipeptidyl peptidase-4 (DPP-4) inhibitor

*Therapeutic class:* Oral antidiabetic

## **Indications and Dosages**

- *To achieve control of glucose level in type 2 diabetes mellitus as monotherapy or in conjunction with combination therapy*

## **TABLETS**

**Adults.** 25 mg once daily.

***DOSAGE ADJUSTMENT*** For patients with moderate renal impairment (creatinine clearance less than 60 ml/min but equal to or greater than 30 ml/min), dosage decreased to 12.5 mg once daily. For patients with severe renal impairment (creatinine clearance less than 30 ml/min but equal to or greater than 15 ml/min) or patients with end-stage renal disease or who are on hemodialysis, dosage decreased to 6.25 mg once daily.

## **Mechanism of Action**

Inhibits the dipeptidyl peptidase-4 enzyme to slow inactivation of incretin hormones. These hormones are released by the intestine in response to a meal. When blood glucose level is increased, incretin hormones increase insulin synthesis and release from pancreatic beta cells. One type of incretin hormone, glucagon-like peptide (GLP-1), also lowers glucagon secretion from pancreatic alpha cells, which reduces hepatic glucose production. These combined actions decrease blood glucose level in type 2 diabetes.

## **Contraindications**

Diabetic ketoacidosis; hypersensitivity to alogliptin or its components including anaphylaxis, angioedema, or severe cutaneous adverse reactions; type 1 diabetes

# Interactions

## DRUGS

*insulin, sulfonylureas*: Possibly increased risk of hypoglycemia

# Adverse Reactions

**CNS:** Headache

**CV:** **Heart failure**

**EENT:** Nasopharyngitis

**ENDO:** **Hypoglycemia**

**GI:** **Acute pancreatitis**, constipation, diarrhea, elevated liver enzymes, **fulminant hepatic failure**, ileus, nausea

**MS:** Arthralgia (disabling and severe), joint pain (severe), **rhabdomyolysis**

**RESP:** Upper respiratory tract infection

**SKIN:** Bullous pemphigoid, rash, **Stevens-Johnson syndrome**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, serum sickness

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use alogliptin cautiously in patients with a history of angioedema to another drug in the same class because it is not known if patient will be predisposed to angioedema with alogliptin therapy.
- Determine patient's history for prior history of heart failure and a history of renal impairment because drug may increase risk for heart failure.
- Assess patient's renal function before starting alogliptin therapy. Know that in moderate to severe renal dysfunction, dosage will need to be reduced.
- Assess patient's liver function before starting alogliptin therapy. If abnormalities are present, monitor patient closely for signs and symptoms of liver dysfunction. If patient develops anorexia, dark urine, fatigue, jaundice, or right upper abdominal discomfort during therapy, notify prescriber and expect liver enzymes to be assessed. If elevated, expect drug to be discontinued.
- Monitor patient for serious hypersensitivity reactions, including severe cutaneous adverse reactions. If present, notify prescriber, expect alogliptin to be discontinued, and provide supportive care, as ordered.
- Check patient's blood glucose level, as ordered, to determine effectiveness of alogliptin therapy.

**WARNING** Monitor patient for signs and symptoms of acute pancreatitis, such as acute upper abdominal pain, fever, nausea, and vomiting. If suspected, notify prescriber and expect alogliptin to be discontinued, if confirmed.

## PATIENT TEACHING

- Emphasize the need to follow an exercise program and a diet control program during alogliptin therapy.

- Advise patient to notify prescriber immediately if he has trouble breathing, develops swelling or skin reactions such as hives, rash, or other cutaneous abnormalities.
- Inform patient that periodic blood tests will be done to determine effectiveness of drug.
- Teach patient how to monitor blood glucose level and when to report changes.
- Caution patient that taking other drugs used to decrease blood glucose level may lead to hypoglycemia. Review signs, symptoms, and appropriate treatment.
- Instruct patient to contact prescriber if he develops other illnesses, such as infection, or experiences trauma or surgery, because his diabetes medication may need adjustment.
- Advise patient to carry identification indicating that he has diabetes.
- Instruct patient to stop taking alogliptin and to report persistent severe abdominal pain, possibly radiating to the back, that may or may not be accompanied by vomiting.
- Alert patient that if severe joint pain occurs, he should notify prescriber as alogliptin may need to be discontinued.
- Review signs and symptoms of heart failure with patient and instruct her to notify prescriber immediately if present.

## alprazolam

**Alprazolam Intensol, Apo-Alpraz (CAN), Novo-Alprazol (CAN), Xanax, Xanax TS (CAN), Xanax XR**

### **Class, Category, and Schedule**

*Pharmacologic class:* Benzodiazepine

*Therapeutic class:* Anxiolytic, antipanic

*Controlled substance schedule: IV*

## Indications and Dosages

- *To control anxiety disorders, relieve anxiety (short-term therapy), or treat anxiety associated with depression*

### ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS

**Adults.** *Initial:* 0.25 to 0.5 mg three times daily and increased, as needed, every 3 to 4 days. *Maximum:* 4 mg daily in divided doses.

***DOSAGE ADJUSTMENT*** In elderly or debilitated patients or patients with advanced hepatic disease, initial dosage 0.25 mg twice daily or three times daily and increased gradually, as needed and tolerated.

- *To treat panic disorder*

### ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS

**Adults.** *Initial:* 0.5 mg three times daily, increased every 3 to 4 days by no more than 1 mg daily, based on patient response. *Maximum:* 10 mg in equally divided doses three or four times daily.

### E.R. TABLETS

**Adults.** *Initial:* 0.5 to 1 mg daily in morning, increased every 3 to 4 days by no more than 1 mg daily, based on patient response. *Maximum:* 10 mg daily as single dose in morning.

## Mechanism of Action

May increase effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptors in cortical and limbic areas of the CNS. GABA inhibits excitatory stimulation, which helps control emotional behavior. The limbic system contains many benzodiazepine receptors, which may help explain drug's antianxiety effects.

## Contraindications

Acute angle-closure glaucoma; hypersensitivity to alprazolam, its components, or other benzodiazepines; itraconazole or ketoconazole therapy

## Interactions

### DRUGS

*amiodarone, cyclosporine, diltiazem, ergotamine, isoniazid, macrolide antibiotics (clarithromycin, erythromycin), nicardipine, nifedipine, paroxetine, sertraline*: Possible alteration in alprazolam plasma levels  
*antacids*: Altered alprazolam absorption rate  
*anticonvulsants; antidepressants; antihistamines; other benzodiazepines, CNS depressants, and psychotropics*: Possibly increased CNS depressant effects  
*carbamazepine*: Decreased plasma level of alprazolam and potential decreased effectiveness  
*cimetidine, fluoxetine, oral contraceptives, propoxyphene*: Decreased alprazolam elimination and increased effects  
*digoxin*: Possibly increased serum digoxin level, causing digitalis toxicity

*itraconazole, ketoconazole*: Possibly profoundly inhibited alprazolam metabolism

*opioids*: Increased risk of significant respiratory depression

*phenytoin*: Possibly increased serum phenytoin level, causing phenytoin toxicity

## ACTIVITIES

*alcohol use*: Enhanced adverse CNS effects of alprazolam; increased risk of significant sedation and somnolence, especially if combined with an opioid

## Adverse Reactions

**CNS**: Agitation, akathisia, confusion, depression, dizziness, drowsiness, fatigue, hallucinations, headache, insomnia, irritability, lack of coordination, light-headedness, memory loss, nervousness, paresthesia, rigidity, speech problems, syncope, tremor, weakness

**CV**: Chest pain, edema, **hypotension**, nonspecific ECG changes, palpitations, peripheral edema, tachycardia

**EENT**: Blurred vision, altered salivation, dry mouth, nasal congestion, tinnitus

**ENDO**: Galactorrhea, gynecomastia, hyperprolactinemia

**GI**: Abdominal discomfort, anorexia, constipation, diarrhea, elevated liver function test results, **hepatitis**, **hepatic failure**, nausea, vomiting

**GU**: Altered libido, urinary hesitancy

**MS**: Dysarthria, muscle rigidity and spasms

**RESP**: Hyperventilation, upper respiratory tract infection

**SKIN**: Dermatitis, diaphoresis, pruritus, rash, **Stevens-Johnson syndrome**

**Other:** **Angioedema**, weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Drug can potentially cause fetal harm, especially congenital abnormalities, when taken during the first trimester of pregnancy. Confirmed or suspected pregnancy should be immediately reported to prescriber.
- Drug also should be avoided throughout pregnancy as neonate may be at some risk for withdrawal symptoms from exposure to the drug in utero. Flaccidity and respiratory problems have also been reported in the neonate exposed to drug in utero.

### LABOR & DELIVERY

- Drug has no established use during labor and delivery.

### LACTATION

- Drug may be present in breast milk as other benzodiazepines are known to be present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential adverse reactions in the breastfed infant as chronic intake of drug in breast milk may cause infants to become lethargic and to lose weight.

## Nursing Considerations

**WARNING** Be aware that opioid therapy should only be used concomitantly with alprazolam in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of the opioid to be limited. Monitor patient closely for signs and symptoms of decrease in consciousness, including coma, profound

sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

- Expect to give a higher dosage if patient's panic attacks occur unexpectedly or during such activities as driving.
- Plan to reduce dosage slowly when alprazolam is discontinued, as ordered, because use can lead to dependency.

## PATIENT TEACHING

- Warn against stopping drug abruptly because withdrawal symptoms may occur.
- Instruct patient never to increase prescribed dose because of risk of dependency.
- Tell patient prescribed orally disintegrating tablets to use dry hands to remove tablet from bottle just prior to administration. Then she should immediately place the tablet on top of her tongue to dissolve. Inform patient that drinking a liquid beverage is not necessary after taking this form of alprazolam.

**WARNING** Warn patient not to consume alcohol or take an opioid during alprazolam treatment without prescriber knowledge, as severe respiratory depression can occur and may lead to death.

**WARNING** Inform patient about potentially fatal additive effects of combining alprazolam with an opioid. Instruct patient to inform all prescribers of alprazolam use, especially if pain medication may be prescribed.

- Advise patient to avoid driving and activities that require alertness until alprazolam's effects are known.
  - Instruct female patient of childbearing age to notify prescriber immediately if she becomes or might be pregnant. Drug isn't recommended during pregnancy.
-

# alteplase (tissue plasminogen activator, recombinant)

**Activase, Activase rt-PA (CAN),  
Cathflo Activase**

## Class and Category

*Pharmacologic class:* Tissue plasminogen activator (tPA)

*Therapeutic class:* Thrombolytic

## Indications and Dosages

- *To treat acute MI for reduction of mortality and incidence of heart failure*

### **I.V. INJECTION COMBINED WITH ACCELERATED I.V. INFUSION**

**Adults weighing more than 67 kg (148 lb).** 15-mg bolus followed by 50 mg infused over 30 min and then 35 mg infused over next 60 min. *Maximum:* 100 mg.

**Adults weighing 67 kg or less.** 15-mg bolus followed by 0.75 mg/kg (up to 50 mg) infused over 30 min and then 0.5 mg/kg (up to 35 mg) infused over next 60 min. *Maximum:* 100 mg.

### **I.V. INJECTION COMBINED WITH 3-HOUR I.V. INFUSION**

**Adults weighing more than 65 kg (143 lb).** 6 to 10 mg by bolus over first 1 to 2 min, then as an infusion, 50 to 54 mg over remainder of first hour, 20 mg over second hour, and 20 mg over third hour. *Maximum.* 100 mg.

**Adults weighing 65 kg or less.** 0.075 mg/kg by bolus over first 1 to 2 min, then as an infusion, 0.675 mg/kg over remainder of first hour, 0.25 mg/kg over second hour, and 0.25 mg/kg over third hour. *Maximum:* 100 mg.

- *To treat acute ischemic stroke within 3 hr after onset of stroke symptoms and only after computed tomography or other diagnostic imaging method excludes intracranial hemorrhage.*

## **I.V. INJECTION COMBINED WITH I.V. INFUSION**

**Adults.** 0.9 mg/kg infused over 60 min, with 10% of total dose given as bolus over first min. *Maximum:* 90 mg.

- *To treat acute massive pulmonary embolism*

## **I.V. INFUSION**

**Adults.** 100 mg infused over 2 hr.

- *To restore function of occluded central venous access devices*

## **I.V. INJECTION (CATHFLO ACTIVASE)**

**Adults and children weighing 30 kg (66 lb) or more.** 2 mg/2 ml instilled into occluded catheter; if unsuccessful, may repeat once after 2 hr.

**Adults and children weighing less than 30 kg (66 lb).** 110% of the lumen volume (not to exceed 2 mg/2ml) instilled into occluded catheter; if unsuccessful, may repeat once after 2 hr.

---

**Route**

**Onset**

**Peak**

**Duration**

Route	Onset	Peak	Duration
I.V.	Immediate	20-120 min	4 hr

## Mechanism of Action

Binds to fibrin in a thrombus and converts trapped plasminogen to plasmin. Plasmin breaks down fibrin, fibrinogen, and other clotting factors, which dissolves the thrombus.

## Incompatibilities

Don't add other drugs to solution that contains alteplase.

## Contraindications

*For all indications:* Active internal bleeding, arteriovenous malformation or aneurysm, bleeding diathesis, hypersensitivity to alteplase or its components, intracranial neoplasm, severe uncontrolled hypertension

*For acute MI and pulmonary embolism only:* History of stroke, intracranial or intraspinal surgery or trauma in past 3 months

*For acute ischemic stroke only:* Recent head trauma, recent intracranial or intraspinal surgery or trauma in past 3 months, recent stroke, seizure activity at onset of stroke, subarachnoid hemorrhage, suspicion or history of intracranial hemorrhage

## Interactions

### DRUGS

*angiotensin-converting enzyme (ACE) inhibitors*: Possible increased risk of angioedema

*anticoagulants, antiplatelets, vitamin K antagonists*: Increased risk of bleeding

## **Adverse Reactions**

**CNS:** Cerebral edema or herniation, CVA, fever, seizures

**CV:** Arrhythmias (including bradycardia and electromechanical dissociation), cardiac arrest, cardiac tamponade, cardiogenic shock, cholesterol embolism, coronary thrombolysis, heart failure, hypotension, mitral insufficiency, myocardial reinfarction or rupture, pericardial effusion, pericarditis, venous embolism or thrombosis

**EENT:** Epistaxis, gingival bleeding, laryngeal edema

**GI:** GI bleeding, nausea, retroperitoneal bleeding, vomiting

**GU:** GU bleeding

**HEME:** Bleeding that may be severe

**RESP:** Pleural effusion, pulmonary edema, pulmonary reembolization

**SKIN:** Bleeding at puncture sites, ecchymosis, rash, urticaria

**Other:** Anaphylaxis, angioedema

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug may cause fetal harm but some evidence suggests the possibility exists.
- Drug should only be used in pregnant women in life-threatening situations if no other safer alternative is available as pregnancy increases risk of bleeding.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding, once condition has stabilized, as its effect on the breastfed infant is unknown.

## Nursing Considerations

**WARNING** Know that treatment for acute ischemic stroke must begin within 3 hours after onset of stroke symptoms and only after computed tomography or other diagnostic imaging method excludes intracranial hemorrhage to avoid complications.

**WARNING** Monitor patient closely for hypersensitivity reactions which may be life-threatening (angioedema, laryngeal edema, rash, shock) during alteplase administration and for several hours after infusion is completed. If hypersensitivity occurs, discontinue the alteplase infusion immediately and institute appropriate emergency interventions such as administering antihistamines, epinephrine, or intravenous corticosteroids as prescribed.

- Reconstitute alteplase with sterile water for injection only immediately before use. Swirl gently to dissolve powder; don't shake.

**WARNING** Know that alteplase can cause internal bleeding that could be severe and sometimes fatal, as well as external bleeding, especially at arterial and venous puncture sites. Avoid intramuscular injections and

trauma to patient receiving drug. Discontinue alteplase immediately if serious bleeding occurs. Be aware that the following conditions increases risk: advanced age, especially if patient is currently receiving anticoagulant therapy; acute pericarditis; cerebrovascular disease; diabetic hemorrhagic retinopathy or other hemorrhagic ophthalmic conditions; hemostatic defects including those secondary to severe hepatic or renal disease; hypertension (diastolic above 110 mm/Hg or systolic above 175 mm Hg); pregnancy; recent gastrointestinal or genitourinary bleeding, intracranial hemorrhage, or trauma; septic thrombophlebitis or occluded AV cannula at seriously infected site; significant hepatic dysfunction; or subacute bacterial endocarditis.

- Minimize bleeding from noncompressible sites by avoiding internal jugular and subclavian venous puncture sites.
- Apply pressure at puncture site for at least 30 minutes, followed by a pressure dressing after administering alteplase.
- Assess blood pressure and heart rate and rhythm frequently during and after therapy.

**WARNING** Monitor continuous ECG for arrhythmias during drug therapy because alteplase therapy may cause arrhythmias from sudden reperfusion of the myocardium.

- Be aware that the use of thrombolytics such as alteplase can increase the risk of thromboembolic events in patients with high risk of left heart thrombus, such as patients with atrial fibrillation or mitral stenosis. Also know that the drug does not adequately treat underlying deep vein thrombosis in patients with a pulmonary embolism. Watch this type of patient closely for reembolization.
- Store reconstituted solution at room temperature (about 30°C [86°F]) or refrigerated (2.2° to 7.7°C [(36° to 46°F)]).
- Know that the most common complication of thrombolytic therapy is bleeding and that pregnancy may increase this risk. Monitor pregnant

patient closely for evidence of bleeding.

## PATIENT TEACHING

- Tell patient to immediately report bleeding, including from the nose or gums.
- Advise patient to limit physical activity during alteplase administration to reduce risk of injury and bleeding.

## aluminum carbonate

**Basaljel**

## aluminum hydroxide

**Alternagel, Alu-Cap, Alugel (CAN),  
Alu-Tab, Amphojel, Dialume**

## Class and Category

*Pharmacologic class:* Aluminum salt

*Therapeutic:* Antacid, phosphate binder

## Indications and Dosages

- *To treat hyperacidity associated with gastric hyperacidity, gastritis, hiatal hernia, peptic esophagitis, and peptic ulcers; to prevent phosphate renal calculus formation*

## **CAPSULES, SUSPENSION, TABLETS (ALUMINUM CARBONATE)**

**Adults.** 2 capsules or tablets or 10 ml suspension every 2 hr up to 12 times daily, as needed.

## **CAPSULES, TABLETS (ALUMINUM HYDROXIDE)**

**Adults.** 500 to 1,500 mg in divided doses 3 to 6 times daily, taken between meals and at bedtime.

## **SUSPENSION**

**Adults.** 5 to 30 ml, as needed, taken between meals and at bedtime.

➤ *To reduce hyperphosphatemia in chronic renal failure*

## **ORAL SUSPENSION**

**Adults.** 300 mg to 600 mg three times daily.

**Children.** 50 to 150 mg/kg/day in 4 to 6 divided doses.

Route	Onset	Peak	Duration
P.O.	Varies	Unknown	20-40 min*

If fasting; at least 3 hr if given 1 hr after meals.

## **Mechanism of Action**

Neutralizes or reduces gastric acidity, increasing stomach and duodenal alkalinity. Protects stomach and duodenum lining by inhibiting pepsin's proteolytic activity. Binds with phosphate ions in intestine to form insoluble aluminum-phosphate compounds, which lower blood phosphate level.

## **Contraindications**

Hypersensitivity to aluminum or its components

## Interactions

### DRUGS

*allopurinol, chloroquine, corticosteroids, diflunisal, digoxin, ethambutol, H<sub>2</sub>-receptor blockers, iron, isoniazid, phenothiazines, tetracyclines, thyroid hormones, ticlopidine*: Decreased effects of these drugs  
*benzodiazepines*: Increased benzodiazepine effects

## Adverse Reactions

**CNS:** Encephalopathy

**GI:** Constipation, intestinal obstruction, white-speckled stool

**MS:** Osteomalacia, osteoporosis

**Other:** Aluminum intoxication, electrolyte imbalances

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Don't give aluminum hydroxide within 1 to 2 hours of other oral drugs.
- Know that two 0.6-g aluminum hydroxide tablets can neutralize 16 mEq of acid.
- Monitor patient's serum levels of sodium, phosphate, and other electrolytes, as appropriate.

## PATIENT TEACHING

- Instruct patient to chew tablets thoroughly before swallowing and then to drink a full glass of water.
- Warn patient not to take maximum dosage for more than 2 weeks unless prescribed because doing so may cause stomach to secrete excess hydrochloric acid.
- Teach patient to prevent constipation with a high-fiber diet and increased fluid intake (2 to 3 L daily), if appropriate.
- Advise patient to notify prescriber about taking other medications and supplements before taking aluminum because of risk of interactions.
- Advise patient to notify prescriber if symptoms worsen or don't subside.

**amantadine**

**Gocovri, Osmolex ER**

**amantadine hydrochloride  
(adamantanamine  
hydrochloride)**

## Class and Category

*Pharmacologic class:* Dopamine agonist

*Therapeutic class:* Antidyskinetic, antiviral

## Indications and Dosages

- *To manage symptoms of primary Parkinson's disease, postencephalitic Parkinsonism, arteriosclerotic Parkinsonism, and Parkinsonism caused by CNS injury from carbon monoxide intoxication*

### CAPSULES, TABLETS

**Adults who do not have serious medical illnesses or who are not receiving high doses of other antiparkinson drugs.** 100 mg twice daily and increased, as needed.

**Adults with serious associated medical illnesses or who are receiving high doses of other antiparkinson drugs.** 100 mg once daily, increased after 1 to several weeks to 100 mg twice daily, if needed. *Maximum:* 400 mg daily in divided doses.

- *To treat drug-induced extrapyramidal reactions*

### CAPSULES, TABLETS

**Adults.** *Initial:* 100 mg twice daily and then increased, as needed. *Maximum:* 300 mg daily in divided doses.

- *To prevent and treat respiratory tract infection caused by influenza A virus*

### CAPSULES, TABLETS

**Adults up to age 65 and children age 12 and over.**

*Initial:* 200 mg daily or 100 mg twice daily and continued

for at least 10 days following exposure or, if used in conjunction with inactivated influenza A virus vaccine, until protective antibody responses develop, continued for 2 to 4 wk after vaccine has been given. Treatment started as soon as possible, preferably within 24 to 48 hr after onset of signs and symptoms and continued for 24 to 48 hr after signs and symptoms disappear. *Maximum:* 200 mg daily.

**Adults age 65 and over.** 100 mg daily and continued for at least 10 days following exposure or, if used in conjunction with inactivated influenza A virus vaccine, until protective antibody responses develop, continued for 2 to 4 wk after vaccine has been given. Treatment should be started as soon as possible, preferably within 24 to 48 hr after onset of signs and symptoms, and should be continued for 24 to 48 hr after signs and symptoms disappear.

**Children ages 9 to 12.** 100 mg every 12 hr, started in anticipation of an influenza A outbreak and before or after contact with individuals with influenza A virus respiratory tract illness. Treatment started as soon as possible, preferably within 24 to 48 hr after onset of signs and symptoms and continued for 24 to 48 hr after signs and symptoms disappear. *Maximum:* 200 mg daily.

**Children ages 1 to 9.** 2.2 to 4.4 mg/kg every 12 hr, started in anticipation of an influenza A outbreak and before or after contact with individuals with influenza A virus respiratory tract illness. Treatment started as soon as possible, preferably within 24 to 48 hr after onset of signs and symptoms and continued for 24 to 48 hr after signs and symptoms disappear. *Maximum:* 150 mg/day.

**DOSAGE ADJUSTMENT (AMANTADINE)** For all indications in adult patient with a creatinine clearance of 30 to 50 ml/min, 200 mg on day 1 and then 100 mg daily. For patient with a creatinine clearance of 15 to 29 ml/min, 200 mg on day 1 and then 100 mg every other day. For patient with creatinine clearance less than 15 ml/min or patient on

hemodialysis, 200 mg weekly. For patients with congestive heart failure, orthostatic hypotension, or peripheral edema, dosage may have to be reduced. For patient who develops central nervous system adverse effects or other effects while taking 200 mg once daily dose, dosage split into 100 mg twice daily.

- *To treat dyskinesia in patients with Parkinson's disease receiving levodopa-based therapy*

## **E.R. CAPSULES (GOCOVRI)**

**Adults.** *Initial:* 137 mg once daily at bedtime. After 1 wk, increased to 274 mg once daily at bedtime.

***DOSAGE ADJUSTMENT (GOCOVRI)*** For patient with a creatinine clearance of 30 to 59 ml/min, initial dosage reduced to 68.5 mg once daily at bedtime, with maximum dosage not to exceed 137 mg once daily at bedtime. For patient with a creatinine clearance of 15 to 29 ml/min, dosage reduced to 68.5 mg once daily at bedtime with no increased dosage adjustment.

- *To treat Parkinson's disease; to treat drug-induced extrapyramidal reactions*

## **E.R. TABLETS (OSMOLEX ER)**

**Adults.** *Initial:* 129 mg once daily in morning with dosage increased weekly to 322 mg, as needed. *Maximum:* 322 mg given as a 129 mg and 193 mg tablet in morning.

***DOSAGE ADJUSTMENT (OSMOLEX ER)*** For patient with a creatinine clearance of 30 to 59 ml/min, dosage titration done every 3 weeks instead of weekly and dosing frequency increased to one dose every 48 hours. For patients with a creatinine clearance of 15 to 29 ml/min, dosage titration interval increased to every 4 weeks instead of weekly, and dosing frequency increased to one dose every 96 hours.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.	In 48 hr*	Unknown	Unknown

\* Antidyskinetic action; antiviral action unknown.

## Mechanism of Action

Affects dopamine, a neurotransmitter that is synthesized and released by neurons leading from substantia nigra to basal ganglia and is essential for normal motor function. In Parkinson's disease, progressive degeneration of these neurons reduces intrasynaptic dopamine. Amantadine may cause dopamine to accumulate in the basal ganglia by increasing dopamine release or by blocking dopamine reuptake into the presynaptic neurons of the CNS. Amantadine also may stimulate dopamine receptors or make postsynaptic receptors more sensitive to dopamine. These actions help control alterations in involuntary muscle movements, such as tremors and rigidity, that are associated with Parkinson's disease.

Amantadine may inhibit influenza A viral replication by blocking uncoating of virus and release of viral nucleic acid into respiratory epithelial cells. It also may interfere with early replication of viruses that have already penetrated cells.

## Contraindications

End-stage renal disease (Gocovri, Osmolex ER only), hypersensitivity to amantadine or its components

## Interactions

### DRUGS

*anticholinergics or other drugs with anticholinergic activity:* Possibly increased anticholinergic effects and risk of paralytic ileus

*CNS stimulants:* Excessive CNS stimulation, possibly causing arrhythmias, insomnia, irritability, nervousness, or seizures

*live-virus vaccines:* Possibly interference with vaccine effectiveness

*quinidine, quinine, trimethoprim-sulfamethoxazole:* Increased blood amantadine level

*urine acidifying drugs:* Increased elimination of amantadine with possible decrease in effectiveness

*urine alkaline drugs:* Decreased elimination of amantadine with possible increase in adverse reactions

## ACTIVITIES

*alcohol use:* Possibly increased risk of CNS effects such as confusion, dizziness, light-headedness and orthostatic hypotension

## Adverse Reactions

**CNS:** Agitation, amnesia, anxiety, ataxia, confusion, depression, dizziness, dream abnormalities, drowsiness, euphoria, fatigue, fever, hallucinations, headache, hypokinesia, insomnia, irritability, light-headedness, mental impairment, nervousness, **neuroleptic malignant syndrome**, nightmares, psychiatric behavior, **seizures**, slurred speech, somnolence, **suicidal ideation**, syncope, weakness

**CV:** **Arrhythmias**, **cardiac arrest**, **congestive heart failure**, hypertension orthostatic hypotension, peripheral edema, tachycardia

**EENT:** Blurred vision; corneal edema or opacity; dry mouth, nose, or throat; keratitis; light sensitivity; mydriasis; optic nerve palsy

**GI:** Anorexia, constipation, diarrhea, dysphagia, nausea, vomiting

**GU:** Decreased libido, dysuria, urinary retention

**HEME:** Agranulocytosis, leukopenia, neutropenia

**RESP:** Acute respiratory failure, pulmonary edema, tachypnea

**SKIN:** Diaphoresis, eczematoid dermatitis, livedo reticularis (purplish, netlike rash), pruritus, rash

**Other:** Anaphylaxis; intense urges to perform certain activities, such as gambling or sexual acts

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm although some evidence exists that drug may have the potential to cause developmental issues, including cardiovascular, skeletal, and visceral malformations when administered in the first trimester.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Drug may alter breast milk excretion or production.
- Breastfeeding should not be undertaken during immediate-release drug therapy; patient should check with prescriber if taking extended release form before breastfeeding.

# Nursing Considerations

- Be aware that amantadine should not be used as the first drug of choice to prevent or treat influenza A because of high levels of resistance to the drug that has developed over the past several years.
- Monitor patients who have a history of psychiatric illness or substance abuse because amantadine may worsen these conditions. Some patients taking amantadine have attempted suicide or had suicidal ideation.
- Monitor for weight gain and edema because drug may cause redistribution of body fluid.
- Be aware that amantadine may increase seizure activity in patients with a history of seizures.

**WARNING** Monitor patient for evidence of neuroleptic malignant syndrome during dosage reduction or discontinuation of therapy. These include fever, hypertension or hypotension, involuntary motor activity, mental changes, muscle rigidity, tachycardia, and tachypnea. Be prepared to provide supportive treatment and additional drug therapy, as prescribed.

- Be aware that patients receiving more than 200 mg daily are more likely to experience adverse or toxic reactions.
- Monitor patient for decreased drug effectiveness over time. If therapeutic response declines, expect to increase dosage or discontinue drug temporarily, as ordered.
- Assess patient regularly for skin changes because melanoma risk is higher in those with Parkinson's disease. It isn't clear whether the risk is increased by the disease or by its treatment.

## PATIENT TEACHING

- Instruct patient to take amantadine exactly as prescribed and not to stop abruptly.
- Instruct patient taking Osmolex ER tablets to swallow tablets whole and not to chew, crush, or divide tablets. Advise patient to notify prescriber if drug becomes less effective.

- Tell patient to notify prescriber if influenza symptoms don't improve after 2 to 3 days.

**WARNING** Advise patient or family member to notify prescriber immediately if patient reveals thoughts of suicide.

- Encourage patient to avoid consuming alcohol during amantadine therapy because alcohol may increase the risk of confusion, dizziness, light-headedness, or orthostatic hypotension.
- Advise patient to avoid driving and other activities that require a high level of alertness until he knows how the drug affects him because it may cause blurred vision and mental impairment.
- Advise patient to change positions slowly to minimize effects of orthostatic hypotension.
- Tell patient to use ice chips or sugarless candy or gum to relieve dry mouth.
- Caution patient to resume physical activities gradually as signs and symptoms improve.
- Urge patient to have regular skin examinations by a dermatologist or other qualified health professional.
- Instruct patient to notify prescriber about intense urges, such as for gambling or sex, because dosage may need to be reduced or drug discontinued.

## amikacin sulfate

**Amikin, Arikayce**

### Class and Category

*Pharmacologic class:* Aminoglycoside

*Therapeutic class: Antibiotic*

## Indications and Dosages

- *To treat serious gram-negative bacterial infections (including bone, burns, CNS, joint, intra-abdominal, postoperative infections, respiratory tract, skin and soft-tissue; neonatal sepsis; septicemia; and serious, complicated, and recurrent UTI) caused by Acinetobacter, Enterobacter, Escherichia coli, Klebsiella, Proteus, Providencia, Pseudomonas, and Serratia; and susceptible strains of staphylococci in patients allergic to other antibiotics, and in mixed staphylococcal/gram-negative infections*

### I.V. INFUSION, I.M. INJECTION

**Adults and children.** 15 mg/kg daily in equal doses at equally spaced intervals (7.5 mg/kg every 12 hr or 5 mg/kg every 8 hr) for 7 to 10 days. I.V. infusion administered over 30 to 60 min.

**Neonates.** *Loading dose:* 10 mg/kg. I.V. infusion administered over 1 to 2 hr.

*Maintenance:* 7.5 mg/kg every 12 hr for 7 to 10 days. I.V. infusion administered over 1 to 2 hr. *Maximum:* 15 mg/kg daily.

- *To treat uncomplicated UTI*

### I.V. INFUSION, I.M. INJECTION

**Adults.** 250 mg twice daily for 7 to 10 days. I.V. infusion administered over 30 to 60 min.

***DOSAGE ADJUSTMENT (AMIKIN)*** For patients with impaired renal function, loading dose of 7.5 mg/kg daily; then

maintenance dosage based on creatinine clearance and serum creatinine level and given every 12 hr. For morbidly obese patients, dosage not to exceed 1.5 g daily.

- *To treat refractory Mycobacterium avium complex (MAC) lung disease for patients who did not achieve negative sputum cultures after a minimum of 6 consecutive months of a multidrug background regimen therapy*

## ORAL INHALATION (ARIKAYCE)

**Adults.** 590 mg once daily using the Lamira Nebulizer System.

Route	Onset	Peak	Duration
I.V.	Immediate	Unknown	Unknown
I.M.	Rapid	Unknown	Unknown

## Mechanism of Action

Binds to negatively charged sites on bacteria's outer cell membrane, disrupting cell integrity. Also binds to bacterial ribosomal subunits and inhibits protein synthesis. Both actions lead to cell death.

## Incompatibilities

Don't mix or infuse amikacin with other drugs.

## Contraindications

Hypersensitivity to amikacin, other aminoglycosides, or their components

# Interactions

## DRUGS

*general anesthetics*: Increased risk of neuromuscular blockade

*loop diuretics*: Increased risk of ototoxicity

*neuromuscular blockers*: Possibly increased neuromuscular blockade and prolonged respiratory depression

*penicillins*: Possibly inactivation of or synergistic effects with amikacin

*other nephrotoxic drugs*: Increased risk of nephrotoxicity

## Adverse Reactions

**CNS**: Drowsiness, headache, loss of balance, **neuromuscular blockade**, tremor, vertigo

**EENT**: Hearing loss, ototoxicity, tinnitus

**GI**: Nausea, vomiting

**GU**: **Azotemia**, dysuria, **nephrotoxicity**, oliguria or polyuria, proteinuria

**MS**: **Acute muscle paralysis**; arthralgia; muscle fatigue, spasms, and weakness

**RESP**: **Apnea**; *Inhalation form*: **bronchospasm**, exacerbation of underlying pulmonary disease, **hemoptysis**, **hypersensitivity pneumonitis**

**Other**: **Hyperkalemia**

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm such as total, irreversible, bilateral deafness in pediatric patients exposed in utero.
- Drug should not be given to pregnant women unless no other alternative is available.

## **LACTATION**

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential adverse reactions in the breastfed infant.

## **Nursing Considerations**

- Expect to obtain results of culture and sensitivity testing before therapy begins.
- Obtain patient's weight prior to treatment for calculation of correct dosage.
- Prepare amikacin I.V. solution by adding contents of 500-mg vial to 100 or 200 ml of sterile diluent. Then infuse drug over 30 to 60 minutes for adults and children and 1 to 2 hours for neonates.
- Give I.M. injection in large muscle mass.
- Know that Arikayce is for oral inhalation use only. Administer by nebulization only using the Lamira Nebulizer System. Prior to opening glass vial, shake vial well for at least 10 to 15 seconds until the contents appear uniform and well mixed. Open the vial by flipping up the plastic top of the vial then pulling downward to loosen the metal ring. The metal ring and rubber stopper should be removed carefully. Then pour the contents of the vial into the medication reservoir of the nebulizer handset.
- Know that patients with asthma, bronchospasm, chronic obstructive pulmonary disease, or known hyper-reactive airway disease may need to be pretreated with a short-acting selective beta-2 agonist. This is because the drug has been associated with an increased risk of respiratory adverse reactions such as bronchospasm, exacerbation of underlying pulmonary disease, hemoptysis and hypersensitivity pneumonitis.
- Watch for signs of ototoxicity, such as tinnitus and vertigo, especially during high-dosage or prolonged amikacin therapy.

**WARNING** Assess renal function before and daily during therapy, as ordered because amikacin may produce nephrotoxic effects. To minimize renal tubule irritation, maintain hydration during therapy.

- Be aware that amikacin may exacerbate muscle weakness in such conditions as myasthenia gravis and Parkinson's disease.
- Measure serum amikacin concentrations as ordered, usually 30 to 90 minutes after injection (for peak concentration) and just before administering next parenteral dose (for trough concentration).

## **PATIENT TEACHING**

- Tell patient that daily laboratory tests are necessary during treatment.
- Instruct patient to report ringing in ears, hearing changes, headache, nausea, vomiting, and changes in urination.
- Instruct patient prescribed oral inhalation amikacin therapy how to administer drug. Tell patient that drug is to be administered by nebulization only using the Lamira Nebulizer System. Prior to opening glass vial, instruct patient to shake vial well for at least 10 to 15 seconds until the contents appear uniform and well mixed. Then patient should open the vial by flipping up the plastic top of the vial then pulling downward to loosen the metal ring. The metal ring and rubber stopper should be removed carefully. Then tell patient to pour the contents of the vial into the medication reservoir of the nebulizer handset and then follow manufacturer instructions on use of the nebulizer unit.
- Tell patient using oral inhalation form that if he misses a daily dose, he should administer the next dose the next day and not double the dose.

**WARNING** Alert patient taking drug by oral inhalation to seek immediate medical attention if he experiences breathing difficulty.

# **amiloride hydrochloride**

# Apo Amiloride (CAN), Midamor

## Class and Category

*Pharmacologic class:* Potassium-sparing diuretic

*Therapeutic class:* Diuretic

## Indications and Dosages

- *As adjunct to loop or thiazide diuretic therapy in patient with heart failure or hypertension to correct diuretic-induced hypokalemia or to prevent diuretic-induced hypokalemia that increases the risk of arrhythmias or other complications*

## TABLETS

**Adults.** 5 to 10 mg daily as single dose; if hypokalemia persists, increased to 15 mg daily and then 20 mg daily.

Route	Onset	Peak	Duration
P.O.	2 hr	6-10 hr	24 hr

## Mechanism of Action

Inhibits sodium reabsorption in distal convoluted tubules and cortical collecting ducts, causing sodium and water loss and enhancing potassium retention.

## Contraindications

Hypersensitivity to amiloride or its components; impaired renal function; serum potassium level above 5.5 mEq/L;

therapy with another potassium-sparing diuretic, such as spironolactone or triamterene, or a potassium supplement

## Interactions

### DRUGS

*angiotensin-converting enzyme inhibitors, angiotensin II receptor antagonists, cyclosporine, enalapril, lisinopril, potassium products, spironolactone:* Increased risk of hyperkalemia

*digoxin:* Decreased effectiveness of digoxin

*lithium:* Reduced renal clearance of lithium and increased risk of lithium toxicity

*NSAIDs:* Reduced diuretic effect of amiloride

### FOODS

*high-potassium food:* Increased risk of hyperkalemia

## Adverse Reactions

**CNS:** Confusion, depression, dizziness, drowsiness, **encephalopathy**, fatigue, headache, insomnia, nervousness, paresthesia, somnolence, tremor, vertigo

**CV:** Angina, **arrhythmias**, orthostatic hypotension, palpitations

**EENT:** Dry mouth, increased intraocular pressure, nasal congestion, tinnitus, vision disturbances

**GI:** Abdominal pain or fullness, anorexia, appetite changes, constipation, diarrhea, **GI bleeding**, heartburn, indigestion, jaundice, nausea, thirst, vomiting

**GU:** Bladder spasms, dysuria, impotence, loss of libido, polyuria

**HEME:** Aplastic anemia, neutropenia

**MS:** Arthralgia, muscle spasms, or weakness

**RESP:** Cough, dyspnea

**SKIN:** Alopecia, pruritus, rash

**Other:** Dehydration, hyperchloremia, hyperkalemia, hypernatremia, metabolic acidosis

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential adverse reactions in the breastfed infant.

## Nursing Considerations

- Administer amiloride with food to reduce GI upset and early in the day to minimize sleep interference from polyuria.
- Monitor renal function test results, fluid intake and output, and weight. Also monitor serum potassium level to detect hyperkalemia.

**WARNING** Don't administer amiloride with other potassium-sparing diuretics.

### PATIENT TEACHING

- Warn patient to avoid high-potassium food and salt substitutes that contain potassium.
- Advise patient to consult prescriber before taking other drugs, including OTC remedies, especially sympathomimetics.
- Tell patient to report dizziness, trembling, numbness, and muscle weakness or spasms.
- Advise patient to increase fluid and fiber intake to prevent constipation.
- Warn patient to expect reversible hair loss and impotence.

## aminocaproic acid

**Amicar**

### Class and Category

*Pharmacologic class:* Aminohexanoic acid

*Therapeutic class:* Antifibrinolytic, antihemorrhagic

### Indications and Dosages

➤ *To treat excessive bleeding caused by fibrinolysis*

#### ORAL SOLUTION, SYRUP, TABLETS

**Adults.** *Initial:* 5 g in first hour, followed by 1 to 1.25 g/hr to sustain drug plasma level of 0.13 mg/ml. *Maximum:* 30 g daily.

#### I.V. INFUSION

**Adults.** 4 to 5 g in 250 ml of diluent over 1 hr followed by continuous infusion of 1 g/hr (4 ml/hr) in 50 ml of diluent.

Continued for 8 hr or until bleeding stops.

Route	Onset	Peak	Duration
P.O.	Rapid	Unknown	Unknown
I.V.	Immediate	Unknown	Under 3 hr

## Mechanism of Action

Inhibits breakdown of blood clots by interfering with plasminogen activator substances and producing antiplasmin activity.

## Contraindications

Active intravascular clotting such as in disseminated intravascular coagulation, hypersensitivity to aminocaproic acid or its components, upper urinary tract bleeding

## Interactions

### DRUGS

*activated prothrombin, prothrombin complex concentrates:* Increased risk of thrombosis

*estrogens, oral contraceptives:* Increased risk of hypercoagulation

## Adverse Reactions

**CNS:** CVA, delirium, dizziness, hallucinations, headache, malaise, weakness

**CV:** Bradycardia, cardiomyopathy, elevated serum CK level, hypotension, ischemia, thrombophlebitis

**EENT:** Nasal congestion, tinnitus

**GI:** Abdominal cramps and pain, diarrhea, elevated AST level, nausea, vomiting

**GU:** Elevated BUN level, **intrarenal obstruction**, **renal failure**

**HEME:** **Agranulocytosis**, **leukopenia**, **thrombocytopenia**

**MS:** Myopathy

**RESP:** Dyspnea, **pulmonary embolism**

**SKIN:** Pruritus, rash

**Other:** Elevated serum aldolase levels, **hyperkalemia**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that patients on oral therapy prescribed tablet form may need up to 10 tablets during the first hour of treatment and tablets around the clock during continued treatment.
- Mix aminocaproic acid solution for intravenous infusion with sterile water for injection, normal saline solution, D<sub>5</sub>W, or Ringer's solution.

**WARNING** Avoid rapid I.V. delivery because it increases risk of hypotension and bradycardia.

- Monitor neurologic status for drug-induced changes. Note that increased clotting may lead to stroke.

## PATIENT TEACHING

- Tell patient that he'll be closely monitored during I.V. therapy and will have blood drawn for laboratory tests before, during, and after treatment.
- Advise patient who takes aminocaproic acid at home to report adverse reactions, take drug exactly as prescribed, and keep follow-up appointments with prescriber.

# aminogluthimide

## Cytadren

## Class and Category

*Pharmacologic class:* Adrenal steroid inhibitor

*Therapeutic class:* Adrenal steroid inhibitor

## Indications and Dosages

- *To suppress adrenal function in patients with Cushing's syndrome who are waiting for surgery or for whom other treatment can't be used*

## TABLETS

**Adults.** *Initial:* 250 mg every 6 hr. Increased as needed by 250 mg daily every 1 to 2 wk. *Maximum:* 2,000 mg daily.

Route	Onset	Peak	Duration
P.O.	3-5 days	Unknown	72 hr

## Mechanism of Action

Inhibits the conversion of cholesterol to delta-5-pregnenolone, which is needed to produce certain hormones, including adrenal glucocorticoids, mineralocorticoids, estrogens, and androgens.

## Contraindications

Hypersensitivity to aminoglutethimide, glutethimide or their components

## Interactions

### DRUGS

*antidiabetics, dexamethasone, digoxin, medroxyprogesterone, synthetic glucocorticoids, theophylline, warfarin, and other oral anticoagulants:*  
Decreased effects of these drugs

## Adverse Reactions

**CNS:** Dizziness, drowsiness, fever, headache

**CV:** **Hypotension**, orthostatic hypotension, tachycardia

**ENDO:** Adrenal insufficiency, hypothyroidism, masculinization

**GI:** Anorexia, nausea

**SKIN:** Hair growth, morbilliform rash, pruritus, urticaria

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm.
- Drug should not be given during pregnancy unless situation is life-threatening.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential adverse reactions in the breastfed infant.

## Nursing Considerations

- Expect to reduce aminoglutethimide dosage or discontinue treatment if extreme drowsiness, severe rash, or excessively low cortisol level occurs.

**WARNING** Monitor for signs of hypo-thyroidism, including lethargy, dry skin, and slow pulse. If prescribed, administer thyroid hormone supplement.

- Monitor blood pressure for orthostatic or persistent hypotension.

### PATIENT TEACHING

- Teach patient to recognize orthostatic hypotension (dizziness, weakness when moving from sitting to standing position) and to minimize it by rising slowly from a supine to an upright position.

- Tell patient to report dizziness, appetite loss, nausea, headache, or severe drowsiness. Warn him to avoid driving if drowsy.
- Instruct patient to take a missed dose as soon as remembered and to space out the day's remaining doses evenly.
- Advise patient that rash, sometimes accompanied by fever, may appear on day 10 of treatment and should subside by day 15 or 16. Tell him to report severe rash or one that doesn't disappear.

## amiodarone hydrochloride

**Cordarone, Nexterone, Pacerone**

### Class and Category

*Pharmacologic class:* Benzofuran derivative

*Therapeutic class:* Class III antiarrhythmic

### Indications and Dosages

- *To treat life-threatening, recurrent ventricular fibrillation and hemodynamically unstable ventricular tachycardia when these arrhythmias don't respond to other drugs or when patient can't tolerate other drugs*

#### **TABLETS (PACERONE)**

**Adults.** *Loading:* 800 to 1,600 mg daily in divided doses for 1 to 3 wk. Once arrhythmia is controlled or side effects become prominent, dosage reduced to 600 to 800 mg daily in divided doses for 1 mo and then reduced to 400 mg daily if cardiac rhythm is stable. *Maintenance:* 400 mg daily.

- *To treat or prevent life-threatening, recurrent ventricular fibrillation and hemodynamically unstable ventricular tachycardia when these arrhythmias don't respond to other drugs, when patient can't tolerate other drugs, or when oral amiodarone is indicated but patient is unable to take oral medication*

## **I.V. INFUSION (CORDARONE)**

**Adults.** *Loading:* 150 mg over 10 min (15 mg/min) followed by 360 mg infused over 6 hr (1 mg/min). *Maintenance:* 540 mg infused over 18 hr (0.5 mg/min); then after the first 24 hr, 720 mg infused over 24 hr (0.5 mg/min), continued up to 2 to 3 wk, as needed. Rate may be increased in first 24 hr, if needed, but initial infusion rate should not exceed 30 mg/min. Changed to oral form as soon as possible.

## **I.V. INFUSION (NEXTERONE)**

**Adults.** *Loading:* 150 mg/100 ml premixed in dextrose over 10 min (15 mg/min) followed by 360 mg/200 ml premixed in dextrose infused over 6 hr (1 mg/min). *Maintenance:* 540 mg infused over 18 hr (0.5 mg/min) using 360 mg/200 ml premixed in dextrose; then after the first 24 hr, 720 mg infused over 24 hr (0.5 mg/min) using 360 mg/200 ml premixed in dextrose, continued up to 2 to 3 wk, as needed. Rate may be increased in first 24 hr, if needed, but initial infusion rate shouldn't exceed 30 mg/min. Changed to oral form as soon as possible.

- *To treat breakthrough episodes of ventricular fibrillation or hemo-dynamically unstable ventricular tachycardia*

## **I.V. INFUSION (NEXTERONE)**

**Adults.** 150 mg/100 ml premixed in dextrose and infused over 10 min (15 mg/min).

Route	Onset	Peak	Duration
P.O.	2 days-3 wk	1-5 mo	Weeks-months
I.V.	Hours-3 days	1-3 wk	Weeks-months

## Mechanism of Action

Acts on cardiac cell membranes, prolonging repolarization and the refractory period and raising ventricular fibrillation threshold. Drug relaxes vascular smooth muscles, mainly in coronary circulation, and improves myocardial blood flow. It relaxes peripheral vascular smooth muscles, decreasing peripheral vascular resistance and myocardial oxygen consumption.

## Incompatibilities

To prevent precipitation, don't mix amiodarone 4 mg/ml admixed with aminophylline, amoxicillin sodium-clavulanic acid, ampicillin sodium-sulbactam sodium, argatroban, bivalirudin, cefamandole nafate, cefazolin sodium, ceftazidime, digoxin, furosemide, mezlocillin sodium, heparin sodium, imipenem-cilastatin sodium sodium, magnesium sulfate, micafungin, piperacillin sodium-tazobactam sodium, potassium phosphates, sodium bicarbonate, sodium nitroprusside, and sodium phosphates. Also, don't use plastic containers in series connections because this could result in an air embolism and don't use evacuated glass containers for admixing Cordarone because precipitation may occur.

## Contraindications

Bradycardia that causes syncope (unless pacemaker present), cardiogenic shock, hypersensitivity to amiodarone or its components, SA node dysfunction, second- and third-degree AV block (unless pacemaker present)

## Interactions

### DRUGS

*anticoagulants*: Increased anticoagulant response and possibly serious bleeding

*azole antifungals, antiarrhythmics, fluoroquinolones (selected ones), loratadine, macrolide antibiotics (selected ones), trazodone*: Increased risk of prolonged QT interval and life-threatening arrhythmias such as torsades de points

*beta blockers*: Increased serum levels of beta blockers with increased risk of AV block, bradycardia, and hypotension

*calcium channel blockers*: Increased serum levels of these drugs and increased risk of AV block, bradycardia, and hypotension

*cholestyramine, phenytoin, rifampin, St. John's wort*: Decreased amiodarone level

*cimetidine, protease inhibitors (selected ones)*: Increased amiodarone level

*cyclosporine*: Increased cyclosporine level

*dabigatran, dextromethorphan, phenytoin*: Possible increased serum levels of these drugs

*dextromethorphan, methotrexate, phenytoin*: Increased serum levels of these drugs and increased risk of toxicity if amiodarone is taken orally for more than 2 weeks

*digoxin*: Increased serum digoxin level and risk of digitalis toxicity

*fentanyl*: Increased serum fentanyl level with increased risk of bradycardia, decreased cardiac output, and hypotension

*flecainide procainamide, quinidine*: Increased serum levels of these drugs

*HMG-CoA reductase inhibitors such as atorvastatin, lovastatin, and simvastatin*: Increased risk of myopathy and rhabdomyolysis

*ledipasvir/sofosbuvir, sofosbuvir/simeprevir*: May cause serious symptomatic bradycardia

*protease inhibitors*: Possibly increased risk of elevated amiodarone levels and toxicity

*rifampin, St. John's wort*: Decreased serum amiodarone level and effectiveness

*theophylline*: Increased serum theophylline level; increased risk of theophylline toxicity

## **FOODS**

*grapefruit juice*: Increased amiodarone level

## **Adverse Reactions**

**CNS**: Abnormal gait, ataxia, confusion, delirium, demyelinating polyneuropathy, disorientation, dizziness, fatigue, fever, hallucinations, headache, insomnia, involuntary motor activity, lack of coordination, malaise, paresthesia, parkinsonian symptoms, peripheral neuropathy, **pseudotumor cerebri**, sleep disturbances, tremor

**CV**: **Arrhythmias (including AV block, bradycardia, electromechanical dissociation, torsades de pointes, and ventricular tachycardia or fibrillation), cardiac arrest, cardiogenic shock**, edema, **heart failure, hypotension, QT prolongation**, vasculitis

**EENT**: Abnormal salivation, abnormal taste and smell, blurred vision, corneal microdeposits, dry eyes or mouth,

halo vision, lens opacities, macular degeneration, optic neuritis, optic neuropathy, papilledema, permanent blindness, photophobia, scotoma

**ENDO:** Hyperthyroidism, hypothyroidism, syndrome of inappropriate ADH secretion, thyroid nodules, **thyroid cancer**

**GI:** Abdominal pain, anorexia, **cirrhosis**, constipation, diarrhea, elevated bilirubin or liver enzymes, hepatic failure, hepatitis, nausea, **pancreatitis**, vomiting

**GU:** **Acute renal failure**, decreased libido, epididymitis, impotence, **renal insufficiency**

**HEME:** **Agranulocytosis, aplastic or hemolytic anemia, coagulation abnormalities, neutropenia, pancytopenia**, spontaneous bruising, **thrombocytopenia**

**MS:** Muscle weakness, myopathy, **rhabdomyolysis**

**RESP:** **Acute respiratory distress syndrome in postoperative setting**; bronchiolitis obliterans organizing pneumonia; bronchospasm; **eosinophilic pneumonia; infiltrates that lead to** dyspnea, cough, **hemoptysis, hypoxia, pulmonary fibrosis, pulmonary alveolar hemorrhage, pulmonary interstitial pneumonitis**; crackles and wheezing; pleural effusion; pleuritis; pneumonia; pulmonary inflammation, **pulmonary fibrosis; respiratory arrest or failure**

**SKIN:** Alopecia, bluish gray pigmentation, bullous dermatitis, eczema, **erythema multiforme, exfoliative dermatitis**, flushing, photosensitivity, pruritus, **skin cancer**, solar dermatitis, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis including shock, angioedema, drug reaction with eosinophilia and systemic**

**symptoms (DRESS),** lupus-like syndrome

## **Childbearing Considerations**

### **PREGNANCY**

- Drug crosses the placental barrier and has the possibility to cause fetal harm.
- Fetal adverse effects may include arrhythmias such as bradycardia, periodic ventricular extrasystoles, and QT prolongation; growth restriction; neurodevelopmental abnormalities, such as ataxia, delayed motor development, jerk nystagmus, and speech delay with difficulties with written language and math later in childhood; premature birth; and thyroid dysfunction, such as hyperthyroxinemia or hypothyroidism.
- Drug should not be given to pregnant women unless benefit to the mother outweighs potential risk to fetus.

### **LABOR & DELIVERY**

- Newborn should be monitored for signs and symptoms of cardiac arrhythmias and thyroid dysfunction.

### **LACTATION**

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

### **REPRODUCTION**

- Drug may reduce female and male fertility, but it is not known if this effect is reversible.
- Women of childbearing age should use effective contraception to avoid pregnancy.

## **Nursing Considerations**

- Check patient's implantable cardiac device (if present), as ordered, at the start of and during amiodarone therapy because drug may affect pacing or defibrillating thresholds.
- Dilute parenteral amiodarone in D<sub>5</sub>W or normal saline solution and mix in polyvinyl chloride (PVC), polyolefin, or glass containers except for Nexterone, which is already premixed.
- Use an in-line filter during I.V. administration of amiodarone. Also use a central venous catheter whenever possible. A central venous catheter is required when infusion rate exceeds 2 mg/ml because drug may cause peripheral vein phlebitis at higher rates. Amiodarone I.V. must be given by volumetric infusion pump.
- Monitor amiodarone I.V. infusion closely because loading doses at higher concentrations and rates may cause acute renal failure, hepatocellular necrosis, and death.
- Know that infusion of up to 0.5 mg/min may be continued for 2 to 3 weeks, regardless of patient's age, left ventricular function, or renal function.
- Expect patient to be switched to oral therapy from intravenous therapy as soon as possible with dosage dependent on the dose of intravenous drug already administered. Monitor all patients but especially elderly patients closely when conversion to oral amiodarone is made for continued effectiveness.

**WARNING** Be aware that amiodarone may cause or worsen pulmonary disorders that may develop days to weeks after therapy and progress to respiratory failure or even death. Expect to obtain chest x-ray and pulmonary function tests before therapy starts and then chest x-ray and follow-up exams every 3 to 6 months during therapy.

- Monitor vital signs and oxygen level often during and after giving amiodarone. Keep emergency equipment and drugs nearby.

**WARNING** Monitor continuous ECG; check for increased PR and QRS intervals, arrhythmias, and heart rate below 60 beats/min because amiodarone may cause sinus arrest or symptomatic bradycardia and new ventricular

arrhythmias or worsen existing arrhythmias as well as increasing resistance to cardioversion. Electrolyte imbalance or use of concomitant antiarrhythmics or other interacting drugs may increase the development of these arrhythmias. Expect to correct electrolyte imbalance, as ordered, prior to initiating treatment with amiodarone.

- Monitor serum amiodarone level, which normally ranges from 1.0 to 2.5 mcg/ml.
- Assess thyroid hormone levels; drug inhibits conversion of  $T_4$  to  $T_3$  and may cause drug-induced hyperthyroidism, thyrotoxicosis, and new or worsened arrhythmias. If new signs of arrhythmia occur, notify prescriber at once.
- Monitor liver enzymes, as ordered. If elevations become persistent and significant, notify prescriber and expect maintenance dosage to be reduced or drug discontinued.
- Be aware that patient should undergo regular ophthalmic examinations including funduscopy and slit-lamp examination during amiodarone therapy because drug can cause serious visual impairment including permanent blindness.

## **PATIENT TEACHING**

- Instruct patient to take oral drug consistently with regard to meals.
- Explain that patient will need frequent monitoring and laboratory tests during treatment.
- Advise patient to report cough, dark urine, dyspnea, fainting, fatigue, light-headedness, nausea, swollen feet and hands, vomiting, wheezing, yellow sclerae or skin, or a sudden change in quality or rapidity of pulse.
- Instruct patient to report abnormal bleeding or bruising. Also tell patient to report any sign of visual impairment or decreased or increased levels of energy.
- Stress importance of informing all prescribers of amiodarone use, as serious drug interactions may occur.
- Advise patient to avoid corneal refractive laser surgery while taking drug.

- Warn female patient of childbearing age that amiodarone can cause fetal harm. Instruct her to use effective contraceptive measures and report suspected or known pregnancy immediately.
- Advise female patient who has been breastfeeding to discontinue nursing, because drug is excreted in human milk and may cause potential harm.
- Advise patient to avoid drinking grapefruit juice or taking St. John's Wort while receiving amiodarone.

## amitriptyline hydrochloride

**Elavil (CAN), Levate (CAN)**

### Class and Category

*Pharmacologic class:* Tricyclic antidepressant

*Therapeutic class:* Antidepressant

### Indications and Dosages

- *To relieve depression, especially when accompanied by anxiety and insomnia*

#### **TABLETS**

**Adults.** *Out-patient:* 75 mg daily in divided doses, increased to 150 mg daily, if needed. Increases made preferably with late afternoon and/or bedtime doses. Alternatively, 50 to 100 mg at bedtime, increased by 25 to 50 mg, as needed, in bedtime dose to 150 mg daily. *In-patient:* 100 mg daily, gradually increased to 300 mg daily, if needed. *Maintenance:* 40 to 100 mg daily at bedtime.

**DOSAGE ADJUSTMENT** Dosage reduced to 10 mg three times a day plus 20 mg at bedtime for adolescent and elderly patients.

Route	Onset	Peak	Duration
P.O.	14-21 days	Unknown	Unknown

## Contraindications

Acute recovery phase after MI, concurrent therapy with cisapride, hypersensitivity to amitriptyline or its components, MAO inhibitor therapy within 14 days

## Interactions

### DRUGS

*anticholinergics, epinephrine, norepinephrine:* Increased effects of these drugs

*barbiturates:* Decreased amitriptyline level

*carbamazepine:* Decreased serum amitriptyline level and increased serum carbamazepine level, which increases therapeutic and toxic effects of carbamazepine

*cimetidine, disulfiram, fluoxetine, fluvoxamine, haloperidol, H<sub>2</sub>-receptor antagonists, methylphenidate, oral*

*contraceptives, paroxetine, phenothiazines, sertraline:* Increased serum amitriptyline level

*cisapride:* Possibly prolonged QT interval and increased risk of arrhythmias

*clonidine, guanethidine, and other antihypertensives:* Decreased antihypertensive effects

*dicumarol:* Increased anticoagulant effect

*levodopa:* Decreased levodopa absorption; sympathetic hyperactivity, sinus tachycardia, hypertension, agitation

*MAO inhibitors:* Possibly seizures and death

*thyroid replacement drugs:* Arrhythmias and increased antidepressant effects

## ACTIVITIES

*alcohol use:* Enhanced CNS depression

*smoking:* Decreased amitriptyline effects

## Adverse Reactions

**CNS:** Anxiety, ataxia, **coma**, chills, delusions, disorientation, drowsiness, extrapyramidal reactions, fatigue, fever, headache, insomnia, nightmares, peripheral neuropathy, **suicidal ideation**, tremor

**CV:** **Arrhythmias (including prolonged AV conduction, heart block**, and tachycardia), **cardiomyopathy**, hypertension, **MI**, nonspecific ECG changes, orthostatic hypotension, palpitations

**EENT:** Abnormal taste, black tongue, blurred vision, dry mouth, increased salivation, nasal congestion, tinnitus

**ENDO:** Gynecomastia, **hyperglycemia**, **hypoglycemia**, increased prolactin level, syndrome of inappropriate ADH secretion

**GI:** Abdominal cramps, constipation, diarrhea, flatulence, ileus, increased appetite, nausea, vomiting

**GU:** Impotence, libido changes, menstrual irregularities, testicular swelling, urinary hesitancy, urine retention

**HEME:** **Agranulocytosis**, **bone marrow depression**, eosinophilia, **leukopenia**, **thrombocytopenia**

**SKIN:** Alopecia, flushing, purpura

**Other:** Weight gain

---

## Mechanism of Action

Normally, when an impulse reaches adrenergic nerves, the nerves release serotonin and norepinephrine from their storage sites. Most of this is taken back into the nerves and stored by the reuptake mechanism, as shown below on the left.

Amitriptyline blocks serotonin and norepinephrine reuptake by adrenergic nerves. By doing so, it raises serotonin and norepinephrine levels at nerve synapses. This action may elevate mood and reduce depression.

Description

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm but limited studies suggest it may.
- Know that drug is a tricyclic antidepressant. This type of antidepressant has been known to cause withdrawal symptoms such as agitation and

respiratory depression in the neonate when given to the mother during the last trimester of pregnancy. Also, urinary retention in the neonate has been reported when mother has taken drug during pregnancy.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential adverse reactions in the breastfed infant

## Nursing Considerations

- Use caution if patient has a history of seizures, urine retention, or angle-closure glaucoma because of amitriptyline's atropine-like effects.

**WARNING** Don't give an MAO inhibitor within 14 days of amitriptyline because of the risk of seizures and death.

- Closely monitor patient with CV disorder because amitriptyline may cause arrhythmias, such as sinus tachycardia.
- Watch patients closely (especially adolescents and young adults), for suicidal tendencies, particularly when therapy starts and dosage changes. Depression may worsen temporarily during these times.
- Monitor blood pressure for hypotension or hypertension.
- Stay alert for behavior changes, such as hallucinations and decreased interest in personal appearance. Be aware that psychosis may develop in schizophrenic patients, and symptoms may increase in paranoid patients.
- Avoid abrupt withdrawal after long use because nausea, headache, vertigo, and nightmares may occur.

## PATIENT TEACHING

- Instruct patient to avoid using alcohol or OTC drugs that contain alcohol during amitriptyline therapy because alcohol enhances CNS depressant

effects.

- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a teenager or young adult.

## amlodipine benzoate

**Katerzia**

## amlodipine besylate

**Norvasc**

### Class and Category

*Pharmacologic class:* Calcium channel blocker

*Therapeutic class:* Antianginal, antihypertensive

### Indications and Dosages

➤ *To control hypertension*

#### ORAL SUSPENSION, TABLETS

**Adults.** *Initial:* 5 mg daily, increased gradually over 10 to 14 days, as needed. *Maximum:* 10 mg daily.

**Children age 6 to 17 years.** 2.5 to 5 mg once daily.  
Maximum: 5 mg once daily.

***DOSAGE ADJUSTMENT*** Initially 2.5 mg daily for elderly, fragile, or small patients or patients with impaired hepatic function. Increased gradually over 7 to 14 days based on response.

- *To treat chronic stable angina and vasospastic angina (Prinzmetal's or Variant angina); to treat angiographically documented coronary artery disease (CAD) in patients without heart failure or an ejection fraction less than 40%*

## ORAL SUSPENSION, TABLETS

**Adults.** 5 to 10 mg daily.

***DOSAGE ADJUSTMENT*** 2.5 to 5 mg daily for elderly patients and those with impaired hepatic function.

Route	Onset	Peak	Duration
P.O.	Unknown	6–12 hr	24 hr

## Mechanism of Action

Binds to dihydropyridine and nondihydropyridine cell membrane receptor sites on myocardial and vascular smooth-muscle cells and inhibits influx of extracellular calcium ions across slow calcium channels. This decreases intracellular calcium level, inhibiting smooth-muscle cell contractions and relaxing coronary and vascular smooth muscles, decreasing peripheral vascular resistance, and reducing systolic and diastolic blood pressure. Decreased peripheral vascular resistance also decreases myocardial workload, oxygen demand, and possibly angina. Also, by inhibiting coronary artery muscle cell contractions and restoring blood flow, drug may relieve Prinzmetal's angina.

## Contraindications

Hypersensitivity to amlodipine or its components

# Interactions

## DRUGS

*ACE inhibitors, aliskiren (in patients with diabetes or renal impairment):* Increased risk of hyperkalemia, hypotension, and renal dysfunction

*cyclosporine, simvastatin, tacrolimus:* Possibly increased blood levels of these drugs

*CYP3A4 inhibitors such as diltiazem, ketoconazole, itraconazole, and ritonavir:* Possibly increased blood amlodipine level

*sildenafil:* Possibly excessive hypotension

## Adverse Reactions

**CNS:** Anxiety, dizziness, extrapyramidal disorder, fatigue, headache, lethargy, light-headedness, paresthesia, somnolence, syncope, tremor

**CV:** **Arrhythmias**, chest pain, **hypotension**, palpitations, peripheral edema

**EENT:** Dry mouth, gingival hyperplasia, pharyngitis

**ENDO:** Hot flashes

**GI:** Abdominal cramps or pain, anorexia, constipation, diarrhea, dysphagia, elevated liver enzymes, esophagitis, flatulence, indigestion, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Decreased libido, impotence, urinary frequency

**MS:** Myalgia

**RESP:** Dyspnea

**SKIN:** Dermatitis, flushing, rash

**Other:** Weight loss

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Use amlodipine cautiously in patients with heart block, heart failure, impaired renal function, hepatic disorder, or severe aortic stenosis.
- Monitor patient with impaired hepatic function closely because amlodipine is extensively metabolized by the liver, and expect to titrate dosage slowly when administering drug to patients with severe hepatic impairment.
- Monitor blood pressure while adjusting dosage, especially in patients with heart failure or severe aortic stenosis because symptomatic hypotension may occur.
- Assess patient frequently for chest pain when starting or increasing the dose of amlodipine, because worsening of angina or an acute myocardial infarction can occur, especially in patients with severe obstructive coronary artery disease.

### **PATIENT TEACHING**

- Tell patient to take missed dose as soon as remembered and next dose in 24 hours.

- Tell patient to immediately notify prescriber of dizziness, arm or leg swelling, difficulty breathing, hives, or rash.
- Suggest taking amlodipine with food to reduce GI upset.
- Advise patient to have blood pressure checked routinely for possible hypotension.
- Tell mothers interested in breastfeeding to discuss with prescriber, because amlodipine is present in human milk.

## amoxicillin trihydrate

(amoxycillin)

**Amoxil, Apo-Amoxi (CAN), Larotid, Moxatag, Novamoxin (CAN)**

### Class and Category

*Pharmacologic class:* Aminopenicillin

*Therapeutic class:* Antibiotic

### Indications and Dosages

- *To treat ear, nose, throat, GU tract, skin, and soft-tissue infections*

#### **CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults and children weighing 40 kg (88 lb) or more.**

250 mg every 8 hr; for severe infections, 500 mg or 875 mg every 12 hr.

**Children age 12 wk and over weighing less than 40 kg.** 20 mg/kg daily in divided doses every 8 hr; for severe infections, 40 to 45 mg/kg/day in divided doses every 12 hr.

**Children under age 12 wk.** Up to 30 mg/kg/day in divided doses every 12 hr.

- *To treat tonsillitis or pharyngitis caused by Streptococcus pyogenes*

## **E.R. TABLETS (MOXATAG)**

**Adults and children age 12 and over.** 775 mg once daily for 10 days, taken within 1 hr of finishing a meal.

- *To treat lower respiratory tract infections*

## **CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults and children weighing 40 kg (88 lb) or more.** 875 mg every 12 hr; for severe infections, 500 mg every 8 hr.

**Children age 12 wk and over weighing less than 40 kg.** 40 mg/kg in divided doses every 8 hr or 45 mg/kg in divided doses every 12 hr.

**Children under age 12 wk.** Up to 30 mg/kg daily in divided doses every 12 hr.

- *As adjunct to eradicate Helicobacter pylori to reduce risk of duodenal ulcer recurrence*

## **CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults.** 1 g every 12 hr with 500 mg of clarithromycin every 12 hr and 30 mg of lansoprazole every 12 hr for 14 days, or 1 g every 8 hr with 30 mg of lansoprazole every 8 hr for 14 days.

- *To prevent bacterial endocarditis before dental, oral, or upper respiratory tract procedures*

## **CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults and children weighing 40 kg (88 lb) or more.** 2 g 1 hr before procedure.

**Children weighing less than 40 kg.** 50 mg/kg 1 hr before procedure.

***DOSAGE ADJUSTMENT*** For patients with impaired renal function with a glomerular filtration rate less than 30 ml/min, dosage reduced to less than 875 mg; for a glomerular filtration rate of 10 to 30 ml/min dosage reduced to 500 mg or 250 mg every 12 hr; for a glomerular filtration rate less than 10 ml/min dosage reduced to 500 mg or 250 mg and frequency reduced to every 24 hr.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	6–8 hr

## **Mechanism of Action**

Kills bacteria by binding to and inactivating penicillin-binding proteins on the inner bacterial cell wall, weakening the bacterial cell wall and causing lysis.

## **Contraindications**

Hypersensitivity including severe reactions (anaphylaxis or Stevens–Johnson syndrome) to amoxicillin, other beta-lactam antibiotics, or their components

## **Interactions**

## DRUGS

*allopurinol*: Increased risk of rash

*chloramphenicol, erythromycins, sulfonamides,*

*tetracyclines*: Reduced bactericidal effect of amoxicillin

*methotrexate*: Increased risk of methotrexate toxicity

*oral anticoagulants*: Possible prolonged prothrombin time (increased international normalized ratio)

*oral contraceptives with estrogen*: Possibly reduced effectiveness of contraceptive

*probenecid*: Increased amoxicillin effects

## Adverse Reactions

**CNS**: Agitation, anxiety, behavior changes, confusion, dizziness, insomnia, reversible hyperactivity, **seizures**

**CV**: Hypersensitivity vasculitis

**EENT**: Black, hairy tongue; mucocutaneous candidiasis; tooth discoloration

**GI**: ***Clostridium difficile***-associated diarrhea, diarrhea, elevated liver enzymes, **hemorrhagic or pseudomembranous colitis, hepatic dysfunction, jaundice, nausea, vomiting**

**GU**: Crystalluria, vaginal mycosis

**HEME**: **Agranulocytosis**, anemia (including **hemolytic anemia**), eosinophilia, granulocytosis, **leukopenia, thrombocytopenia, thrombocytopenic purpura**

**SKIN**: **Erythema multiforme**, erythematous maculopapular rash, generalized exanthematous pustulosis, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria

**Other:** Allergic reactions, anaphylaxis, serum sickness-like reaction (such as arthralgia, arthritis, fever, myalgia, rash, and urticaria)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- It is not known if drug given to mother during labor has immediate or delayed adverse effects on the fetus.

### LACTATION

- Drug is present in breast milk and may lead to sensitization in infant.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that patients with mononucleosis shouldn't receive amoxicillin because this class of drugs may cause an erythematous rash.
- Use drug cautiously in patients with hepatic impairment. Monitor hepatic and renal function and CBC, as ordered, in patients on prolonged therapy. Also use cautiously in breastfeeding and elderly patients.
- Expect to start therapy before culture and sensitivity test results are known.
- Be aware that chewable tablets and tablets for oral suspension contain phenylalanine.

**WARNING** Stop amoxicillin immediately and provide emergency care as indicated and ordered if an allergic reaction occurs.

- Monitor patient closely for diarrhea, which may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber, expect to withhold amoxicillin, and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- Expect treatment that lasts at least 10 days for hemolytic streptococcal infections.
- Monitor patient for superinfection. If it occurs, expect to discontinue drug and provide treatment as ordered.

## **PATIENT TEACHING**

- Tell patient to refrigerate reconstituted suspension and to shake well before each use.
- Know that when amoxicillin suspension is prescribed for a child, instruct parents to place it directly on child's tongue to swallow. If this does not work, tell parents to mix dose of suspension with formula or cold drink (milk, fruit juice, ginger ale, water) and have child drink it immediately.
- Tell patient to chew or crush chewable tablets and not to swallow them whole.
- Urge patient to take amoxicillin for full length of time prescribed, even if he feels better.
- Teach patient to report adverse reactions and notify prescriber if infection worsens or doesn't improve after 72 hours.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and may be serious, requiring prompt treatment.
- Inform patient with diabetes who is using glucose tests based on the Benedict's copper reduction reaction that false-positive reactions may occur when testing for glucose in urine. Advise patient to use glucose tests based on enzymatic glucose oxidase reaction instead.

# amphetamine

**Adzenys ER, Adzenys XR-ODT,  
Dyanavel XR**

# amphetamine sulfate

# dextroamphetamine sulfate

**Dexedrine ER, Liquadd, ProCentra,  
Zenzedi**

## Class and Category

*Pharmacologic class:* Phenethylamine

*Therapeutic class:* CNS stimulant

*Controlled substance schedule:* II

## Indications and Dosages

- *To treat attention deficit hyperactivity disorder (ADHD)*

### **ORAL SOLUTION (LIQUADD, PROCENTRA), TABLETS (ZENZEDI)**

**Children age 6 and over.** *Initial:* 5 mg daily or twice daily. Increased by 5 mg daily at 1-wk intervals until desired response occurs.

**Children ages 3 to 6.** *Initial:* 2.5 mg daily. Increased by 2.5 mg daily at 1-wk intervals until desired response

occurs.

## **ER CAPSULES (DEXEDRINE ER)**

**Children age 6 and over.** *Initial:* 5 mg daily or twice daily. Increased by 5 mg daily at 1-wk intervals until desired response occurs.

## **ER ORAL SOLUTION (DYANAVAL XR)**

**Children age 6 and over.** *Initial:* 2.5 or 5 mg once daily in the morning. Increased by 2.5 to 10 mg every 4 to 7 days. *Maximum:* 20 mg daily.

## **ER ORALLY DISINTEGRATING TABLETS (ADZENYS XR-ODT), ER ORAL SUSPENSION (ADZENYS ER)**

*Adults.* 12.5 mg daily.

**Children age 6 and over.** *Initial:* 6.3 mg once daily in the morning. Increased by 3.1 or 6.3 mg at weekly intervals. *Maximum:* 18.8 mg daily (children 6 to 12 years); 12.5 mg daily (children 13 to 17 years).

➤ *To treat narcolepsy*

## **ER CAPSULES (DEXEDRINE ER), ORAL SOLUTION (LIQUADD, PROCENTRA), TABLETS (ZENZEDI)**

**Adults.** 5 to 60 mg daily in divided doses, depending on response.

**Children age 12 and over.** *Initial:* 10 mg daily. Increased by 10 mg daily at 1-wk intervals until desired response occurs.

**Children ages 6 to 12.** *Initial:* 5 mg daily. Increased by 5 mg daily at 1-wk intervals until desired response occurs.

## Mechanism of Action

May produce its CNS stimulant effects by facilitating release and blocking reuptake of norepinephrine at adrenergic nerve terminals and by direct stimulation of alpha and beta receptors in the peripheral nervous system. It also releases and blocks reuptake of dopamine in limbic regions of the brain. The drug's main action appears to be in the cerebral cortex and, possibly, the reticular activating system. These actions cause decreased motor restlessness, increased alertness, and diminished drowsiness and fatigue. Its peripheral actions include increased blood pressure and mild bronchodilation and respiratory stimulation.

## Contraindications

Advanced arteriosclerosis, agitation (for narcolepsy treatment), glaucoma, history of drug abuse, hypersensitivity or idiosyncratic reaction to sympathomimetic amines, hyperthyroidism, MAO inhibitor therapy including I.V. methylene blue or linezolid within 14 days, moderate to severe hypertension, symptomatic cardiovascular disease

## Interactions

### DRUGS

*acetazolamide, alkalinizers (such as sodium bicarbonate), some thiazides*: Increased blood level and effects of amphetamine  
*adrenergic blockers*: Inhibited adrenergic blockade  
*antihistamines*: Possibly reduced sedation from antihistamine

*antihypertensives*: Possibly decreased antihypertensive effects

*buspirone, CYP 206 inhibitors, fentanyl, lithium, MAO inhibitors, selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors, St. John's wort, tramadol, tricyclic antidepressants, triptans*:

Increased risk of serotonin syndrome

*chlorpromazine*: Inhibited CNS stimulant effects of amphetamine

*ethosuximide*: Possibly delayed ethosuximide absorption

*GI acidifiers (such as ascorbic acid), reserpine*: Decreased amphetamine absorption

*guanethidine*: Decreased antihypertensive effect and decreased amphetamine absorption

*haloperidol*: Decreased CNS stimulation

*lithium carbonate*: Possibly decreased anorectic and stimulant effects of amphetamine

*MAO inhibitors*: Potentiated effects of amphetamine; possibly hypertensive crisis

*meperidine*: Increased analgesia

*methenamine*: Increased urine excretion and decreased effects of amphetamine

*norepinephrine*: Possibly increased adrenergic effect of norepinephrine

*phenobarbital, phenytoin*: Synergistic anticonvulsant action

*propoxyphene*: Increased CNS stimulation, potentially fatal seizures

*proton pump inhibitors*: Possibly decreased effectiveness of amphetamines

*tricyclic antidepressants*: Possibly enhanced antidepressant effects and decreased effects of amphetamine

*urinary acidifiers (such as ammonium chloride and sodium acid phosphate)*: Increased amphetamine excretion and decreased amphetamine blood level and effects

*veratrum alkaloids*: Decreased hypotensive effect

## FOODS

*acidic fruit juices:* Decreased amphetamine absorption

## Adverse Reactions

**CNS:** Aggression, anger, anxiety, depression, dizziness, dyskinesia, dysphoria, euphoria, exacerbation of motor and phonic tics and Tourette's syndrome, excessive skin picking or talkativeness, hallucinations, headache, insomnia, irritability, overstimulation, paranoia, paresthesia, psychotic episodes, restlessness, **serotonin syndrome**, tremor

**CV:** **Cardiomyopathy**, hypertension, **MI**, palpitations, Raynaud's phenomenon, tachycardia

**EENT:** Blurred vision, dry mouth, mydriasis, teeth grinding, unpleasant taste

**ENDO:** Growth suppression in children and teens (long-term use)

**GI:** Anorexia, constipation, diarrhea

**GU:** Frequent or prolonged erections, impotence, libido changes

**MS:** **Rhabdomyolysis**

**SKIN:** Alopecia, excessive skin picking, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, weight loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-961-2388 or <https://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/othermedications/>.
- It is not known if drug may cause fetal harm but it can cause neonatal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LABOR & DELIVERY

- Know that infants born to mothers dependent on amphetamines have an increased risk of premature delivery and low birth weight.
- Infants born to mothers dependent on amphetamines may also experience withdrawal symptoms such as agitation and significant lassitude in the postnatal period.

## LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential adverse reactions in the breastfed infant.

## Nursing Considerations

- Keep in mind that when symptoms of ADHD occur with acute stress reactions, treatment with amphetamines usually isn't indicated.

**WARNING** Don't give amphetamine during or for up to 14 days after MAO therapy to prevent hypertensive crisis.

- Be aware that 5 ml of oral solution contains 5 mg of dexamphetamine.
- Expect to decrease dosage if patient has bothersome adverse reactions, such as insomnia and anorexia. To minimize insomnia, administer drug earlier in day.
- Be alert for evidence of long-term amphetamine abuse, such as hyperactivity, irritability, marked insomnia, personality changes, and

severe dermatoses. If patient suddenly stops drug after long-term, high-dose regimen, watch for extreme fatigue and depression.

**WARNING** Monitor patient closely for evidence of serotonin syndrome, such as agitation, coma, diarrhea, hallucinations, hyperreflexia, hyperthermia, incoordination, labile blood pressure, nausea, tachycardia, and vomiting. Notify prescriber immediately because serotonin syndrome reactions may be life-threatening. Expect to discontinue amphetamine therapy and any other serotonergic agents patient may be taking. Be prepared to provide supportive care.

- Monitor children and teens receiving drug long term for growth suppression or not gaining weight.

## **PATIENT TEACHING**

- Instruct breastfeeding patient to avoid breastfeeding during amphetamine therapy because drug is excreted in breast milk.
- Advise women of childbearing age to notify prescriber if pregnancy occurs.
- Teach patient to take first dose on awakening and subsequent doses as prescribed. Tell him not to take last dose late in evening because insomnia may occur.
- Inform patient or caregiver that each 5 ml of oral solution contains 5 mg of dexamphetamine. Advise patient to use a calibrated measuring device for accurate dose.
- Instruct patient prescribed orally disintegrating tablets how to remove tablets from package and to avoid pushing tablets through the foil. Tablet should be immediately placed on the tongue and allowed to dissolve without chewing or crushing.
- Urge patient to avoid hazardous activities until drug's effects are known.
- Advise patient not to take amphetamine with acidic fruit juice because doing so decreases drug absorption.

- Explain drug's abuse potential, and caution against altering dosage unless prescribed.
- Instruct patient to notify prescriber before taking any new drugs, including over-the-counter preparations.
- Tell patient to report any new or worsening behavior and thought problems; new or worsening bipolar illness; new manic symptoms; or new psychotic symptoms such as believing things that are not true, feeling suspicious, or hearing voices.

## amphotericin B

### **Fungizone Intravenous**

## amphotericin B lipid complex

### **Abelcet**

## amphotericin B liposomal complex

### **AmBisome**

## **Class and Category**

*Pharmacologic class:* Amphoteric polyene

*Therapeutic class:* Antifungal

## **Indications and Dosages**

- *To treat severe fungal infections*

## **I.V. INFUSION (FUNGIZONE)**

**Adults and adolescents.** *Initial:* 1-mg test dose in 20 ml of D<sub>5</sub>W infused over 20 to 30 min; if test dose is tolerated, then 0.25 to 0.3 mg/kg daily prepared as a 0.1 mg/ml infusion, given over 2 to 6 hr. Increased in 5- to 10-mg increments, based on patient tolerance and infection severity, to a final daily dose of 0.5 to 0.7 mg/kg but not to exceed a total daily dose of 1.5 mg/kg.

*Usual range:* Up to 1 mg/kg daily or 1.5 mg/kg every other day.

- *To provide empirical therapy for presumed fungal infection in febrile, neutropenic patients*

## **I.V. INFUSION (AMBISOME)**

Adults and children. 3 mg/kg daily infused over 2 hr. Infusion time may be decreased to 1 hr if tolerated or increased if patient experiences discomfort.

- *To treat oral candidiasis*

## **ORAL SUSPENSION (AMPHOTERICIN B)**

**Adults and children.** 1 ml (100 mg) four times daily for 14 days.

- *To treat invasive amphotericin B-resistant fungal infections*

## **I.V. INFUSION (ABELCET)**

**Adults and children.** 5 mg/kg daily infused at 2.5 mg/kg/hr.

- *To treat severe aspergillosis, candidiasis, or cryptococcosis refractory to amphotericin B*

*deoxycholate or contraindicated*

## **I.V. INFUSION (AMBISOME)**

**Adults and children.** 3 to 5 mg/kg daily infused over 2 hr. Infusion time may be decreased to 1 hr if tolerated or increased if patient experiences discomfort.

➤ *To treat visceral leishmaniasis*

## **I.V. INFUSION (AMBISOME)**

**Immunocompetent adults and children.** 3 mg/kg daily on days 1 through 5 and on days 14 and 21, infused over 2 hr. Infusion time may be decreased to 1 hr if tolerated or increased if patient has discomfort.

**Immunocompromised adults and children.** 4 mg/kg daily on days 1 through 5 and days 10, 17, 24, 31, and 38 infused over 2 hr. Infusion time may be decreased to 1 hr if tolerated or increased if patient has discomfort.

➤ *To treat cryptococcal meningitis in patients with HIV*

## **I.V. INFUSION (AMBISOME)**

**Adults and children.** 6 mg/kg daily infused over 2 hr. Infusion time may be decreased to 1 hr if tolerated or increased if patient has discomfort.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.	Unknown	Unknown	Unknown
I.V.	Immediate	Unknown	Unknown

## **Mechanism of Action**

Binds to sterols in fungal cell plasma membranes, which changes membrane permeability and allows loss of

potassium and small molecules from cells. This action results in fungal cell impairment or death.

## Incompatibilities

Don't reconstitute amphotericin B with diluents other than those recommended because solutions with sodium chloride or bacteriostatic agents (such as benzyl alcohol) may cause drug precipitation.

## Contraindications

Hypersensitivity to amphotericin B or its components

## Interactions

### DRUGS

*antineoplastics*: Increased risk of bronchospasm, hypotension, and nephrotoxicity

*corticosteroids, corticotropin*: Increased risk of hypokalemia and cardiac dysfunction

*cyclosporine, nephrotoxic drugs*: Increased risk of nephrotoxicity

*digitalis glycosides*: Possibly hypokalemia and more severe digitalis toxicity

*flucytosine*: Possibly increased flucytosine toxicity

*imidazoles such as cloyrimazole, fluconazole, ketoconazole,*

*miconazole*: Possibly induced resistance to amphotericin

*leukocyte transfusion*: Possibly acute pulmonary toxicity

*skeletal muscle relaxants*: Possibly hypo-kalemia and increased muscle relaxation

## Adverse Reactions

**CNS:** Fever, headache, shaking chills, tiredness, weakness

**CV:** Chest pain, **hypotension**, irregular heartbeat

**EENT:** Difficulty swallowing, pharyngitis

**GI:** Abdominal pain, anorexia, diarrhea, **hepatic failure**, indigestion, jaundice, nausea, vomiting

**GU:** Decreased or increased urine output, hemorrhagic cystitis, impaired renal function

**HEME:** **Agranulocytosis**, anemia, **leukopenia**, **thrombocytopenia**, **unusual bleeding** or bruising

**MS:** Arthralgia, muscle spasms, myalgia, **rhabdomyolysis**

**RESP:** **Apnea**, **bronchospasm**, **cyanosis**, dyspnea, **hypoventilation**, **hypoxia**, **pulmonary edema**, tachypnea

**SKIN:** Erythema, flushing, maculopapular rash, pruritus and redness especially around ears, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **hypocalcemia**, **hypokalemia**, **hypomagnesemia**, infusion-site pain, and thrombophlebitis

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding should be discontinued during drug therapy.

# Nursing Considerations

- Prepare amphotericin B by adding 10 ml of sterile water for injection without a bacteriostatic agent to vial containing 50 mg of amphotericin B. For I.V. infusion, dilute solution containing 5 mg/ml to 0.1 mg/ml by adding 1 ml (5 mg) of solution to 49 ml of D<sub>5</sub>W with a pH above 4.2.
- Know that before using D<sub>5</sub>W to dilute amphotericin B solution, determine the injection's pH aseptically. If pH is below 4.2, follow manufacturer's instructions for buffering it.
- Avoid using in-line membrane filter or use one with a mean pore diameter of more than 1 micron to prevent significant drug removal because reconstituted amphotericin B is a colloidal suspension.
- Prepare amphotericin B cholesteryl sulfate complex by reconstituting with sterile water for injection. Using a sterile syringe and 20G needle, rapidly add 10- or 20-ml sterile water for injection to a 50- or 100-mg vial, respectively, to obtain a solution containing 5 mg of amphotericin B per milliliter. Shake gently by hand, rotating vial until solids are dissolved; fluid may be clear or opalescent. For infusion, further dilute reconstituted solution to about 0.6 mg/ml. Don't filter solution or use an in-line filter. Flush existing line with D<sub>5</sub>W or use a separate line.
- Prepare amphotericin B lipid complex by shaking vial gently until no yellow sediment is seen. Using an 18G needle, withdraw prescribed dose from required number of vials into one or more 20-ml syringes. Replace needle with 5-micron filter needle supplied with each vial. Empty syringe contents into bag of D<sub>5</sub>W so that final concentration is 1 mg/ml. Expect to use a concentration of 2 mg/ml for children and patients with cardiovascular disease. Before infusion, shake bag until contents are mixed thoroughly. Flush existing line with D<sub>5</sub>W, or use a separate line. Don't use an in-line filter. If infusion exceeds 2 hours, shake infusion bag every 2 hours.
- Prepare amphotericin B liposomal complex by adding 12 ml sterile water for injection (without bacteriostatic agent) to each 50-mg vial to achieve a concentration of 4 mg amphotericin B per milliliter. Immediately shake vial vigorously for at least 30 seconds until all particles completely disperse. Withdraw prescribed dose of amphotericin B liposomal complex suspension. Then use a 5-micron filter to inject it into D<sub>5</sub>W to provide a final concentration of 1 to 2 mg/ml. Expect to use a lower concentration (0.2 to 0.5 mg/ml) for infants and young children. Flush existing line with D<sub>5</sub>W, or use a separate line. An in-line filter with a mean pore diameter of at least 1 micron may be used.

- Expect to give an antihistamine, antipyretic, or corticosteroid just before infusing amphotericin B to help minimize fever and shaking chills.
- Shake well before giving amphotericin B oral suspension. Drop suspension on tongue with calibrated dropper. Then tell patient to swish suspension in mouth for as long as possible before swallowing. If drug must be swabbed on, use a nonabsorbent swab.
- Give amphotericin B oral suspension between meals to permit prolonged contact with oral lesions.
- Assess I.V. insertion site regularly to detect extravasation of amphotericin B, which may cause severe local irritation. To minimize local thrombophlebitis, plan to add heparin to infusion or expect to administer amphotericin on alternate days, which also may help prevent anorexia. Alternate-day dose shouldn't exceed 1.5 mg/kg.
- Monitor renal function because of the risk of renal impairment. Plan to obtain serum creatinine level every other day while amphotericin B dosage is increasing and then at least twice weekly during therapy. If serum creatinine or BUN level increases significantly, expect to stop amphotericin B until renal function improves. Know that a cumulative dose of more than 4 g may cause irreversible renal dysfunction.
- Expect to monitor CBC and platelet count weekly during therapy to detect adverse hematologic effects. Also monitor serum calcium, magnesium, and potassium levels twice weekly to detect abnormalities.
- Use reconstituted amphotericin B within 24 hours if stored at room temperature, 1 week if refrigerated. Use reconstituted amphotericin B cholesteryl sulfate complex within 24 hours. Use amphotericin B lipid complex within 6 hours if stored at room temperature, 48 hours if refrigerated. Use diluted amphotericin B liposomal complex within 24 hours if refrigerated, but begin infusion within 6 hours.
- Be aware that false elevations of serum phosphate may occur when samples are analyzed using the PHOSm assay.

## **PATIENT TEACHING**

- Instruct patient to shake bottle of oral suspension well before each dose; to drop suspension directly on his tongue using calibrated dropper; and then to swish suspension in his mouth for as long as possible before swallowing. If prescriber orders drug to be swabbed onto oral lesions, tell patient to use nonabsorbent swab. Instruct him to take drug four times a day (between meals and at bedtime).

- Tell patient to notify prescriber if he develops local irritation, if existing symptoms worsen or return, or if new symptoms arise.

**ampicillin**

**ampicillin sodium**

**ampicillin trihydrate**

## **Class and Category**

*Pharmacologic class:* Aminopenicillin

*Therapeutic class:* Antibiotic

## **Indications and Dosages**

- *To treat GI infections and genitourinary infections (other than gonorrhea) caused by susceptible strains of Shigella, Salmonella typhi and other species, Escherichia coli, Proteus mirabilis, and enterococci*

### **CAPSULES, ORAL SUSPENSION**

**Adults and children weighing 20 kg (44 lb) or more.**  
500 mg every 6 hr.

**Children weighing less than 20 kg (44 lb).** 100 mg/kg daily in divided doses every 6 hr.

### **I.M. INJECTION, I.V. INFUSION, I.V. INJECTION**

**Adults and children weighing 40 kg (88 lb) or more.**

500 mg every 6 hr. For I.V. infusion, infuse over 15 to 30 min. For I.V. injection, inject slowly over 10 to 15 min and do not exceed 100 mg/ml.

**Children weighing less than 40 kg.**

50 mg/kg daily in divided doses every 6 to 8 hr. For I.V. infusion, infuse over 15 to 30 min. For I.V. injection, inject slowly over 10 to 15 min and do not exceed 100 mg/ml.

- *To treat uncomplicated gonorrhea caused by susceptible strains of non-penicillinase-producing Neisseria gonorrhoeae*

**CAPSULES, ORAL SUSPENSION**

**Adults and children.** 3.5 g as a single dose with 1 g of probenecid.

- *To treat respiratory tract infections caused by susceptible strains of non-penicillinase-producing Haemophilus influenzae, staphylococci, and streptococci, including Streptococcus pneumoniae*

**CAPSULES, ORAL SUSPENSION**

**Adults and children weighing 20 kg (44 lb) or more.**

250 mg every 6 hr.

**Children weighing less than 20 kg (44 lb).** 50 mg/kg daily in divided doses every 6 hr.

**I.M. INJECTION, I.V. INFUSION, I.V. INJECTION**

**Adults and children weighing 40 kg (88 lb) or more.**

250 to 500 mg every 6 to 8 hr. For I.V. infusion, infuse over 15 to 30 min. For I.V. injection, inject slowly over 10 to 15 min and do not exceed 100 mg/ml.

**Children weighing less than 40 kg.** 25 to 50 mg/kg daily in divided doses every 6 to 8 hr. For I.V. infusion, infuse

over 15 to 30 min. For I.V. injection, inject slowly over 10 to 15 min and do not exceed 100 mg/ml.

- *To treat septicemia; to treat bacterial meningitis caused by susceptible strains of *Neisseria meningitidis**

## **I.M. INJECTION, I.V. INFUSION, I.V. INJECTION**

**Adults and children.** 150 to 200 mg/kg daily I.V. in divided doses every 3 to 4 hr for at least 3 days; then continued I.M. For I.V. infusion, infuse over 15 to 30 min. For I.V. injection, inject slowly over 10 to 15 min and do not exceed 100 mg/ml.

- *To treat urethritis in males due to *N. gonorrhoeae**

## **I.M. INJECTION, I.V. INFUSION, I.V. INJECTION**

**Adult men.** Two doses of 500 mg at 8- or 12-hr intervals. May repeat or extend treatment, if needed. For I.V. infusion, infuse over 15 to 30 min. For I.V. injection, inject slowly over 10 to 15 min and do not exceed 100 mg/ml.

- *To treat soft tissue infections caused by susceptible strains of staphylococci and streptococci organisms*

## **I.M. INJECTION, I.V. INFUSION, I.V. INJECTION**

**Adults and children weighing 40 kg (88 lb) or more.** 250 to 500 mg every 6 or 8 hr. For I.V. infusion, infuse over 15 to 30 min. For I.V. injection, inject slowly over 10 to 15 min and do not exceed 100 mg/ml.

**Adults and children weighing less than 40 kg (88 lb).** 25 to 50 mg/kg daily in divided doses every 6 to 8 hr. For I.V. infusion, infuse over 15 to 30 min. For I.V. injection, inject slowly over 10 to 15 min and do not exceed 100 mg/ml.

---

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	Unknown

Route	Onset	Peak	Duration
I.V.	Immediate	Unknown	Unknown

## Mechanism of Action

Inhibits bacterial cell wall synthesis. The rigid, cross-linked cell wall is assembled in several steps. Ampicillin exerts its effects on susceptible bacteria in the final stage of the cross-linking process by binding with and inactivating penicillin-binding proteins (enzymes responsible for linking the cell wall strands). This action causes bacterial cell lysis and death.

## Incompatibilities

Don't mix ampicillin and any amino-glycoside in the same I.V. bag, bottle, or tubing; otherwise, both drugs will be inactivated. If patient must receive both drugs, administer them in separate sites at least 1 hour apart.

## Contraindications

Hypersensitivity to ampicillin, other penicillins, or their components; infection caused by penicillinase-producing organism

## Interactions

### DRUGS

*allopurinol*: Increased risk of rash, particularly in hyperuricemic patient

*aminoglycosides*: Possibly inactivated action *bacteriostatic antibiotics such as chloramphenicol, erythromycins,*

*sulfonamides, tetracyclines*: Possibly impaired action of ampicillin

*live-virus vaccines such as BCG (intravesical) and typhoid*: May decrease effectiveness of vaccine

*oral anticoagulants*: Increased risk of bleeding

*oral contraceptives*: Possibly reduced contraceptive effectiveness and breakthrough bleeding

## Adverse Reactions

**CNS**: Chills, fatigue, fever, headache, malaise

**CV**: Chest pain, edema, thrombophlebitis

**EENT**: Epistaxis, glossitis, **laryngeal stridor**, mucocutaneous candidiasis, stomatitis, **throat tightness**

**GI**: Abdominal distention, ***Clostridium difficile***-associated diarrhea, enterocolitis, flatulence, gastritis, nausea, **pseudomembranous colitis**, vomiting

**GU**: Dysuria, urine retention, vaginal candidiasis

**HEME**: **Agranulocytosis**, anemia, eosinophilia, **leukopenia**, **thrombocytopenia**, **thrombocytopenic purpura**

**SKIN**: **Erythema multiforme**; erythematous, mildly pruritic maculopapular rash or other types of rash; **exfoliative dermatitis**; pruritus; urticaria

**Other**: **Anaphylaxis**, **angioedema**, injection-site pain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LABOR & DELIVERY

- Oral drug is poorly absorbed during labor.
- It is not known if drug has any immediate or delayed adverse effects on the fetus, prolongs the duration of labor, or increases the likelihood that forceps delivery or other obstetrical intervention or resuscitation of the newborn will be needed.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Avoid giving ampicillin to patients with mononucleosis because of increased risk of rash.
- Expect to give ampicillin for 48 to 72 hours after patient becomes asymptomatic. For streptococcal infection, expect to give ampicillin for at least 10 days after cultures show streptococcal eradication to reduce risk of rheumatic fever or glomerulonephritis.
- Dilute ampicillin for I.M. use by adding (depending on manufacturer) 1.2 ml of sterile water or bacteriostatic water for injection to each 125-mg vial, 1 ml of diluent to each 250-mg vial, 1.8 ml of diluent to each 500-mg vial, 3.5 ml of diluent to each 1-g vial, or 6.8 ml of diluent to each 2-g vial.
- Dilute ampicillin for intermittent infusion by adding 5 ml of sterile water or bacteriostatic water for injection to each 125-, 250-, or 500-mg vial or 7.4 to 10 ml of diluent to each 1- or 2-g vial. Infuse in suitable diluent at less than 30 mg/ml.

**WARNING** For I.V. infusion, infuse over 15 to 30 min. For I.V. injection, inject slowly over 10 to 15 min and do not exceed 100 mg/ml. More rapid infusion may cause seizures.

- Monitor patient closely for anaphylaxis, which may be life-threatening. Patients at greatest risk are those with a history of multiple allergies, hypersensitivity to cephalosporins, or a history of asthma, hay fever, or urticaria.

**WARNING** Stop drug in an anaphylactic reaction, notify prescriber immediately, and provide immediate treatment with epinephrine, airway management, oxygen, and I.V. corticosteroids, as needed.

- Notify prescriber if patient has evidence of superinfection; expect to stop drug and provide appropriate treatment.
- Closely monitor results of renal and liver function tests and CBCs if long-term or high-dose ampicillin therapy is required.
- Monitor patient closely for diarrhea, which may be pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold ampicillin and administer fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

## PATIENT TEACHING

- Emphasize the importance of taking the full course of ampicillin exactly as prescribed.
- Tell patient to take oral dose with 8 ounces of water 30 minutes before or 2 hours after meals.
- Instruct patient to shake suspension well before each use, keep bottle tightly closed between uses, and discard unused portion after 14 days if refrigerated or 7 days if stored at room temperature.
- Review signs of allergic reaction; if they occur, tell patient to hold next ampicillin dose and contact prescriber immediately.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools may occur 2 or more months after antibiotic therapy and may be serious, requiring prompt treatment.

# angiotensin II

## Giapreza

### Class and Category

*Pharmacologic class:* Peptide hormone of the renin-angiotensin-aldosterone system

*Therapeutic class:* Antihypertensive

### Indications and Dosages

- *To increase blood pressure in patients with septic or other distributive shock*

### I.V. INFUSION

**Adults.** *Initial:* 20 ng/kg/min continuously then increased in increments of up to 15 ng/kg/min every 5 minutes, as needed, to achieve or maintain target blood pressure but not to exceed 80 ng/kg/min during first 3 hr and not to exceed 40 ng/kg/min for remainder of treatment. When no longer needed, dosage decreased in increments of up to 15 ng/kg/min every 5 to 15 minutes, with adjustments made based upon blood pressure.

***DOSAGE ADJUSTMENT*** Dosage may be decreased to as low as 1.25 ng/kg/min in patients sensitive to angiotension II effects.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	Unknown
I.V.	Within 1 min	Unknown	Unknown

## Mechanism of Action

Binds to the G-protein-coupled angiotensin II receptor type I on vascular smooth muscle cells, which stimulates myosin and causes smooth muscle contraction. These actions raise blood pressure by increasing aldosterone release and causing vasoconstriction.

## Contraindications

Hypersensitivity to angiotensin II components

## Interactions

### DRUGS

*angiotensin-converting enzyme (ACE) inhibitors*: Possibly increased response to angiotensin II

*angiotensin II receptor blockers (ARBs)*: Possibly decreased response to angiotensin II

## Adverse Reactions

**CNS:** Delirium

**CV:** Arterial and venous thrombotic events, deep vein thrombosis, peripheral ischemia, tachycardia

**ENDO:** Hyperglycemia

**HEME:** Thrombocytopenia

**Other:** Acidosis, fungal infection

## Childbearing Considerations

## **PREGNANCY**

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding, once condition has stabilized.

## **Nursing Considerations**

- Administer angiotensin II only as an intravenous infusion, adjusting dosage every 5 minutes as needed. Do not exceed a dosage of 80 ng/kg/min during first 3 hours of treatment or 40 ng/kg/min for remainder of treatment.
- Dilute angiotensin II in 0.9% sodium chloride solution prior to use to achieve a final concentration of 5,000 ng/ml or 10,000 ng/ml. To prepare a 5,000 ng/ml solution, use angiotensin II vial strength of 2.5 mg/ml, withdraw 1 ml from vial, and add to 500-ml infusion bag of 0.9% sodium chloride. To prepare a 10,000 ng/ml solution, use angiotensin II vial strength of 2.5 mg/ml, withdraw 1 ml from vial, and add to a 250-ml infusion bag of 0.9% sodium chloride or use angiotensin II vial strength 5 mg/2 ml, withdraw 2 ml of angiotensin II, and add to 500-ml infusion bag of 0.9% sodium chloride.
- Know that diluted solution may be stored at room temperature or in refrigerator. Discard unused prepared solution after 24 hours regardless of how it was stored.
- Monitor patient closely for thrombotic events. Take precautions to prevent these events, especially deep venous thromboses.

## **PATIENT TEACHING**

- Instruct patient on angiotensin II use, if patient is able to understand.

- Tell patient to report any abnormal symptoms, if patient is able to understand.

# anidulafungin

**Eraxis**

## Class and Category

*Pharmacologic class:* Echinocandin

*Therapeutic class:* Antifungal

## Indications and Dosages

- *To treat Candidemia and other forms of Candida infections (intra-abdominal abscess and peritonitis)*

### I.V. INFUSION

**Adults.** 200 mg on day 1 infused over 3 hr, followed by 100 mg daily infused over 90 min (not to exceed 1.4 mg/min or 84 ml/hr when reconstituted and diluted) and continued for a minimum of 14 days and for at least 14 days following last positive culture.

- *To treat esophageal candidiasis*

### I.V. INFUSION

**Adults.** 100 mg on day 1 infused over 90 min, followed by 50 mg daily infused over 45 min (not to exceed 1.4 ml/min or 84 ml/hr when reconstituted and diluted) for a minimum

of 14 days and continued for at least 7 days following resolution of symptoms.

## Mechanism of Action

Inhibits glucan synthase, an enzyme present in fungal cells. This results in inhibition of the formation of an essential D-glucan component of the fungal cell wall, thereby eliminating the fungal infection.

## Incompatibilities

Do not use with other intravenous substances, additives, or medications other than 5% Dextrose Injection and normal saline because compatibility is unknown.

## Contraindications

Hypersensitivity to anidulafungin, its components, or other echinocandins

## Interactions

None reported

## Adverse Reactions

**CNS:** Confusion, depression, dizziness, fever, headache, insomnia, rigors, **seizures**

**CV:** **Atrial fibrillation**, chest pain, **deep vein thrombosis**, hypertension **hypotension**, peripheral edema, **QT prolongation**, right bundle branch block, sinus arrhythmia, superficial thrombophlebitis, **ventricular extrasystoles**

**EENT:** Blurred vision, eye pain, oral candidiasis, visual disturbance

**ENDO:** Hot flashes, hyperglycemia, **hypoglycemia**

**GI:** Abdominal pain, cholestasis, constipation, diarrhea, dyspepsia, elevated liver enzymes, **hepatic necrosis**, nausea, vomiting

**GU:** Elevated blood creatinine levels, UTI

**HEME:** Anemia, **leukocytosis**, **prolonged prothrombin time**, **thrombocytopenia**

**MS:** Back pain

**RESP:** **Bronchospasm**, cough, dyspnea, pleural effusion, pneumonia, **respiratory distress**

**SKIN:** Diaphoresis, erythema, flushing, pruritus, rash, ulceration, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **bacteremia**, **clostridial infection**, dehydration, **hyperkalemia**, **hypokalemia**, **hypomagnesemia**, infusion-related reactions, **multiorgan failure**, **sepsis**, systemic *Candida* infection in the arm used for infusion

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm although animal studies suggest it may.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Reconstitute each 50-mg vial with 15 ml of sterile water for injection and each 100-mg vial with 30 ml of sterile water for injection to provide a concentration of 3.33 mg/ml. The reconstituted solution can be stored for up to 24 hours at temperatures up to 25°C (77°F) prior to dilution into the infusion solution.
- Transfer the contents of the reconstituted vial(s) aseptically into the appropriately sized I.V. bag or bottle containing either 5% Dextrose Injection or normal saline following the manufacturer guidelines for the amount of infusion volume to use.
- Infuse at 1.4 ml/min (which is equivalent to 1.1 mg/min). Do not infuse at a higher rate because infusion-related adverse reactions that are possibly histamine-mediated may occur. If total infusion volume is 65 ml, infuse at least over 45 minutes; if total infusion volume is 130 ml, infuse over at least 90 minutes; and, if total infusion volume is 260 ml, infuse over at least 180 minutes. The infusion solution may be stored up to 48 hours at temperatures up to 25°C (77°F).
- Monitor patient's liver function and enzyme levels closely during anidulafungin therapy because significant hepatic dysfunction, hepatitis, or hepatic failure have been reported, although a causal relationship has not been established. If patient begins to complain of fatigue and shows signs of jaundice or his liver enzymes become abnormal, notify prescriber, as drug may be discontinued.

**WARNING** Monitor patient closely for hypersensitivity reactions that could lead to anaphylactic reactions, including shock. If present, withhold drug, notify prescriber, and be prepared to provide emergency treatment.

## PATIENT TEACHING

- Instruct patient to promptly report any hypersensitivity reaction such as flushing, hives, itching, rash, difficulty breathing, or dizziness.

- Advise patient to comply with blood tests that may be ordered to monitor reaction to anidulafungin.
- Tell women of childbearing age that anidulafungin may cause fetal harm. If pregnancy is suspected or confirmed, or patient is planning to breastfeed, advise patient to alert prescriber.

## antihemophilic factor (recombinant) PEGylated- aucl

**Jivi**

### Class and Category

*Pharmacologic class:* Coagulation Factor VIII

*Therapeutic class:* Coagulant

### Indications and Dosages

- *To treat on-demand and control of bleeding episodes in previously treated patients with hemophilia A*

#### I.V. INFUSION

**Adults and adolescents.** *For minor bleeding:* 10 to 20 international units and repeated every 24 to 48 hr until bleeding resolved. *For moderate bleeding:* 15 to 30 international units and repeated every 24 to 48 hr until bleeding resolved. *For major bleeding:* 30 to 50 international units and repeated every 8 to 24 hr until

bleeding is resolved. Infused over 1 to 15 min, with rate of administration adapted to patient's response. *Maximum:* 2.5 ml/min infusion rate.

- *To manage perioperative bleeding in previously treated patients with hemophilia A*

## **I.V. INFUSION**

**Adults and adolescents.** *For minor surgery:* 15 to 30 international units and repeated every 24 hr for at least 1 day and until healing is achieved. *For major surgery:* 40 to 50 international units and repeated every 12 to 24 hr until adequate wound healing is complete, then therapy continued for at least another 7 days to maintain Factor VIII activity of 30% to 60%. Infused over 1 to 15 min, with rate of administration adapted to patient's response. *Maximum:* 2.5 ml/min infusion rate.

- *To reduce frequency of bleeding episodes in previously treated patients with hemophilia A*

## **I.V. INFUSION**

**Adults and adolescents.** *Initial:* 30 to 40 international units twice weekly with regimen adjusted to 45 to 60 international units every 5 days based on bleeding episodes. Dosing then adjusted to less or more frequent dosing as needed. Infused over 1 to 15 min, with rate of administration adapted to patient's response. *Maximum:* 2.5 ml/min infusion rate.

## **Mechanism of Action**

Temporarily replaces the missing coagulation Factor VIII.

## **Contraindications**

Hypersensitivity to antihemophilic factor (recombinant) PEGylated-aucI or to hamster or mouse proteins, polyethylene glycol, or their components

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Dizziness, fever, headache, insomnia

**CV:** Chest tightness, hypotension (mild)

**EENT:** Distorted sense of taste, **throat tightness**

**GI:** Abdominal pain, nausea, vomiting

**RESP:** Cough

**SKIN:** Erythema, **erythema multiforme**, flushing, pruritus, rash

**Other:** **Anaphylaxis**, anti-PEG antibody formation, injection-site reactions (pruritus, rash), neutralizing antibodies

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that dosage and duration of treatment depends on the severity of the Factor VIII deficiency, the location and extent of bleeding, and the patient's clinical condition.
- Be aware that potency assignment for the drug is determined using a chromogenic substrate assay.
- Monitor the Factor VIII activity of the drug in plasma, as ordered, knowing that the activity will be assessed using either a validated chromogenic substrate assay or a validated one-stage clotting assay.
- Know that calculation of the required dose of Factor VIII is based on one international unit of Factor VIII/kilogram ability to increase the plasma Factor VIII level by 2 international units/dl.
- Expect to adjust dose and frequency according to patient's clinical response, as ordered.
- Prepare antihemophilic factor (recombinant) PEGylated-aucI by first warming both the unopened vial and prefilled diluent syringe in your hands to a comfortable temperature (not to exceed 37°C [99°F]). Then remove the protective cap from the vial and cleanse the rubber stopper with a sterile alcohol swab, being careful not to handle the rubber stopper. Place the vial on a firm, nonskid surface. Peel off the paper cover on the vial adapter plastic housing. Do not remove the adapter from the plastic housing. Holding the adapter housing, place it over the product vial and firmly press down. The adapter will snap over the vial cap. Do not remove the adapter housing at this step. Holding the syringe by the barrel, snap the syringe cap off the tip. Do not touch the syringe tip with your hand or any surface. Set the syringe aside. Now remove and discard the adapter plastic housing. Attach the prefilled syringe to the vial adapter thread by turning clockwise. Remove the clear plastic plunger rod from the carton. Grasp the plunger rod by the top plate. Avoid touching the sides and threads of the plunger rod. Attach the plunger rod by turning it clockwise into the threaded rubber stopper of the prefilled syringe. Inject the diluent slowly by pushing down on the plunger rod. Swirl vial gently until all powder on all sides of the vial is dissolved. Do not shake vial. Be sure that all powder is completely dissolved. Do not use if solution contains visible particles or is cloudy. Push down on the plunger to push all air back into the vial. Then, while holding the plunger

down, turn the vial with syringe upside-down (inverted) so the vial is now above the syringe.

- Know that if the dose requires more than one vial, each vial must be reconstituted as described in the preceding bullet with the diluent syringe provided. Use a larger plastic syringe (not supplied) to combine the contents of the vials into one syringe. Filter the reconstituted product to remove potential particulate matter in the solution. Filtering is achieved by using the vial adapter. Withdraw all the solution through the vial adapter into the syringe by pulling the plunger rod back slowly and smoothly. Tilt the vial to the side and back to make sure all the solution has been drawn toward the large opening in the rubber stopper and into the syringe. Remove as much air as possible before removing the syringe from the vial by slowly and carefully pushing the air back into the vial. Detach the syringe with the plunger rod from the vial adapter by turning counter-clockwise. Attach the syringe to the infusion set provided and inject the reconstituted product intravenously.
- Administer the reconstituted drug as soon as possible after preparation. If unable to do so, store at room temperature for no longer than 3 hours. Infuse intravenously over 1 to 15 minutes, adapting the rate of administration to patient's response. Do not exceed the maximum infusion rate of 2.5 ml/min.
- Monitor patient for hypersensitivity reactions that could progress to anaphylaxis. If any signs or symptoms of an allergic reaction occur, immediately discontinue administration of the drug, notify prescriber, and initiate treatment according to institutional protocol.
- Be aware that neutralizing antibodies may form following the administration of antihemophilic factor (recombinant) PEGylated-aucI. If plasma Factor VIII activity levels are not attained or if bleeding is not controlled as expected with the administered dose, suspect the presence of a neutralizing antibody and notify prescriber. Expect testing for Factor VIII inhibitors and Factor VIII recovery. A low postinfusion Factor VIII level in the absence of detectable Factor VIII inhibitors indicates that the loss of drug effect is likely due to anti-PEG antibodies. In this situation, expect drug to be discontinued and know that patient will need to be switched to a previously effective Factor VIII product.

## **PATIENT TEACHING**

- Instruct patient to report early signs of an allergic reaction such as dizziness, nausea, and tightness of his chest or throat during or after the infusion. If patient is home, stress importance of seeking immediate emergency attention, as the reaction can progress to a life-threatening situation.

- Tell patient to notify prescriber or treatment center if he experiences a lack of response to the drug.
- Advise patient to consult his prescriber prior to traveling.

# apixaban

## Eliquis

### Class and Category

*Pharmacologic class:* Factor Xa inhibitor

*Therapeutic class:* Anticoagulant

### Indications and Dosages

- *To reduce the risk of stroke and systemic embolism in patients with nonvalvular atrial fibrillation*

#### TABLETS

**Adults.** 5 mg twice daily.

***DOSAGE ADJUSTMENT*** For patients with at least two of the following characteristics: 80 years or older, body weight of 60 kg (132 lbs) or less, or a serum creatinine of 1.5 mg/dl or greater; dosage decreased to 2.5 mg twice daily.

- *To prevent deep vein thrombosis following hip or knee replacement surgery*

#### TABLETS

**Adults.** 2.5 mg twice daily beginning 12 to 24 hours after surgery and lasting 12 days for knee replacement and 35

days for hip replacement.

- *To treat deep vein thrombosis and pulmonary embolism*

## **TABLETS**

**Adults.** 10 mg twice daily for 7 days followed by 5 mg twice daily.

- *To reduce risk of recurrence of deep vein thrombosis and pulmonary embolism*

## **TABLETS**

**Adults.** 2.5 mg twice daily following 6 months of treatment for deep vein thrombosis or pulmonary embolism.

***DOSAGE ADJUSTMENT*** For patients receiving 5 mg or 10 mg dosage twice daily, dosage reduced by 50% if patient also receiving combined strong dual inhibitors of cytochrome P450 3A4 (CYP3A4) and P-glycoprotein (P-gp) such as itraconazole, ketoconazole, or ritonavir. For patients receiving 2.5 mg dosage twice daily, coadministration with combined strong CYP3A4 and P-gp inhibitors are avoided.

## **Mechanism of Action**

Inhibits free and clot-bound factor Xa and prothrombinase activity. Although apixaban has no direct effect on platelet aggregation, it does indirectly inhibit platelet aggregation induced by thrombin. By inhibiting factor Xa, apixaban decreases thrombin generation and thrombus development.

## **Contraindications**

Active pathological bleeding, severe hypersensitivity to apixaban or its components

# Interactions

## DRUGS

*antiplatelets, aspirin, fibrinolytics, heparin NSAIDs (chronic use): Increased risk of bleeding*

*strong dual inducers of CYP3A4 and P-gp such as carbamazepine, phenytoin, rifampin, St. John's wort:*

Decreased effectiveness of apixaban

*strong dual inhibitors of CYP3A4 and P-gp such as itraconazole, ketoconazole, ritonavir: Increased effects of apixaban*

## Adverse Reactions

**CNS:** Hemorrhagic stroke, syncope

**CV:** Hypotension

**EENT:** Epitaxis, gingival bleeding, ocular hemorrhage

**GI:** Elevated bilirubin and liver enzymes, GI bleeding or hemorrhage, fresh bleeding from rectum, hematemesis, melena, rectal hemorrhage

**GU:** Hematuria, vaginal hemorrhage

**HEME:** Excessive bleeding, including hemorrhage, hemorrhagic anemia, thrombocytopenia

**SKIN:** Ecchymosis, petechiae, rash

**MS:** Muscle hemorrhage

**RESP:** Hemoptysis

**Other:** Anaphylaxis, angioedema, elevated alkaline phosphatase, hematomas at injection sites

## Childbearing Considerations

## **PREGNANCY**

- It is not known if drug can cause fetal harm but there is the potential for hemorrhage.
- Drug use is not recommended during pregnancy unless no other alternative is available.

## **LABOR & DELIVERY**

- Use with caution only if absolutely necessary and no other alternative is available because there is a potential for hemorrhage. A shorter acting anticoagulant should be considered as delivery approaches.

## **LACTATION**

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential adverse reactions in the breastfed infant.

## **Nursing Considerations**

- Know that apixaban should not be given to patients with severe hepatic dysfunction. Drug should also not be given to patient with triple positive antiphospholipid syndrome because drug therapy has been associated with increased rates of recurrent thrombotic events.
- Crush tablet and mix with apple juice or water or put in applesauce and administer immediately for patient unable to swallow whole tablets. For patient with a nasogastric tube, crush tablet and suspend in 60 ml of 5% dextrose and water or plain water and immediately administer through the nasogastric tube.
- Expect apixaban to be discontinued 48 hours before an invasive procedure or surgery if patient has a moderate or high risk of hemorrhage and 24 hours before an invasive procedure or surgery if patient has a mild risk of hemorrhage.
- Be aware that manufacturer guidelines should be followed when patient is switching from or to other anticoagulants. For example, when patient is switching from warfarin to apixaban therapy, expect warfarin to be

discontinued and apixaban started when the International Normalized Ratio (INR) is below 2. When switching from apixaban to warfarin, expect apixaban to be discontinued and both a parenteral anticoagulant and warfarin given at the time the next dose of apixaban would have been given. Then the parenteral anticoagulant is discontinued when INR reaches an acceptable range. When switching between apixaban and anticoagulants other than warfarin, expect to discontinue the one being taken and begin the other at the next scheduled dose.

- Be aware that if apixaban is discontinued prematurely and adequate alternative anticoagulation is not present, the risk of thrombosis increases.

**WARNING** Monitor patient closely for bleeding, as apixaban may cause life-threatening bleeding. Expect drug to be discontinued with active pathological hemorrhage and expect to give the antidote, coagulation factor Xa (recombinant), inactivated-zhzo (Andexxa) to reverse effects of anticoagulation. Know that effects of apixaban may persist for at least 24 hours after the last dose, but that activated oral charcoal can reduce the absorption of apixaban, thereby lowering apixaban plasma concentration if given close to last dose of apixaban.

## **PATIENT TEACHING**

- Emphasize the importance of taking apixaban exactly as prescribed.
- Tell patient unable to swallow whole tablets to crush tablet and mix with apple juice or water or mix with applesauce and take immediately.
- Tell patient not to stop taking apixaban without first consulting prescriber. If patient misses a dose, instruct him to take it as soon as possible on the same day and resume the dosing schedule the next day. Caution patient not to double dose to make up for the missed dose the day before.
- Advise patient to report any unusual bleeding or bruising to the prescriber. Inform patient that it may take longer for her to stop bleeding and to take bleeding precautions, such as avoiding the use of a razor and using a soft-bristle toothbrush.

- Tell patient to alert all prescribers to use of apixaban therapy before any invasive procedure, including dental work, is scheduled.
- Advise female patient to notify prescriber immediately if pregnancy is suspected or known.

## apremilast

### Otezla

## Class and Category

*Pharmacologic class:* Phosphodiesterase 4 inhibitor

*Therapeutic class:* Antirheumatic

## Indications and Dosages

- *To treat active psoriatic arthritis; to treat moderate to severe plaque psoriasis in patients who are candidates for phototherapy or systemic therapy; to treat oral ulcers associated with Behçet's Disease.*

### **TABLETS**

**Adults.** *Initial:* 10 mg in a.m. on day 1; 10 mg in a.m. and p.m. on day 2; 10 mg in a.m. and 20 mg in p.m. on day 3; 20 mg in a.m. and p.m. on day 4; 20 mg in a.m. and 30 mg in p.m. on day 5; and 30 mg in a.m. and p.m. on day 6 and thereafter. *Maintenance:* 30 mg in a.m. and p.m.

***DOSAGE ADJUSTMENT*** For patients with severe renal impairment (creatinine clearance less than 30 ml/min), dosage titration decreased to once daily using only the a.m.

titration schedule and maintenance dosage kept at 30 mg once daily in a.m.

## Mechanism of Action

Inhibits phosphodiesterase 4, which is specific for cyclic adenosine monophosphate (cAMP). This action results in increased intracellular cAMP levels, which are thought to help relieve symptoms of psoriatic arthritis.

## Contraindications

Hypersensitivity to apremilast or its components

## Interactions

### DRUGS

*strong CYP450 inducers such as rifampin:* Decreased apremilast exposure with loss of effectiveness

## Adverse Reactions

**CNS:** Depression, fatigue, headache, insomnia, migraine, **suicidal ideation**

**EENT:** Nasopharyngitis

**GI:** Anorexia, diarrhea, dyspepsia, gastroesophageal reflux disease, nausea, upper abdominal pain, vomiting

**MS:** Arthralgia, back pain

**RESP:** Bronchitis, cough, upper respiratory infection

**SKIN:** Rash

**Other:** Weight loss

## Childbearing Considerations

## **PREGNANCY**

- Pregnancy exposure registry: 1-877-311-8972 or <https://mothertobaby.org/ongoing-study/otezla/>.
- It is not known if drug can cause fetal harm although some studies suggest an increased risk for fetal loss.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Watch patient closely for evidence of depression, especially when apremilast therapy begins, because apremilast therapy may increase risk of depression and possibly lead to suicidal thinking or behavior.
- Monitor patient's weight regularly because apremilast may cause weight loss. Notify prescriber if weight loss occurs that is unexplained or is significant.

## **PATIENT TEACHING**

- Tell patient to follow titration schedule exactly, as this will help reduce the incidence and severity of gastrointestinal symptoms associated with initial therapy.
- Instruct patient to swallow the tablets whole and not to crush, split, or chew the tablets.
- Instruct caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts, and to report concerns to prescriber immediately.

# aprepitant

**Cinvanti, Emend**

# fosaprepitant dimeglumine

**Emend for Injection**

## Class and Category

*Pharmacologic class:* Substance P/neurokinin 1 (NK1) receptor antagonist

*Therapeutic class:* Antiemetic

## Indications and Dosages

- *As adjunct to prevent acute and delayed nausea and vomiting associated with moderately to highly emetogenic chemotherapy, including high-dose cisplatin*

### CAPSULES (EMEND)

**Adults and children age 12 and over.** 125 mg 1 hr before chemotherapy treatment, followed by 80 mg daily 1 hr before chemotherapy on day 2 and 3, or if no chemotherapy, 80 mg in morning on day 2 and 3.

### I.V. INFUSION (EMEND FOR INJECTION)

**Adults receiving a single dose regimen.** 150 mg as a single dose infused over 20 to 30 min before chemotherapy.

## **I.V. INFUSION (CINVANTI)**

**Adults receiving a single dose regimen.** 130 mg as a single dose infused over 30 min and completed about 30 min prior to chemotherapy on day 1 only.

## **I.V. INJECTION (CINVANTI)**

**Adults receiving a single dose regimen.** 130 mg as a single dose administered over two minutes and given 30 minutes prior to chemotherapy.

## **I.V. INFUSION (CINVANTI) FOLLOWED BY CAPSULES (EMEND)**

**Adults receiving moderately emetogenic cancer chemotherapy as a 3-day regimen.** 100 mg as a single dose infused over 30 min about 30 min prior to chemotherapy on day 1, followed by 80 mg of oral aprepitant on days 2 and 3.

## **I.V. INJECTION (CINVANTI) FOLLOWED BY CAPSULES (EMEND)**

**Adults receiving moderately emetogenic cancer chemotherapy as a 3-day regimen.** 100 mg as a single dose administered over 2 minutes and given 30 minutes before chemotherapy on day 1, followed by 80 mg of oral aprepitant on days 2 and 3.

## **ORAL SUSPENSION (EMEND)**

**Adults and children age 12 and over who cannot swallow oral capsules:** 125 mg 1 hr before chemotherapy treatment, followed by 80 mg daily 1 hr before chemotherapy on day 2 and 3, or if no chemotherapy, 80 mg in morning on day 2 and 3.

**Children 6 months to less than 12 years:** 3 mg/kg (maximum 125 mg) on day 1, followed by 2 mg/kg (maximum 80 mg) 1 hr before chemotherapy on day 2 and 3, or if no chemotherapy, 2 mg/kg (maximum 80 mg) in morning on day 2 and 3.

- *To prevent nausea and vomiting associated with moderately to highly emetogenic chemotherapy with single-day pediatric chemotherapy regimens*

## **I.V. INFUSION (EMEND FOR INJECTION)**

**Adolescents age 12 to 17.** 150 mg as a single dose infused over 30 min and completed about 30 min prior to chemotherapy on day 1 only.

**Children age 2 to less than 12.** 4 mg/kg (maximum 150 mg) as a single dose infused over 60 min and completed about 30 min prior to chemotherapy on day 1 only.

**Children 6 months to less than 2 years weighing at least 6 kg (13.2 lb).** 5 mg/kg (maximum 150 mg) as a single dose infused over 60 min and completed about 30 min prior to chemotherapy on day 1 only.

- *To prevent nausea and vomiting associated with moderately to highly emetogenic chemotherapy with multi-day pediatric chemotherapy regimens*

## **I.V. INFUSION (EMEND FOR INJECTION), CAPSULES (EMEND), ORAL SUSPENSION (EMEND)**

**Adolescents age 12 to 17.** 115 mg as a single dose infused over 30 min and completed about 30 min prior to chemotherapy on day 1 followed by 80 mg daily of oral aprepitant on days 2 and 3.

**Children age 6 months to less than 12 years weighing at least 6 kg (13.2 lb).** 3 mg/kg (maximum 115 mg) as a

single dose infused over 60 min and completed about 30 min prior to chemotherapy on day 1, followed by 80 mg daily of oral aprepitant in suspension form on days 2 and 3.

Route	Onset	Peak	Duration
P.O., I.V.	Unknown	4 hr	Unknown

## Mechanism of Action

Crosses the blood-brain barrier to occupy brain NK1 receptors, which prevents nerve transmission of signals that cause nausea and vomiting.

## Incompatibilities

Do not mix aprepitant with any solutions containing divalent cations (e.g., calcium, magnesium), including Lactated Ringer's solution and Hartmann's solution.

## Contraindications

Concurrent use of primozide, hypersensitivity to aprepitant or its components

## Interactions

### DRUGS

*carbamazepine, other CYP3A4 inducers, phenytoin, rifampin*: Possibly decreased blood aprepitant level  
*CYP3A4 inhibitors (such as clarithromycin, diltiazem, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, and troleandomycin)*: Increased blood aprepitant level

*CYP3A4 substrates (such as astemizole, benzodiazepines, cisapride, docetaxel, etoposide, imatinib, irinotecan, paclitaxel, pimozide, terfenadine, vinblastine, vincristine, and vinorelbine):* Increased level of CYP3A4 substrates, resulting in possibly serious or life-threatening adverse reactions

*dexamethasone, methylprednisolone:* Increased effects of these drugs and risk of adverse reactions

*ifosfamide:* Increased risk of neurotoxicity and possibly other serious or life-threatening adverse reactions

*oral contraceptives:* Possibly decreased effectiveness of hormonal contraceptives

*paroxetine:* Possibly decreased blood level of both drugs

*warfarin:* Decreased effectiveness of warfarin and decreased prothrombin time

## **Adverse Reactions**

**CNS:** Anxiety, asthenia, confusion, depression, dizziness, fatigue, fever, headache, hypoesthesia, hypothermia, insomnia, malaise, peripheral or sensory neuropathy, rigors, somnolence, syncope, tremor

**CV:** **Bradycardia**, **deep vein thrombosis**, edema, hypertension, **hypotension**, **MI**, palpitations, peripheral edema, tachycardia, thrombophlebitis at injection site

**EENT:** Conjunctivitis, dry mouth, increased salivation, mucous membrane alteration, nasal discharge, oral candidiasis, oropharyngeal pain, pharyngitis, stomatitis, taste perversion, tinnitus, vocal disturbance

**ENDO:** Hot flashes, hyperglycemia

**GI:** Abdominal pain, anorexia, constipation, diarrhea, dysphagia, elevated liver enzymes, epigastric discomfort, flatulence, gastritis, gastroesophageal reflux, heartburn,

hiccups, nausea, obstipation (intractable constipation), vomiting

**GU:** Dysuria, elevated BUN and serum creatinine levels, hematuria, leukocyturia, proteinuria, **renal insufficiency**, UTI

**HEME:** Anemia, **febrile neutropenia**, hematoma, leukocytosis, **leukopenia**, **neutropenia**, **thrombocytopenia**

**MS:** Arthralgia, back pain, muscle weakness, musculoskeletal pain, myalgia, pelvic pain

**RESP:** Cough, dyspnea, **hypoxia**, **non- small-cell lung carcinoma**, **pneumonitis**, **pulmonary embolism**, **respiratory depression or insufficiency**, respiratory tract infection

**SKIN:** Acne, alopecia, diaphoresis, flushing, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **anaphylactic shock**, **angioedema**, candidiasis, dehydration, elevated alkaline phosphatase, herpes simplex, **hypokalemia**, **hyponatremia**, infusion-site pain or induration, **malignant neoplasm**, **septic shock**, weight loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## REPRODUCTION

- Drug may reduce hormonal contraceptive effectiveness.
- Patient should be instructed to use an effective alternative or back-up nonhormonal contraceptive, such as spermicides or male partners' use of condoms, during therapy and for 1 month following last dose.

## Nursing Considerations

- Use caution when giving aprepitant to patients with severe hepatic insufficiency because drug's effects on such patients aren't known.
- Expect to administer aprepitant with dexamethasone and a 5-HT<sub>3</sub> antagonist, such as dolasetron, granisetron, or ondansetron for maximum antiemetic effects.
- Administer capsule form only to children age 12 and over. Suspension form should be administered to children under 12 or to an older patient who cannot swallow capsules.
- Know that when drug is administered intravenously, it is given as the first dose 30 minutes before chemotherapy.
- Reconstitute parenteral aprepitant (Cinvanti brand) for infusion by aseptically filling an infusion bag with 100 ml of 0.9% sodium chloride injection, USP, or 5% Dextrose for Injection, USP. Then withdraw 18 ml for 130-mg dose or 14 ml for 100-mg dose from drug vial and transfer it into the infusion bag. Gently invert the bag four or five times. Avoid shaking. Before administration, inspect bag for particulate matter and discoloration.
- Prepare parenteral aprepitant (Cinvanti brand) for injection by aseptically withdrawing 18 ml for the 130 mg dose or 14 ml for the 100 mg dose from the vial. Do not dilute. Inject over two minutes. Flush infusion line with normal saline before and after administration.
- Reconstitute parental aprepitant (Emend brand) by injecting 5 ml normal saline for injection along vial wall to prevent foaming. Swirl vial gently. Withdraw contents from vial and add to an infusion bag containing 110 ml normal saline solution. Gently invert the bag two or three times.

Administer over 15 minutes. Reconstituted solution may be stored at room temperature for 24 hours.

**WARNING** Monitor patient closely for hypersensitivity reactions, which could include anaphylaxis and anaphylactic shock during or soon after *administration* of drug. Symptoms to be alert for include dyspnea, erythema, flushing, hypotension, and syncope. If a hypersensitivity reaction occurs, stop infusion *or injection* if still being given, notify prescriber, expect drug to be discontinued, and be prepared to provide supportive care.

- Be aware that ifosfamide-induced neurotoxicity may occur after aprepitant and ifosfamide have been coadministered.

## **PATIENT TEACHING**

- Instruct patient to take 125-mg dose of oral aprepitant 1 hour before chemotherapy, 80-mg dose in the morning for 2 days after chemotherapy, or 40-mg dose within 3 hours before induction of anesthesia.
- Instruct patient to report an allergic reaction such as difficulty breathing or swallowing, dizziness, fainting, flushing, hives, itching, or rash and seek immediate medical attention.
- Tell female patients taking hormonal contraceptives to use an alternative or backup method of contraception during aprepitant therapy and for 1 month after last dose because drug reduces effectiveness of hormonal contraceptives.
- Tell patient taking chronic warfarin therapy to have clotting status monitored closely especially at 7 to 10 days during each chemotherapy cycle in which the drug is used.
- Caution patient to inform prescriber of any drugs he's taking, including OTC drugs and herbal preparations, because they may interact with aprepitant.

# argatroban

## Class and Category

*Pharmacologic class:* Direct thrombin inhibitor

*Therapeutic class:* Anticoagulant

## Indications and Dosages

- *To prevent or treat thrombosis in patients with heparin-induced thrombocytopenia (HIT)*

### I.V. INFUSION

**Adults without hepatic impairment.** 2 mcg/kg/min as a continuous infusion. *Maximum:* 10 mcg/kg/min.

***DOSAGE ADJUSTMENT*** Dosage adjusted as prescribed to maintain patient's APTT at 1.5 to 3 times the initial baseline value, not to exceed 100 sec. Initial dosage reduced to 0.5 mcg/kg/min for patients with moderate or severe hepatic impairment.

- *To prevent or treat thrombosis in patients with or at risk for HIT when undergoing percutaneous coronary intervention (PCI)*

### I.V. INFUSION

**Adults without hepatic impairment.** *Initial:* 350 mcg/kg over 3 to 5 min followed by continuous infusion of 25 mcg/kg/min.

***DOSAGE ADJUSTMENT*** Dosage adjusted as prescribed to keep activated clotting time (ACT) at 300 to 450 sec. If ACT is less than 300 sec, additional I.V. bolus dose of 150 mcg/kg

given and infusion increased to 30 mcg/kg/min; if ACT exceeds 450 sec, dosage reduced to 15 mcg/kg/min. For dissection, impending abrupt closure, thrombus formation during PCI, or inability to reach or keep ACT above 300 sec, additional bolus dose of 150 mcg/kg given and infusion increased to 40 mcg/kg/min.

Route	Onset	Peak	Duration
I.V.	Immediate	3-4 hr	Unknown

## Mechanism of Action

Forms a tight bond with thrombin, neutralizing this enzyme's actions, even when the enzyme is trapped within clots. Thrombin causes fibrinogen to convert to fibrin, which is essential for clot formation.

## Contraindications

Active major bleeding, hypersensitivity to argatroban or its components

## Interactions

### DRUGS

*heparin, oral anticoagulants:* Increased risk of bleeding

## Adverse Reactions

**CNS:** Cerebrovascular bleeding, fever, headache

**CV:** Atrial fibrillation, cardiac arrest, hypotension, unstable angina, ventricular tachycardia

**GI:** Abdominal pain, anorexia, diarrhea, elevated liver enzymes, **GI bleeding, melena**, nausea, vomiting

**GU:** Elevated BUN and serum creatinine levels, hematuria (microscopic), UTI

**HEME:** **Hemorrhage, hypoprothrombinemia, usual bleeding** or bruising

**RESP:** Cough, dyspnea, **hemoptysis**, pneumonia

**SKIN:** Bleeding at puncture site, rash

**Other:** **Sepsis**

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm due to increased risk of bleeding.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Use with caution during labor and delivery.
- Use of drug increases risk of bleeding for both the mother and fetus/neonate.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Know that argatroban isn't recommended for PCI patients with significant hepatic disease or AST/ALT levels three times or more the upper limits of normal.

- Reconstitute drug to 1 mg/ml before giving.
- Protect solution from direct sunlight.

**WARNING** Monitor patients with thrombocytopenia or those receiving daily doses of salicylates greater than 6 g for signs and symptoms of bleeding; these patients are at increased risk of bleeding from hypoprothrombinemia.

**WARNING** Expect to perform blood coagulation tests before and 2 hours after start of therapy because of the major risk of bleeding associated with argatroban. Be aware that coagulopathy must be ruled out before therapy starts. When giving drug to a patient undergoing PCI, expect to check ACT 5 to 10 minutes after each bolus and each infusion rate change and every 20 to 30 minutes during the PCI.

- Monitor the following patients for signs and symptoms of bleeding which may become severe and occur at any site in the body because they're at increased risk during argatroban therapy; patients who have recently had a large vessel puncture or organ biopsy, lumbar puncture, major bleeding (including intracranial, GI, intraocular, retroperitoneal, or pulmonary bleeding), major surgery (including brain, eye, or spinal cord surgery), spinal anesthesia, or stroke; patients with vascular or organ abnormalities, such as advanced renal disease, dissecting aortic aneurysm, diverticulitis, hemophilia, hepatic disease (especially if associated with a deficiency of vitamin K-dependent clotting factors), infective endocarditis inflammatory bowel disease, or peptic ulcer disease such as severe uncontrolled hypertension; and women with active menstruation. Risk of bleeding, especially hemorrhage, is also increased with concomitant use with other anticoagulants, antiplatelets, and thrombolytics.
- Avoid I.M. injections, whenever possible, in patients receiving argatroban to decrease the risk of bleeding.

- Be aware that thrombin times may not be helpful for monitoring argatroban activity because the drug affects all thrombin-dependent coagulation tests.
- Monitor pregnant women during labor and delivery for excessive bleeding or unexpected changes in coagulation parameters. Know that exposure to argatroban may increase the risk of bleeding in the fetus and neonate. Monitor closely.
- Expect dosage to be tapered before stopping to prevent the risk of rebound hypercoagulopathy; drug's effects last only a short time once drug is discontinued.

## PATIENT TEACHING

- Inform patient that argatroban is a blood thinner that's given in the hospital by infusion into a vein. If he needs long-term anticoagulation, he'll be switched to another drug before discharge.
- Advise patient to report immediately any unusual or unexplained bleeding, such as blood in urine, easy bruising, nosebleeds, tarry stools, and vaginal bleeding.
- Instruct patient to avoid injury while receiving argatroban. For example, suggest that he brush his teeth gently, using a soft-bristled toothbrush, and take special care when flossing.

## aripiprazole

**Abilify, Abilify Maintena, Abilify Mycite**

## aripiprazole lauroxil

**Aristada, Aristada Initio**

# Class and Category

*Pharmacologic class:* Atypical antipsychotic

*Therapeutic class:* Antipsychotic

## Indications and Dosages

- *To treat acute schizophrenia; to maintain stability in patients with schizophrenia*

### **SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS (ABILIFY)**

**Adults.** *Initial:* 10 or 15 mg daily. Increased to 30 mg daily, as needed, with dosage adjustments at 2-wk intervals.

**Adolescents.** *Initial:* 2 mg daily for 2 days, then increased to 5 mg daily for 2 days, then increased to 10 mg daily

### **I.M. INJECTION (ABILIFY MAINTENA)**

**Adults.** 400 mg monthly (no sooner than 26 days after last dose) into the deltoid or gluteal muscle. Dosage reduced to 300 mg monthly if adverse reactions occur.

### **I.M. INJECTION (ARISTADA)**

**Adults.** *Initial:* 441, 662, or 882 mg monthly (Administer in the deltoid or gluteal for 441 mg dose; only gluteal for higher doses). Alternatively, 882 mg every 6 wk or 1064 mg every 2 months. Early dosing should not be given sooner than 14 days after the previous injection.

Dosage initiated in one of two ways. *Option 1:* Administer first injection along with one 30 mg oral dose of drug along with one 675 mg injection of Aristada Initio. *Option 2:* Oral drug given for 21 days with first injection.

## **TABLET (ABILIFY MYCITE)**

**Adults.** *Initial:* 10 to 15 mg daily, with dosage increased no sooner than every 2 wk. *Maximum:* 30 mg daily.

- *As adjunct with oral aripiprazole to initiate Aristada treatment for patients with schizophrenia*

## **I.M. INJECTION (ARISTADA INITIO)**

**Adults.** 675 mg as a single dose into the deltoid or gluteal and given at the same time as a 30 mg oral dose of aripiprazole. First dose of Aristada is then administered on the same day or up to 10 days thereafter.

- *To re-initiate treatment with Aristada following a missed dose of Aristada in patients with schizophrenia*

## **I.M. INJECTION (ARISTADA INITIO)**

**Adults taking 441 mg of Aristada.** If time lapse from last dose of Aristada is greater than 6 weeks but less than 7 weeks, 675 mg as a single dose of Aristada Initio given in the deltoid or gluteal.

**Adults taking 662 mg or 882 mg of Aristada.** If time lapse from last dose of Aristada is greater than 8 wks but 12 wks or less, 675 mg as a single dose of Aristada Initio given into the deltoid or gluteal.

**Adults taking 1064 mg of Aristada.** If time lapse from last dose of Aristada is greater than 10 wks but 12 weeks or less, 675 mg as a single dose of Aristada Initio into the deltoid or gluteal.

## **I.M. INJECTION (ARISTADA INITIO) PLUS ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, OR TABLETS**

**Adults taking 441 mg of Aristada.** If time lapse from last dose of Aristada is greater than 7 wks, 675 mg given into the deltoid or gluteal as a single dose of Aristada Initio plus a single 30 mg oral dose of aripiprazole.

**Adults taking 662 mg, 882 mg, or 1064 mg of Aristada.** If time lapse from last dose of Aristada is greater than 12 wks, 675 mg as a single dose of Aristada Initio given into the deltoid or gluteal plus a single 30 mg oral dose of aripiprazole.

- *To treat acute manic and mixed episodes in bipolar I disorder with or without psychotic features; to maintain stability in patients with bipolar I disorder; as adjunct with lithium or valproate in patients with bipolar I disorder*

## **ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS (ABILIFY)**

**Adults.** *Initial:* 15 mg daily (10 to 15 mg if lithium or valproate coadministered), increased to 30 mg daily, as needed. *Maintenance:* 15 to 30 mg daily. *Maximum:* 30 mg daily.

**Children ages 10 to 17.** *Initial:* 2 mg daily, increased after 2 days to 5 mg daily and then after 2 days to 10 mg daily. Increased in 5-mg increments, as needed, at 2-wk intervals. *Maintenance:* Lowest dose possible to maintain remission. *Maximum:* 30 mg daily.

## **TABLETS (ABILIFY MYCITE)**

**Adults with acute and mixed episodes of bipolar I disorder.** *Initial:* 15 mg once daily. *Maximum:* 30 mg daily.

**Adults with bipolar I disorder receiving adjunct treatment with lithium or valproate.** *Initial:* 10 to 15 mg once daily. *Maximum:* 30 mg daily.

- *To maintain stability with monotherapy treatment of bipolar I disorder*

## **I.M. INJECTION (ABILIFY MAINTENA)**

**Adults.** 400 mg monthly (no sooner than 26 days after the previous injection) into the deltoid or gluteal. Dosage reduced to 300 mg monthly if adverse reactions occur.

- *As adjunct to treat depression in patients already taking an antidepressant*

## **ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS (ABILIFY)**

**Adults.** *Initial:* 2 to 5 mg daily, with dosage increased by 5 mg daily at 1-wk intervals. *Maximum:* 15 mg daily.

## **TABLETS (ABILIFY MYCITE)**

**Adults.** *Initial:* 2 to 5 mg daily, increased as needed, no less than once a wk. *Maximum:* 15 mg daily.

- *To treat irritability associated with autistic disorder*

## **ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS (ABILIFY)**

**Children ages 6 to 17.** *Initial:* 2 mg daily, with dosage increased after 1 wk to 5 mg daily and then after 1 wk to 10 mg daily and then after 1 wk to 15 mg daily, as needed.

- *To treat Tourette's disorder*

## **ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS (ABILIFY)**

**Children ages 6 to 18 weighing 50 kg (110 lb) or more.** *Initial:* 2 mg daily for 2 days, then 5 mg daily for 5

days, followed by dosage increased to 10 mg daily on day 8. Dosage increased 5 mg daily at weekly intervals, as needed, to control tics. *Maximum*: 20 mg daily.

**Children age 6 to 18 weighing less than 50 kg (110 lb).** *Initial*: 2 mg daily for 2 days, with dosage increased to 5 mg daily on day 3. Dosage increased gradually weekly, as needed, to control tics. *Maximum*: 10 mg daily.

➤ *To treat agitation associated with bipolar mania or schizophrenia*

## **I.M. INJECTION (ABILIFY)**

*Adults.* 5.25 to 9.75 mg, repeated, as needed, after 2 or more hr. *Maximum*: Cumulative daily doses up to 30 mg with dosing intervals of 2 hr or more.

**DOSAGE ADJUSTMENT** Aristada Initio administration avoided in patients who are known CYP2D6 poor metabolizers or in patients taking strong CYP2D6 or CYP3A4 inhibitors or strong CYP3A4 inducers because dosage adjustment cannot be made as product is only available in a single strength. For other aripiprazole products, dosage reductions made for patients who are known CYP2D6 poor metabolizers and patients taking concomitant CYP2D6 inhibitors, CYP3A4 inhibitors, and/or CYP3A4 inducers for more than 14 days. Dosage reduction individualized taking into account current dosage prescribed and type of aripiprazole formulation being used. Dosage of Abilify formulation doubled over 1 to 2 weeks for patients taking strong CYP3A4 inducers such as carbamazepine or rifampin.

## **Mechanism of Action**

May produce antipsychotic effects through partial agonist and antagonist actions. Aripiprazole acts as a partial agonist at dopamine (especially D<sub>2</sub>) receptors and

serotonin (especially 5-HT<sub>1A</sub>) receptors. The drug acts as an antagonist at 5-HT<sub>2A</sub> serotonin receptor sites.

## Contraindications

Hypersensitivity to aripiprazole or its components

## Interactions

### DRUGS

*antihypertensives*: Possibly enhanced antihypertensive effects

*benzodiazepines such as lorazepam*: Increased risk of orthostatic hypotension and sedation

*strong CYP3A4 inducers such as carbamazepine, rifampin*: Possibly increased clearance and decreased blood level of aripiprazole

*strong CYP3A4 inhibitors such as clarithromycin, itraconazole; strong CYP2D6 inhibitors such as fluoxetine, quinidine, paroxetine*: Increased exposure of aripiprazole and increased risk of adverse reactions

### ACTIVITIES

*alcohol use*: Increased CNS depression

## Adverse Reactions

**CNS**: Abnormal gait, aggression, agitation, akathisia, anxiety, asthenia, catatonia, cognitive and motor impairment, confusion, **CVA (elderly)**, delusions, depression, dizziness, dream disturbances, dystonia, extrapyramidal reactions, fatigue, fever, hallucinations, headache, **homicidal ideation**, hostility, insomnia,

**intracranial hemorrhage**, lethargy, light-headedness, mania, nervousness, **neuroleptic malignant syndrome**, paranoia, Parkinsonism, restlessness, schizophrenic reaction, **seizures**, sleep walking, somnolence, **suicidal ideation**, tardive dyskinesia, transient ischemic attack (elderly), tremor

**CV:** Angina pectoris, **arrhythmias**, **bradycardia**, **cardiopulmonary arrest**, chest pain, **circulatory collapse**, **deep vein thrombosis**, dyslipidemia, elevated serum CK levels, **heart failure**, hyperlipidemia, hypertension, **MI**, orthostatic hypotension, palpitations, peripheral edema, **prolonged QT interval**, tachycardia

**EENT:** Blurred vision, conjunctivitis, diplopia, dry mouth, increased salivation, **laryngospasm**, nasal congestion, nasopharyngitis, **oropharyngeal spasm**, pharyngitis, photophobia, rhinitis, sinusitis

**ENDO:** Breast pain, gynecomastia, hyperglycemia, diabetes mellitus

**GI:** Abdominal discomfort, constipation, decreased appetite, diarrhea, difficulty swallowing, **GI bleeding**, gastroesophageal reflux disease, **hepatitis**, hiccups, indigestion, jaundice, nausea, vomiting

**GU:** Decreased or increased libido, erectile dysfunction, menstrual disorders, nocturia, priapism, **renal failure**, urinary incontinence or retention

**HEME:** **Agranulocytosis**, anemia, **leukopenia**, **neutropenia**, **thrombocytopenia**

**MS:** Arthralgia, joint stiffness, muscle spasms or weakness, musculoskeletal pain, myalgia, neck and limb rigidity, **rhabdomyolysis**, trismus

**RESP:** Apnea, aspiration, asthma, cough, dyspnea, pneumonia, pulmonary edema or embolism, respiratory failure

**SKIN:** Alopecia, diaphoresis, dry skin, ecchymosis, photosensitivity, pruritus, rash, ulceration, urticaria

**Other:** Anaphylaxis; angioedema; dehydration; elevated blood creatine phosphokinase (Aristada); flu-like symptoms; heat stroke; injection-site induration, pain, redness, swelling (Aristada); hypokalemia; hyponatremia; intense uncontrollable urges to perform certain activities, such as gambling and sexual acts; weight gain

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-961-2388 or <http://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/>.
- Drug may cause fetal harm. Neonates exposed to drug during the third trimester of pregnancy are at risk for extrapyramidal and withdrawal symptoms.
- Use with caution only if benefit to mother outweighs potential risk to fetus and no other alternative is available.

### LACTATION

- Drug is present in human milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential adverse reactions in the breastfed infant.

## Nursing Considerations

- Know that aripiprazole shouldn't be used to treat dementia-related psychosis in the elderly because of an increased risk of death.
- Use cautiously in patients with cardiovascular disease, cerebrovascular disease, or conditions that would predispose them to hypotension. Also use cautiously in those with a history of seizures or with conditions that lower the seizure threshold, such as Alzheimer's disease.
- Use cautiously in elderly patients because of increased risk of serious adverse cerebrovascular effects, such as stroke and transient ischemic attack.
- Know that you may give oral solution on a milligram-per-milligram basis in place of tablets up to 25 mg.
- Be aware that for patients who have never taken aripiprazole, tolerability must be established with oral form prior to initiating parenteral therapy. After first dose of Abilify Maintena, expect to continue to administer oral aripiprazole (10 to 20 mg) for 14 consecutive days to achieve a therapeutic level during the initiation of the intramuscular injection.
- Be aware that Abilify Maintena comes in two types of kits: prefilled chamber syringe or single-use vials.
- Reconstitute Abilify Maintena lyophilized powder in prefilled dual-chamber syringe by pushing plunger rod slightly to engage threads. Then rotate plunger rod until the rod stops rotating to release diluent. After plunger rod is at a complete stop, middle stopper will be at the indicator line. Vertically shake the syringe vigorously for 20 seconds until drug is uniformly milky white.
- Reconstitute Abilify Maintena using single-use vials by using the syringe with the preattached needle to withdraw the predetermined volume from the vial into the syringe. Slowly inject the into the vial containing the lyophilized powder. Withdraw air to equalize the pressure, then remove the needle from the vial. Engage the needle safety device by using the one-handed technique. Gently press the sheath against a flat surface until the needle is firmly engaged in the needle protection sheath and discard appropriately. Shake the vial vigorously for 30 seconds until the reconstituted suspension appears uniform. It should be opaque and milky-white in color. If the injection is not given immediately after reconstitution, keep the vial at room temperature and shake the vial vigorously for at least 60 seconds to resuspend prior to administration. Do not store the reconstituted suspension in a syringe.
- Prepare Abilify Maintena prior to injection after reconstituting from a single-use vial by removing cover from the vial adapter package but do not remove the vial adapter from the package. Using the vial adapter package to handle the vial adapter, attach the prepackaged BD Luer-Lok

syringe to the vial adapter. Use the syringe to remove the vial adapter from the package and discard the vial adapter package. Do not touch the spike tip of the adapter at any time. Determine the recommended volume for injection using the manufacturer chart for size vial being used and dosage prescribed. After wiping top of vial with a sterile alcohol swab, place and hold the vial of the reconstituted suspension on a hard surface. Attach the adapter-syringe assembly to the vial by holding the outside of the adapter and pushing the adapter's spike firmly through the rubber stopper until the adapter snaps in place. Slowly withdraw the recommended volume from the vial into the syringe.

- Inject Abilify Maintena form slowly, deep into the deltoid or gluteal muscle, and never I.V. or subcutaneously. Do not massage the injection site.
- Use the following guide for determining when to administer missed doses of the long-acting formulation, Abilify Maintena. If a second or third dose is missed and it's been more than 4 weeks but less than 5 weeks since the last injection, administer the injection as soon as possible. If more than 5 weeks have elapsed since the last injection, restart concomitant oral aripiprazole, as ordered, for 14 days with the next administered injection. If a fourth or subsequent doses are missed and it's been more than 4 weeks but less than 6 weeks since the last injection, administer the injection as soon as possible. If more than 6 weeks have elapsed since the last injection, restart concomitant oral aripiprazole, as ordered, for 14 days with the next administered injection.
- Prepare Aristada for injection by first tapping the syringe at least 10 times and then shaking syringe vigorously for 30 seconds to ensure a uniform suspension. If pen is not used within 15 minutes, shake again for 30 seconds. Select needle length based on injection site and attach to syringe. Prime the syringe to remove air.
- Administer Aristada formulation into the gluteal muscle by I.M. injection only for all dosages except the 441-mg dose, which may also be administered into the deltoid muscle. Inject in a rapid and continuous manner in less than 10 seconds.
- Follow manufacturer guidelines when a dose of Aristada is missed which is based upon the dosage missed and length of time that has elapsed. However, be aware that Aristada Initio may be used to reinitiate treatment with Aristada.
- Prepare Aristada Initio for injection in the same manner as Aristada. Administer Aristada Initio into the deltoid muscle using a 21-gauge, 1-inch or 20-gauge, 1½-inch needle or into the gluteal muscle using a 20-gauge, 1½-inch or 20-gauge, 2-inch needle. Avoid overtightening the needle when attaching to syringe because needle hub may crack. Inject in a rapid and continuous manner intramuscularly. Do not inject by any other route.

- Be aware that Abilify Mycite is a drug-device combination product comprised of aripiprazole tablets embedded with an ingestible event marker (IEM) sensor intended to track drug ingestion. Other ways used to track ingestion of aripiprazole include a Mycite patch, which is a wearable sensor that detects signals from the IEM sensor after ingestion of aripiprazole and transmits data to a smartphone. Alternatively, there is a Mycite app, which is a smartphone application, which is used with a compatible smartphone to display information for the patient and web-based portal for healthcare professionals and caregivers to track compliance.
- Know that most ingestions can be tracked with Abilify Mycite within 30 minutes, but it may take up to 2 hours for the smartphone app and web portal to detect that the tablet has been taken.
- When administering Abilify Mycite in tablet form, have patient swallow tablets whole; do not have him chew tablets and do not crush or divide tablets.
- Apply the Abilify Mycite patch to the left side of the body just above the lower edge of the rib cage. Do not place it in areas where the skin is cracked, inflamed, irritated, or scraped or in a location that overlaps the area of the most recently removed patch. Be aware that the patch must be removed before patient undergoes an MRI.
- Monitor patient for difficulty swallowing or excessive somnolence, which could predispose to accidental injury or aspiration. For patients with medical conditions or who are taking medications that could exacerbate CNS effects, complete a fall risk assessment and institute safety measures.

**WARNING** Be aware that aripiprazole rarely may cause neuroleptic malignant syndrome, seizures, and tardive dyskinesia. Monitor patient closely throughout therapy, and take safety precautions as needed. Be aware that tardive dyskinesia may resolve, partially or completely, if aripiprazole is discontinued.

- Watch patients closely (especially children, adolescents, and young adults) for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times.
- Monitor patient's CBC, as ordered, because serious adverse hematologic reactions may occur, such as agranulocytosis, leukopenia, and neutropenia. Assess more often during first few months of therapy if

patient has a history of drug-induced leukopenia or neutropenia or a significantly low WBC count. If abnormalities occur during therapy, watch for fever or other signs of infection, notify prescriber and, if severe, expect drug to be stopped.

- Monitor patient's weight, blood glucose level, and lipid levels, as ordered, because atypical antipsychotic drugs such as aripiprazole may cause metabolic changes. If patient is already a diabetic, monitor blood glucose levels more closely.

## **PATIENT TEACHING**

- Instruct patient prescribed orally disintegrating tablets to open the blister pack only when ready to take the tablet. Tell him to peel back the foil carefully and not to push tablet through the foil because doing so could damage the tablet. Tell him to place the tablet on his tongue without breaking it and let it dissolve. If needed, he may take a drink.
- Instruct patient how to use the Abilify Mycite system. If taking drug orally, tell patient to swallow tablets whole and not to chew, crush, or divide them. If using the patch, tell patient to keep patch on when exercising, showering, and swimming. Tell patient the patch will have to be changed at least weekly. Inform patient that the app will prompt patient to change the patch and will direct patient on how to apply and remove the patch correctly. Inform patient that if undergoing an MRI, the patch must be removed and a new one applied after the test. Advise patient that if skin irritation occurs, he should remove the patch and notify prescriber.
- Advise patient to get up slowly from a lying or sitting position during aripiprazole therapy to minimize orthostatic hypotension.
- Urge patient to avoid alcohol during aripiprazole therapy.
- Instruct patient to avoid hazardous activities until drug's effects are known. Also, alert patient and family of increased risk for falls, especially if patient has other medical conditions or takes medication that may affect the nervous system.
- Urge patient to avoid activities that raise body temperature suddenly, such as strenuous exercise and exposure to extreme heat, and to compensate for situations that cause dehydration, such as vomiting or diarrhea.
- Instruct patient and caregivers to notify prescriber about intense urges, such as for gambling or sex, because dosage may need to be reduced or drug discontinued.

- Instruct patient to inform all prescribers of any drugs he's taking, including OTC drugs, because of risk of interactions.
- Advise female patient of childbearing age to notify prescriber if she intends to become or suspects that she is pregnant during therapy.
- Instruct diabetic patient to monitor blood glucose levels closely, especially if taking the oral solution form because each milliliter of solution contains 400 mg of sucrose and 200 mg of fructose.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes, and particularly if patient is a child, teenager, or young adult.

## armodafinil

### Nuvigil

## Class and Category

*Pharmacologic class:* Analeptic modafinil derivative

*Therapeutic class:* CNS stimulant

*Controlled substance schedule:* IV

## Indications and Dosages

- *To treat narcolepsy or as adjunct to standard therapy for excessive daytime sleepiness in obstructive sleep apnea/hypopnea syndrome*

### **TABLETS**

**Adults.** 150 or 250 mg once daily in the morning.

- *To improve daytime wakefulness in patients with excessive sleepiness from circadian rhythm disruption*

*(shift-work sleep disorder)*

## **TABLETS**

**Adults.** 150 mg once daily about 1 hr before start of work shift.

***DOSAGE ADJUSTMENT*** Dosage decreased for patients who are elderly or have severe hepatic impairment.

Route	Onset	Peak	Duration
P.O.	Unknown	2 hr (fasting) 4–6 hr (with food)	Unknown

## **Mechanism of Action**

May produce CNS-stimulant effects by binding to dopamine transporter in the brain and inhibiting dopamine reuptake in limbic regions. These actions increase alertness and reduce drowsiness and fatigue.

## **Contraindications**

Hypersensitivity to armodafinil, modafinil, or their components

## **Interactions**

### **DRUGS**

*cyclosporine:* Possibly decreased blood cyclosporine level and increased risk of organ transplant rejection

*CYP2C19 substrates such as clomipramine, diazepam, omeprazole, and propranolol:* Possibly prolonged elimination time and increased blood levels of these drugs

*CYP3A4/5 substrates such as midazolam, triazolam:*

Possibly decreased effectiveness of these drugs

*fosphenytoin, mephenytoin, phenytoin:* Possibly decreased effectiveness of armodafinil, increased blood phenytoin level, and increased risk of phenytoin toxicity

*MAO inhibitors:* Increased risk of serious adverse reactions

*oral steroidal contraceptives:* Possibly decreased effectiveness of oral contraceptive and for one month following discontinuation

*warfarin:* Possibly decreased warfarin metabolism and increased risk of bleeding

## **FOODS**

## **ACTIVITIES**

*alcohol use:* Possibly adverse CNS effects

*all foods:* 2- to 4-hr delay for armodafinil to reach peak levels and possibly delayed onset of action

*caffeine:* Increased CNS stimulation

## **Adverse Reactions**

**CNS:** Aggression, agitation, anxiety, attention disturbance, delusions, depression, dizziness, drowsiness, excessive sleepiness, fatigue, fever, hallucinations, headache (including migraine), insomnia, irritability, mania, nervousness, paresthesia, **suicidal ideation**, thirst, tremor

**CV:** Increased heart rate, palpitations

**EENT:** Dry mouth, mouth sores

**GI:** Abdominal pain (upper), anorexia, constipation, diarrhea, dyspepsia, loose stools, nausea, vomiting

**GU:** Polyuria

**RESP:** Bronchospasm, dyspnea

**SKIN:** Contact dermatitis, Stevens-Johnson syndrome, toxic epidermal necrolysis

**Other:** Anaphylaxis, angioedema, drug reaction with eosinophilia and system symptoms (DRESS), flu-like illness

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-404-4106.
- Limited data suggests drug may cause fetal harm.
- Intrauterine growth restriction and spontaneous abortion have been reported in association with drug.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### REPRODUCTION

- Use of oral hormonal contraceptives can be reduced during drug therapy. Women of childbearing age using this type of contraception should use an additional barrier or alternative nonhormonal type of contraception during drug therapy and for 1 month after drug is discontinued.

## Nursing Considerations

- Know that armodafinil shouldn't be given to patients with mitral valve prolapse syndrome or a history of left ventricular hypertrophy because drug may cause ischemic changes.

**WARNING** Know whether patient has a history of alcoholism, stimulant abuse, or other substance abuse, and ensure compliance with armodafinil therapy. Watch for signs of misuse or abuse, including frequent prescription refill requests, increased frequency of dosing, and drug-seeking behavior. Also watch for evidence of excessive armodafinil use, including agitation, anxiety, diarrhea, nausea, nervousness, palpitations, sleep disturbances, and tremor.

- Know that armodafinil, like other CNS stimulants, may alter mood, perception, thinking, judgment, feelings, and motor skills and may produce signs that patient needs sleep.
- Giving drug to patient with a history of psychosis, emotional instability, or psychological illness with psychotic features may require a baseline behavioral assessment or frequent clinical observation.
- Stop drug at first sign of rash, and notify prescriber. Although rare, rash may indicate a potentially life-threatening event.
- Monitor patient for signs and symptoms of multisystem organ hypersensitivity, such as may require a fever, hematologic abnormalities, hepatitis, myocarditis, pruritus, rash, or any other serious abnormality because multiorgan hypersensitivity may vary in its presentation. While multisystem organ hypersensitivity has only occurred with modafinil, the possibility that it may occur with armodafinil cannot be ruled out because the two drugs are very closely related. Therefore, if suspected, notify prescriber immediately, expect to discontinue drug, and provide supportive care, as ordered.
- Watch closely for suicidal tendencies, especially in patients with a psychiatric history.

## **PATIENT TEACHING**

- Inform patient that armodafinil can help, but not cure, narcolepsy and that drug's full effects may not be seen right away.
- Advise patient to avoid taking armodafinil within 2 hours of eating because food may delay time to peak drug effect and onset of action. If patient drinks grapefruit juice, encourage him to drink a consistent amount daily.

**WARNING** Tell patient to stop taking armodafinil immediately and seek emergency medical treatment if he experiences an allergic reaction such as difficulty breathing or swallowing; hives; or swelling of eyes, face, lips, or tongue.

- Inform patient that drug can affect his concentration and ability to function and can hide signs of fatigue. Urge him not to drive or perform activities that require mental alertness until drug's full CNS effects are known.
- Instruct patient to continue previously prescribed treatments such as CPAP and not to stop without consulting prescriber first.
- Tell patient to contact prescriber immediately if she begins to experience psychiatric symptoms such as anxiety, depression, or signs of mania or psychosis.
- Advise patient to avoid alcohol with armodafinil because drug may decrease alertness.
- Encourage a regular sleeping pattern.
- Caution patient to avoid excessive intake of foods, beverages, and OTC drugs that contain caffeine because caffeine may lead to increased CNS stimulation.
- Advise patient to report the presence of blisters, mouth sores, peeling, or rash immediately to prescriber and to stop taking armodafinil. Also encourage patient to report any unusual or persistent signs and symptoms to prescriber.
- Inform woman that armodafinil can decrease effectiveness of certain contraceptives, including birth control pills and implantable hormonal contraceptives. If she uses such contraceptives, urge her to use an alternate birth control method during armodafinil therapy and for up to 1 month after it stops. Tell patient to notify prescriber if pregnancy is suspected or occurs and encourage her to notify the pregnancy exposure registry.
- Instruct patient to notify prescriber before taking any new medication, including over-the-counter preparations.
- Urge family or caregiver to watch patient closely for abnormal behaviors, including suicidal tendencies, especially if patient has a psychiatric history.

- Advise patient to keep follow-up appointments with prescriber so that her progress can be monitored.

## asenapine

**Saphris, Secuado**

### Class and Category

*Pharmacologic class:* Dopamine-serotonin antagonist

*Therapeutic:* Atypical antipsychotic

### Indications and Dosages

➤ *To treat schizophrenia*

#### SUBLINGUAL TABLETS

**Adults.** *Initial:* 5 mg twice daily, increased to 10 mg twice daily after 1 wk, if needed and tolerated. *Maximum:* 10 mg twice daily.

#### TRANSDERMAL (SECUADO)

**Adults.** *Initial:* 3.8 mg/24 hr, increased to 5.7 mg/24 or 7.6/24 hr, if needed and tolerated.

➤ *To treat manic or mixed episodes associated with bipolar I disorder as monotherapy*

#### SUBLINGUAL TABLETS

**Adults.** 5 to 10 mg twice daily and then if 5 mg dose is used it may be increased to 10 mg, if needed and tolerated.

*Maximum:* 10 mg twice daily.

**Children age 10 and over.** *Initial:* 2.5 mg twice daily increased after 3 days to 5 mg twice daily and after an additional 3 days to 10 mg twice daily, as needed and tolerated. *Maximum:* 10 mg twice daily.

- *To provide maintenance monotherapy in adults in the treatment of bipolar I disorder*

## SUBLINGUAL TABLETS

**Adults.** 5 or 10 mg twice daily, whichever dosage patient was stabilized on. Then dosage decreased, if needed. *Maximum:* 10 mg twice daily.

- *As adjunct therapy with lithium or valproate to treat bipolar I disorder*

**Adults.** *Initial:* 5 mg twice daily, increased to 10 mg twice daily, as needed. *Maximum:* 10 mg twice daily.

***DOSAGE ADJUSTMENT*** Dosage may be decreased to 5 mg twice daily if adverse reactions occur.

Route	Onset	Peak	Duration
P.O.	Unknown	30-90 min	Unknown

## Mechanism of Action

May produce antipsychotic effects through antagonist actions at dopamine receptors, especially D<sub>2</sub>, and serotonin receptors, especially 5-HT<sub>2A</sub>.

## Contraindications

Hypersensitivity to asenapine or its components, severe hepatic impairment

# Interactions

## DRUGS

*antihypertensives, CNS depressants*: Possibly enhanced effects

*class I A and III antiarrhythmics, gatifloxacin, moxifloxacin, other antipsychotic drugs*: Increased risk of prolonged QT interval

*paroxetine*: Possibly increased paroxetine effect

## ACTIVITIES

*alcohol use*: Possibly enhanced effect

# Adverse Reactions

**CNS**: Agitation, akathisia, anger, anxiety, depression, dizziness, dyskinesia, dystonia, extrapyramidal symptoms, fatigue, fever, gait disturbance, headache, hyperkinesia, insomnia, irritability, mania, masked facies, **neuroleptic malignant syndrome**, Parkinsonism, **seizures**, somnolence, **suicidal ideation**, syncope, tardive dyskinesia, torticollis, tremor

**CV**: Hyperlipidemia, hypertension, orthostatic hypotension, peripheral edema, **prolonged QT interval**, tachycardia, temporary bundle branch block

**EENT**: Accommodation disorder; blepharospasm; blurred vision; **choking**; diplopia; dry mouth; nasopharyngitis; nasal congestion; oral hypoesthesia or paraesthesia; salivary hypersecretion; sublingual application-site reactions such as blisters, inflammation, oral ulcers, peeling, or sloughing; oropharyngeal pain; swollen tongue; taste perversion; toothache

**ENDO:** Hyperglycemia, diabetes mellitus, hyperprolactinemia

**GI:** Abdominal pain, constipation, dyspepsia, dysphagia, elevated liver enzymes, gastroesophageal reflux disease, increased appetite, stomach discomfort, vomiting

**GU:** Dysmenorrhea, enuresis (children)

**HEME:** Anemia, **leukopenia**, **neutropenia**, **thrombocytopenia**

**MS:** Arthralgia, dysarthria, extremity pain, muscle rigidity, myalgia

**RESP:** Dyspnea

**SKIN:** Photosensitivity reaction

**Other:** **Anaphylaxis**, **angioedema**, dehydration, elevated creatine kinase, **hyponatremia**, weight gain

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-961-2388 or <http://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/>.
- Drug may cause fetal harm.
- Neonates exposed to drug during the third trimester of pregnancy are at risk for extrapyramidal and withdrawal symptoms.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Avoid asenapine in patients with a history of cardiac arrhythmias; conditions that might prolong the QT interval, such as bradycardia, hypokalemia, or hypomagnesemia; or congenital QT-interval prolongation because of increased risk of torsades de pointes or sudden death.
- Know that asenapine shouldn't be used for dementia-related psychosis in elderly patients because of an increased risk of death.
- Use cautiously in patients with mild to moderate hepatic impairment.
- Use cautiously in patients with a history of seizures or who have conditions that may lower the seizure threshold, such as Alzheimer's dementia, because drug increases risk of seizures in these patients.

**WARNING** Monitor patient closely even with the first dose for life-threatening hypersensitivity reactions that may include anaphylaxis and angioedema.

- Monitor elderly patients with psychosis closely for adverse effects because asenapine drug exposure has been found to be higher in these patients than in younger adult patients.
- Monitor patient's blood glucose level, lipid levels and weight, as ordered, because atypical antipsychotic drugs such as asenapine may cause metabolic changes. If patient is already diabetic, monitor blood glucose levels more closely.
- Know that the smallest dose of asenapine and the shortest duration of treatment should be used to minimize the risk of the patient developing tardive dyskinesia, which may become irreversible. If signs and symptoms appear, notify the prescriber, and know that the drug may need to be discontinued.

**WARNING** Know that asenapine rarely may cause neuroleptic malignant syndrome or tardive dyskinesia. Monitor patient closely throughout therapy, and take safety precautions as needed. Expect to stop drug if any of these adverse effects occur.

- Monitor patient's CBC regularly, as ordered. Notify prescriber of any change because drug may need to be stopped.

- Monitor patient for trouble swallowing or excessive somnolence, which could predispose him to aspiration, choking, or injury.

## **PATIENT TEACHING**

- Tell patient to remove tablet from package only when ready to take it and to use dry hands. Tell him to firmly press and hold thumb button, and then pull out tablet pack from case. Then, he should peel back the colored tab, being careful not to push tablet through the tab because doing so could damage tablet. Instruct patient to place tablet under his tongue and let it dissolve completely. Tell him to then slide tablet pack back into case until it clicks.
- Caution patient not to crush, chew, or swallow tablets.
- Advise him not to eat or drink for at least 10 minutes after taking oral asenapine.
- Inform patient that application-site reactions may occur in the sublingual area, which may include blisters, inflammation, oral ulcers, peeling, or sloughing of tissue. Also inform patient that numbness or tingling of his mouth or throat may occur after administration of asenapine, but that it usually resolves within 1 hour.
- Teach patient how to apply the transdermal system if prescribed. Tell patient each system is to be worn for 24 hours only and only one system should be worn at any one time. Instruct patient to apply to a clean, dry, and intact skin area on the abdomen, hip, or upper arm or back. The system should be applied to a different application site each time a new system is applied. Caution the patient not to cut open the pouch until ready to apply nor should the patient cut the system in any way. Tell patient if the system lifts at the edges to reattach by pressing firmly and smoothing down the edges. However, if it comes off, a new system should be applied.
- Tell patient using the transdermal system to discard each used system by folding it so the adhesive side sticks to itself and then discard. Advise patient if burning or irritation occurs, the system should be removed and a new one applied in a different site. Although patient may shower, inform the patient that it is not known if swimming or taking a bath is safe. Caution patient not to apply external heat sources over the system.
- Teach patient the signs and symptoms of a serious allergic reaction and to seek immediate emergency treatment if present. Also inform patient of other serious adverse reactions and tell patient to report any persistent, severe, or unusual effects to prescriber immediately, including abnormal movements.

- Urge patient to avoid alcohol while taking asenapine.
- Instruct diabetic patient taking asenapine to monitor blood glucose levels closely because hyperglycemia may occur.
- Advise patient to get up slowly from lying or sitting position during asenapine therapy to minimize orthostatic hypotension.
- Caution patient to avoid hazardous activities until drug's effects are known. Also, alert patient and family of increased risk for falls, especially if patient has other medical conditions or takes medication that may affect the nervous system.
- Urge patient to avoid activities that raise body temperature suddenly, such as strenuous exercise and exposure to extreme heat, and to compensate for situations that cause dehydration, such as vomiting or diarrhea.
- Tell patient that if he has a preexisting low WBC or a history of drug-induced low WBC, he should have her CBC monitored throughout asenapine therapy.
- Inform prescriber of any new medication being prescribed or use of any over-the-counter drugs.
- Advise female patient of childbearing age to notify prescriber if she intends to become or suspects that she is pregnant during therapy, because drug may affect the fetus. Inform her that if she does become pregnant she should contact the pregnancy registry.

## aspirin

(acetylsalicylic acid, ASA)

**Ancasal (CAN), Arthrinol (CAN), Arthritis (CAN), Aspir-81, Aspirin, Aspir-Low, Atria S.R. (CAN), Bayer, Durlaza, Easprin, Ecotrin, Empirin, Genprin, Miniprin, Norwich,**

**Novasen (CAN), Sal-Adult (CAN),  
Sal-Infant (CAN), St. Joseph  
Children's, Supasa (CAN), Zorprin**

## **Class and Category**

*Pharmacologic class:* Salicylate

*Therapeutic class:* NSAID (anti-inflammatory, antiplatelet, antipyretic, nonopioid analgesic)

## **Indications and Dosages**

- *To relieve mild pain or fever*

**CHEWABLE TABLETS, CONTROLLED-RELEASE TABLETS, ENTERIC-COATED TABLETS, SOLUTION, TABLETS, TIMED-RELEASE TABLETS, SUPPOSITORIES**

**Adults and adolescents.** 325 to 650 mg every 4 hr, as needed; or 500 mg every 3 hr, as needed; or 1,000 mg every 6 hr, as needed. *Maximum:* 4,000 mg daily.

**Children ages 2 to 14.** 10 to 15 mg/kg/dose every 4 hr, as needed, up to 80 mg/kg daily.

- *To relieve mild to moderate pain from inflammation, as in rheumatoid arthritis and osteoarthritis*

**CHEWABLE TABLETS, CONTROLLED-RELEASE TABLETS, ENTERIC-COATED TABLETS, SOLUTION, TABLETS, TIMED-RELEASE TABLETS, SUPPOSITORIES**

**Adults and adolescents.** 3 g daily in divided doses.

- *To treat juvenile rheumatoid arthritis*

## **CHEWABLE TABLETS, CONTROLLED-RELEASE TABLETS, ENTERIC-COATED TABLETS, SOLUTION, TABLETS, TIMED-RELEASE TABLETS, SUPPOSITORIES**

**Children.** 90 to 130 mg/kg daily in divided doses every 6 to 8 hr.

- *To reduce the risk of recurrent transient ischemic attacks or ischemic stroke*

**Adults.** 50 to 325 mg once daily.

- *To reduce the severity of or prevent acute MI*

## **TABLETS**

**Adults. Initial:** 160 to 325 mg as soon as MI is suspected.

**Maintenance:** 160 to 325 mg daily for 30 days.

- *To reduce risk of MI in patients with previous MI or unstable angina*

## **TABLETS**

**Adults.** 75 to 325 mg daily.

- *To reduce the risk of death and MI in patients with chronic coronary artery disease; to reduce risk of death and recurrent stroke in patients who have had an ischemic stroke or transient ischemic attack*

## **E.R. CAPSULES (DURLAZA)**

**Adults.** 162.5 mg once daily.

- *To prepare patient for carotid endarterectomy*

## TABLETS

**Adults.** 80 mg once daily to 650 mg twice daily, started presurgery.

- *Adjunct therapy with coronary artery bypass graft*

## TABLETS

**Adults.** 75 to 325 mg daily starting 6 hr after procedure and continued for 1 yr.

- *Adjust treatment for percutaneous transluminal coronary angioplasty*

Route	Onset	Peak	Duration
P.O. (chewable tablets)	Rapid	Unknown	1-4 hr
P.O. (controlled- release)	5-30 min	1-4 hr	4-6 hr
P.O. (enteric- coated)	5-30 min	Unknown	1-4 hr
P.O. (solution)	5-30 min	15-40 min	1-4 hr
P.O. (tablets)	15-30 min	1-2 hr	4-6 hr
P.O. (timed- release)	5-30 min	1-4 hr	4-6 hr
P.R.	Unknown	Unknown	4-6 hr

## TABLETS

**Adults.** 325 mg 2 to 3 hr before procedure, then 160 to 325 mg daily.

- *To treat spondyloarthropathies*

## TABLETS

**Adults.** Up to 4 g daily in divided doses.

## Mechanism of Action

Blocks the activity of cyclooxygenase, the enzyme needed for prostaglandin synthesis. Prostaglandins, important mediators in the inflammatory response, cause local vasodilation with swelling and pain. With blocking of cyclooxygenase and inhibition of prostaglandins, inflammatory symptoms subside. Pain is also relieved because prostaglandins play a role in pain transmission from the periphery to the spinal cord. Aspirin inhibits platelet aggregation by interfering with production of thromboxane A<sub>2</sub>, a substance that stimulates platelet aggregation. Aspirin acts on the heat-regulating center in the hypothalamus and causes peripheral vasodilation, diaphoresis, and heat loss.

## Contraindications

Active bleeding or coagulation disorders; breastfeeding (continuous high dose); fever, chickenpox or flu-like symptoms in children and teens; current or recent GI bleed or ulcers; hypersensitivity to aspirin, aspirin products, other NSAIDs, tartrazine dye, or their components; third trimester of pregnancy

## Interactions

### DRUGS

*ACE inhibitors; beta blockers:* Decreased antihypertensive effect

*acetazolamide:* Possibly acetazolamide toxicity

*ammonium chloride and other urine acidifiers:* May increase level of aspirin with possibility of aspirin toxicity

*antacids, urine alkalinizers:* Decreased aspirin effectiveness

*anticoagulants, antiplatelets:* Increased risk of bleeding; prolonged bleeding time

*corticosteroids*: Increased excretion and decreased blood level of aspirin

*digoxin*: Increased risk of digitalis toxicity

*diuretics*: Possibly decreased diuretic effectiveness, especially in patients with renal impairment

*heparin*: Increased risk of bleeding

*ibuprofen, naproxen*: Possibly reduced cardioprotective and stroke preventive effects of aspirin

*methotrexate*: Increased blood level and decreased excretion of methotrexate, causing toxicity

*other NSAIDs*: Possibly decreased blood NSAID level and increased risk of adverse GI effects

*oral antidiabetic agents*: Possibly enhanced hypoglycemic effects

*selective serotonin reuptake inhibitors (SSRIs)*: Increased risk of upper gastrointestinal bleeding

*uricosuric agents*: Decreased uricosuric effect

*valproic acid*: Possibly increased valproic acid level and incidence of adverse reactions

## **ACTIVITIES**

*alcohol use*: Increased risk of ulcers

## **Adverse Reactions**

**CNS**: Confusion, **CNS depression**

**EENT**: Hearing loss, tinnitus

**GI**: Diarrhea, **GI bleeding**, heartburn, **hepatotoxicity**, nausea, stomach pain, vomiting

**HEME**: Decreased blood iron level, **leukopenia**, **prolonged bleeding time**, shortened life span of RBCs, **thrombocytopenia**

**RESP:** Bronchospasm

**SKIN:** Ecchymosis, rash, urticaria

**Other:** Angioedema, Reye's syndrome, salicylism (CNS depression, confusion, diaphoresis, diarrhea, difficulty hearing, dizziness, headache, hyperventilation, lassitude, tinnitus, and vomiting) with regular use of large doses

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm especially in the third trimester as drug may cause premature closure of the ductus arteriosus in the fetus.
- Salicylates have also been associated with altered maternal and neonatal hemostasis mechanisms, decreased birth weight, and perinatal mortality.
- Drug is generally not recommended for use during pregnancy. Low dose aspirin (60 to 100 mg daily) may be used sometimes with clotting disorders, recurrent pregnancy loss, or preeclampsia.

### LABOR & DELIVERY

- Drug should not be used 1 week before and during labor and delivery because of the potential for excessive blood loss at delivery.
- Drug may cause prolonged labor.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential adverse reactions in the breastfed infant unless low dose aspirin is prescribed as an antiplatelet.
- If low dose aspirin is used, infant should be monitored for bleeding and bruising.

# Nursing Considerations

- Don't crush timed-release or controlled-release aspirin tablets unless directed.

**WARNING** Use an immediate-release aspirin in situations where a rapid onset of action is required such as in the acute treatment of myocardial infarction or before percutaneous coronary intervention.

- Ask about tinnitus. This reaction usually occurs when blood aspirin level reaches or exceeds maximum dosage for therapeutic effect.

## PATIENT TEACHING

**WARNING** Advise parents not to give aspirin to a child or adolescent with chickenpox or flu symptoms because of risk of Reye's syndrome (rare life-threatening reaction). Tell them to consult prescriber for alternative drugs.

- Advise adult patient taking low-dose aspirin not to also take ibuprofen or naproxen because these drugs may reduce the cardioprotective and stroke preventive effects of aspirin.
- Instruct patient to take aspirin with food or after meals because it may cause GI upset if taken on an empty stomach.
- Advise patient prescribed Durlaza to take the capsule with a full glass of water at the same time every day and to swallow the capsule whole.
- Advise patient to avoid alcohol while taking aspirin to decrease risk of ulcers.
- Instruct patient to stop taking aspirin and notify prescriber if any symptoms of stomach or intestinal bleeding occur such as passage of bloody or tarry stools or if patient is coughing up blood or vomit that looks like coffee grounds.
- Advise patient with tartrazine allergy not to take aspirin.
- Tell patient to consult prescriber before taking aspirin with any prescription drug for blood disorder, diabetes, gout, or arthritis.

- Tell patient not to use aspirin if it has a strong vinegar-like odor.
- Advise pregnant women to check with prescriber before taking aspirin in the third trimester. Likewise, tell breastfeeding mothers to check with prescriber before taking aspirin.

# atazanavir

## Reyataz

### Class and Category

*Pharmacologic class:* Protease inhibitor

*Therapeutic class:* Antiretroviral

### Indications and Dosages

➤ *As adjunct to treat HIV-1 infection*

#### CAPSULES, ORAL POWDER

**Adults who are treatment-experienced.** 300 mg once daily with food in combination with ritonavir 100 mg once daily.

**Adults who are HIV treatment-naïve and cannot tolerate ritonavir.** 400 mg once daily with food.

**Adults who are HIV treatment-naïve and also taking efavirenz, adults who are treatment-experienced and also taking both H2RA and tenofovir DF.** 400 mg once daily with food in combination with ritonavir 100 mg once daily.

**Children ages 13 to 18 who weigh at least 40 kg (88 lb) and are HIV treatment-naïve and cannot tolerate ritonavir.** 400 mg once daily with food.

**Children ages 6 to 18 who weigh at least 35 kg (77 lb).** 300 mg once daily with food in combination with ritonavir 100 mg once daily.

**Children ages 6 to 18 who weigh less than 35 kg (77 lb) but at least 15 kg (33 lb).** 200 mg once daily with food in combination with ritonavir 100 mg once daily.

## **ORAL POWDER**

**Children up to age 6 who weigh less than 25 kg (55 lb) but at least 15 kg (33 lb).** 250 mg once daily with food in combination with ritonavir 80 mg once daily.

**Infants 3 months of age and over who weigh less than 15 kg (33 lb) but at least 5 kg (11 lb).** 200 mg once daily with food in combination with ritonavir 80 mg once daily.

***DOSAGE ADJUSTMENT*** For HIV treatment-experienced pregnant patients who are in the second or third trimester and also being treated with either H2RA or tenofovir DF, atazanavir dosage increased to 400 mg once daily with food and given with ritonavir 100 mg once daily. For HIV treatment-naïve adults with mild hepatic impairment, atazanavir dosage increased to 400 mg once daily and given without ritonavir. For HIV treatment-naïve adults with moderate hepatic impairment, atazanavir dosage kept at 300 mg once daily but given without ritonavir.

## **Mechanism of Action**

Selectively inhibits the virus-specific processing of specific polyproteins in HIV-1-infected cells to prevent formation of mature virions.

## Contraindications

Concurrent therapy with alfuzosin, cisapride, dihydroergotamine, elbasvir/grazoprevir, ergonovine, ergotamine, glecaprevir/pibrentasvir, indinavir, irinotecan, lovastatin, lurasidone, methylergonovine, midazolam (oral), nevirapine, pimozide, rifampin, sildenafil (when used for treatment of pulmonary arterial hypertension), simvastatin, St. John's wort, triazolam; hypersensitivity to atazanavir or any of its components

# Interactions

# DRUGS

*amiodarone, atorvastatin, bepridil, buprenorphine, colchicine, diltiazem, ethinyl and norethindrone, felodipine, fluticasone, ketoconazole, itraconazole, immunosuppressants, lidocaine (systemic) lurasidone, midazolam, nicardipine, nifedipine, norbuprenorphine, PDE5 inhibitors (sildenafil, tadalafil, vardenafil), quetiapine, rifabutin, quinidine, rosuvastatin, salmeterol, trazodone, tricyclic antidepressants, verapamil, voxilaprevir: Increased plasma concentrations of these drugs with possible increased risk of adverse effects that could be serious or life-threatening*

*antacids, buffered medications, efavirenz, H2-receptor antagonists, proton pump inhibitors:* Decreased plasma concentration of atazanavir, decreasing effectiveness

**boceprevir:** Decreased plasma concentrations of both atazanavir and ritonavir when administered together, decreasing effectiveness of both drugs

*bosentan*: Decreased plasma concentration of atazanavir and increased plasma concentration of bosentan

*carbamazepine*: Decreased plasma concentration of atazanavir and increased plasma concentration of carbamazepine, increasing risk of serious carbamazepine-induced adverse reactions

*clarithromycin*: Increased plasma concentration of both atazanavir and clarithromycin, increasing risk of QT prolongation

*didanosine*: Decreased plasma concentration of both atazanavir and didanosine, with decreased effectiveness

*ethinyl estradiol and norgestimate*: Decreased plasma concentration of ethinyl estradiol and increased plasma concentration of norgestimate, possibly affecting contraceptive effectiveness

*lamotrigine*: Possibly decreased plasma concentration of lamotrigine, with increased risk of seizure activity

*other protease inhibitors such as saquinavir*: Possibly increased plasma concentration of protease inhibitor

*phenobarbital, phenytoin*: Decreased plasma concentration of atazanavir, phenobarbital, and phenytoin, decreasing effectiveness and increasing risk of seizures

*ritonavir*: Increased plasma concentration of atazanavir and risk of serious adverse reactions

*tenofovir disoproxil fumarate*: Decreased plasma concentration of atazanavir; increased plasma concentration of tenofovir

*voriconazole*: Decreased plasma concentrations of both atazanavir and voriconazole in patients with a functional CYP2C19 allele; decreased plasma concentration of atazanavir and increased plasma concentration of voriconazole in patients without a functional CYP2C19 allele

*warfarin*: Increased plasma concentration of warfarin, increasing risk of serious or life-threatening bleeding

## **Adverse Reactions**

**CNS:** Depression, dizziness, fever, headache, insomnia, peripheral nervous system abnormalities

**CV:** **Cardiac conduction abnormalities (second- or third-degree AV block, left bundle branch block)**, edema, elevated cholesterol and triglyceride levels, peripheral edema **QT prolongation**

**EENT:** Nasal congestion (children), oropharyngeal pain (children), rhinorrhea (children), scleral icterus

**ENDO:** Diabetes mellitus, fat redistribution, hyperglycemia, **hypoglycemia (children)**

**GI:** Abdominal pain, cholecystitis, cholelithiasis, cholestasis, diarrhea, elevated liver enzymes, **hepatic dysfunction**, hyperbilirubinemia, jaundice, nausea, **pancreatitis**, vomiting

**GU:** **Chronic kidney disease, granulomatous interstitial nephritis, interstitial nephritis**, nephrolithiasis

**HEME:** Decreased hemoglobin or platelet count, **neutropenia**

**MS:** Arthralgia, extremity pain (children), myalgia

**RESP:** Cough (children), wheezing (children)

**SKIN:** Alopecia, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**

**Other:** **Angioedema, drug reaction with eosinophilia and systemic symptoms (DRESS)**, immune

reconstitution syndrome

## **Childbearing Considerations**

### **PREGNANCY**

- Pregnancy exposure registry: 1-800-258-4263.
- Drug has potential to increase risk for hyperbilirubinemia and lactic acidosis syndrome in mother during pregnancy.
- Dosage adjustment may be required if patient is taking concomitantly either an H2-receptor antagonist or tenofovir DF during the second or third trimester.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LABOR & DELIVERY**

- Drug can cause increased risk of adverse reactions in mother during the first 2 months after delivery because drug exposure could be higher during this time.
- Neonate may develop severe hyperbilirubinemia during the first few days following birth if exposed to drug in utero.

### **LACTATION**

- Drug is present in breast milk
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection as well as the possibility of potential drug-induced adverse reactions in the infant.

## **Nursing Considerations**

- Be aware that atazanavir is not recommended for HIV treatment-experienced patients with end-stage renal disease managed with hemodialysis. Expect all patients to have renal laboratory testing prior to

atazanavir being initiated and periodically throughout drug therapy. Testing should include estimated creatinine clearance, serum creatinine, and urinalysis with microscopic examination. If kidney disease occurs and becomes progressive, expect that atazanavir may be discontinued.

- Expect patients with underlying hepatitis B or C viral infections or marked elevations in transaminases that have occurred before atazanavir treatment to have hepatic function evaluated prior to start of therapy and periodically during treatment, because these patients may experience further transaminase elevations or hepatic decompensation while taking atazanavir.
- Be aware that patients with preexisting conduction system disease should be monitored by ECG.
- Administer atazanavir with food.
- Mix oral powder as follows: Determine number of packets needed and tap each packet to settle powder. Using a clean pair of scissors, cut each packet along the dotted line. Mix with food such as applesauce or yogurt using a minimum of 1 tablespoon of food mixed in a container and then administered to patient. Follow with mixing second tablespoon in container and administering the residual mixture. For infants, oral powder may be mixed with 30 ml of infant formula, milk, or water if infant can drink from a cup. After administering drug in this way, add 15 ml of liquid to the cup and have child drink the residual mixture. Know that if water was used to mix the drug, the child should immediately be given something to eat. For infants less than 6 months old who cannot drink from a cup or eat solid food, mix with 10 ml of infant formula and give using an oral dosing syringe and administer into either inner cheek of infant. Add an additional 10 ml of formula to cup used to mix drug and formula, draw up residual mixture, and administer to infant. Do not use an infant bottle to administer drug, because full dose may not be delivered. Know that when drug is mixed with food or liquid, it must be administered within 1 hr of preparation. Mixture may remain at room temperature during this time.
- Administer ritonavir, if prescribed, immediately after atazanavir.
- Monitor patient closely for the appearance of a rash. Although common and usually not affecting the use of atazanavir, some rashes may become severe and life-threatening. Report all rashes to prescriber and expect drug to be discontinued if rash becomes severe.
- Report signs or symptoms suggestive of cholelithiasis or nephrolithiasis to prescriber, as drug may have to be temporarily interrupted or discontinued if confirmed.
- Monitor patient's blood glucose level throughout atazanavir therapy, because drug has been associated with new-onset diabetes mellitus and

exacerbation of preexisting diabetes mellitus. Treat hyperglycemia as prescribed.

- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including atazanavir. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus infection, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.
- Monitor patients with hemophilia for increased bleeding, because spontaneous skin hemarthrosis and hematomas have occurred in these patients while taking atazanavir. Provide supportive care as prescribed.

## PATIENT TEACHING

- Instruct patient prescribed capsule form of atazanavir not to open capsule and to ingest it whole.
- Instruct patient, parent, or caregiver how to mix oral powder form, if prescribed. Tell parent/caregiver of an infant younger than 6 months who cannot drink from a cup or eat solid food to mix with infant formula but to administer it with an oral dosing syringe. The drug should not be delivered using an infant bottle.
- Tell patient prescribed both atazanavir and ritonavir to take atazanavir first and then immediately take ritonavir.
- Alert patient that atazanavir may redistribute or cause accumulation of body fat which may include breast enlargement, a buffalo hump on the back of the neck, central obesity, and wasting appearance of extremities and face.
- Advise patient to report the appearance of a rash to prescriber. Inform patient that severe skin reactions may occur that begin with a rash and caution patient to report any rash immediately to prescriber.
- Advise patient to report dizziness or lightheadedness to prescriber because drug may causes changes in how the heart functions. Also tell patient to report any yellowing of the skin or whites of the eyes.
- Stress importance of maintaining adequate hydration throughout therapy as drug may cause chronic kidney disease.
- Alert patient, parent, or caregiver using the oral powder form of atazanavir that it contains 35 mg of phenylalanine, which can be harmful

if patient has phenylketonuria. The capsule form of drug contains no phenylalanine.

- Review signs and symptoms of the presence of gallbladder or kidney stones with patient and advise patient to notify prescriber if any such signs and symptoms develop, as drug may have to be temporarily withheld or discontinued.
- Stress importance of informing all prescribers of atazanavir therapy, because drug interacts with many other drugs. Tell patient not to take any over-the-counter medication, including herbals, without consulting prescriber first.
- Tell patient with diabetes mellitus to monitor glucose levels during atazanavir therapy, as adjustments in her diabetes treatment regimen may be needed. Also review signs and symptoms of diabetes mellitus with all patients, because new-onset diabetes mellitus has occurred during atazanavir therapy.
- Instruct patient to report any signs and symptoms of infection or persistent or unusual adverse effects to prescriber.
- Encourage women who become pregnant to register on the pregnancy exposure registry through their prescriber.
- Instruct women not to breastfeed while taking atazanavir as drug may pass through breast milk to the infant.

## atenolol

### Tenormin

## Class and Category

*Pharmacologic class:* Beta-adrenergic blocker (beta<sub>1</sub> and at high doses beta<sub>2</sub>)

*Therapeutic class:* Antianginal, antihypertensive

## Indications and Dosages

- *To treat angina pectoris; to treat hypertension*

## **TABLETS**

**Adults.** 50 mg daily increased, as needed, after 1 to 2 wk to 100 mg daily. *Maximum:* 100 mg for treatment of hypertension; 200 mg for treatment of angina pectoris.

- *To treat acute myocardial infarction in hemodynamically stable patients*

## **I.V. INJECTION**

**Adults.** 5 mg given over 5 min followed in 10 min by 5 mg given over 5 min.

## **TABLETS**

**Adults.** *Initial:* 50 mg following last I.V. dose, then 50 mg 12 hr later. *Maintenance:* 100 mg once daily or 50 mg twice daily for 6 to 9 days or until discharge.

***DOSAGE ADJUSTMENT*** Dosage usually not increased above 50 mg daily P.O. for the elderly and for patients with a creatinine clearance, of 15 to 35 ml/min. For patients with creatinine clearance less than 15 ml/min, dosage reduced to 25 mg daily.

Route	Onset	Peak	Duration
P.O.	1 hr	2-4 hr	24 hr

## **Mechanism of Action**

Inhibits stimulation of beta<sub>1</sub>-receptor sites, located mainly in the heart, decreasing cardiac excitability, cardiac output, and myocardial oxygen demand. Atenolol also acts to decrease release of renin from the kidneys, aiding in reducing blood pressure. At high doses, it inhibits

stimulation of beta<sub>2</sub> receptors in the lungs, which may cause bronchoconstriction.

## Contraindications

Anesthesia with agents that produce myocardial depression, cardiogenic shock, heart block greater than first degree, hypersensitivity to atenolol, other beta blockers or their components, overt heart or uncontrolled failure, hypotension, metabolic acidosis, pheochromocytoma in the absence of alpha-blockade, right ventricular failure secondary to pulmonary hypertension, severe peripheral arterial disorders, sick sinus syndrome, sinus bradycardia

## Interactions

### DRUGS

*amiodarone and class I antiarrhythmics such as disopyramide:* Additive atenolol effects with increased risk of asystole, heart failure, and severe bradycardia

*anaesthetic agents:* Possibly induced hypotensive state with associated reflex tachycardia.

*calcium channel blockers, such as verapamil and diltiazem:* Possibly symptomatic bradycardia and conduction abnormalities

*catecholamine-depleting drugs, such as guanethidine, reserpine:* Additive antihypertensive effect

*clonidine:* Possible rebound hypertension following discontinuation of clonidine

*digoxin, flunitrazepam:* Possible potentiate bradycardia

*dihydropyridines such as nifedipine:* Increased risk of cardiac failure and hypotension in patients with latent cardiac insufficiency

*NSAIDs*: Possible blunting of the antihypertensive effect of atenolol

## Adverse Reactions

**CNS**: Depression, disorientation, dizziness, drowsiness, emotional lability, fatigue, fever, lethargy, light-headedness, short-term memory loss, vertigo

**CV**: **Arrhythmias, including bradycardia and heart block; cardiogenic shock**; cold arms and legs; **mitral insufficiency; myocardial reinfarction**; orthostatic hypotension; Raynaud's phenomenon

**EENT**: Dry eyes, **laryngospasm**, pharyngitis

**GI**: Diarrhea, **ischemic colitis, mesenteric artery thrombosis**, nausea

**GU**: **Renal failure**

**HEME**: **Agranulocytosis**

**MS**: Leg pain

**RESP**: **Bronchospasm**, dyspnea, **pulmonary emboli, respiratory distress**, wheezing

**SKIN**: Erythematous rash

**Other**: **Allergic reaction**

## Childbearing Considerations

### PREGNANCY

- Drug crosses placental barrier and can cause fetal harm.
- Use of drug starting in the second trimester has caused a lower birth rate for gestational age of fetus; in the third trimester bradycardia may occur in the fetus.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LABOR & DELIVERY**

- Newborns are at risk for bradycardia and hypoglycemia if exposed to drug in utero.

## **LACTATION**

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential adverse reactions in the breastfed infant such as bradycardia and hypoglycemia.

## **Nursing Considerations**

- Use atenolol cautiously in patients with heart failure controlled by digitalis glycosides or diuretics, patients with conduction abnormalities or left ventricular dysfunction who take verapamil or diltiazem, patients with arterial circulatory disorders, and patients with impaired renal function.
- Use atenolol cautiously in diabetic patients because it may mask tachycardia caused by hypoglycemia. Unlike other beta-adrenergic blockers, it doesn't mask other signs of hypoglycemia, cause hypoglycemia, or delay the return of blood glucose to a normal level.
- Monitor patient for heart failure. At first sign of heart failure, expect patient to receive a digitalis glycoside, a diuretic, or both and to be monitored closely. If failure continues, expect to stop atenolol.
- Closely monitor patient with hyperthyroidism because atenolol may mask some signs of thyrotoxicosis. Abrupt withdrawal of atenolol may precipitate thyrotoxicosis.
- Know that if patient also receives clonidine, expect to stop atenolol several days before gradually withdrawing clonidine. Then expect to restart atenolol therapy several days after clonidine has been discontinued.
- Stop atenolol and notify prescriber if patient develops bradycardia, hypotension, or other serious adverse reaction.

- Be aware that chronic beta blocker therapy such as atenolol is not routinely withheld prior to major surgery because the benefits outweigh the risks associated with its use with general anesthesia and surgical procedures.

## PATIENT TEACHING

- Instruct patient not to stop taking atenolol abruptly. Otherwise, angina may worsen, and an MI or arrhythmia may occur.
- Tell him to perform minimal physical activity to prevent chest pain when he is being weaned from atenolol therapy.
- Instruct patient to take a missed dose as soon as possible. However, if it's within 8 hours of the next scheduled dose, tell him to skip the missed dose and return to his regular schedule.
- Explain that atenolol may alter serum glucose level and mask hypoglycemia.
- Inform the patient that he may experience fatigue and reduced tolerance to exercise and that he should notify his prescriber if this interferes with his normal lifestyle.

## atomoxetine hydrochloride

### Strattera

## Class and Category

*Pharmacologic class:* Selective norepinephrine reuptake inhibitor

*Therapeutic class:* Anti-ADHD agent

## Indications and Dosages

- *To treat attention deficit hyperactivity disorder (ADHD)*

## **CAPSULES**

**Adults and children weighing more than 70 kg (154 lb).** *Initial:* 40 mg daily, increased after at least 3 days to 80 mg daily given either as a single dose in the morning or in evenly divided doses morning and late afternoon or early evening. After 2 to 4 additional wk, dosage may be increased to 100 mg daily if optimal response hasn't been achieved. *Maximum:* 100 mg daily.

**Adults and children weighing 70 kg (154 lb) or less.** *Initial:* 0.5 mg/kg daily, increased after at least 3 days to 1.2 mg/kg daily given either as a single dose in the morning or in evenly divided doses morning and late afternoon or early evening, as needed. *Maximum:* 1.4 mg/kg or 100 mg daily, whichever is less.

***DOSAGE ADJUSTMENT*** For patients with moderate (Child-Pugh Class B) hepatic impairment, dosage reduced by 50%. For patients with severe (Child-Pugh Class C) hepatic impairment, dosage reduced by 75%. For patients weighing more than 70 kg and taking strong CYP2D6 inhibitors (fluoxetine, paroxetine, or quinidine), initial dosage of 40 mg daily increased to 80 mg daily only if symptoms fail to improve after 4 wk. For patients weighing 70 kg or less and taking strong CYP2D6 inhibitors, initial dosage of 0.5 mg/kg daily increased to 1.2 mg/kg daily only if symptoms fail to improve after 4 wk.

## **Mechanism of Action**

Selectively inhibits presynaptic norepinephrine transport in the nervous system to increase attention span and produce a calming effect.

# Contraindications

Angle-closure glaucoma, hypersensitivity to atomoxetine or its components, pheochromocytoma, severe cardiovascular disorders, use within 14 days of MAO inhibitor therapy

# Interactions

## DRUGS

*albuterol and other beta<sub>2</sub> agonists*: May potentiate action of albuterol and other beta<sub>2</sub> agonists on cardiovascular system

*antihypertensives, pressor agents*: Possibly increased blood pressure

*CYP2D6 inhibitors (such as fluoxetine, paroxetine, and quinidine)*: Increased blood atomoxetine level

*MAO inhibitors*: Possibly induced hypertensive crisis

# Adverse Reactions

**CNS**: Aggressiveness, anxiety, chills, crying, **CVA**, depression, dizziness, early morning awakening, fatigue, headache, hostility, hypoaesthesia, insomnia, irritability, jittery feeling, lethargy, mood changes, paresthesia (children and adolescents), peripheral coldness, pyrexia, rigors, sedation, **seizures**, sensory disturbances, sleep disturbance, somnolence, **suicidal ideation**, syncope, tics, tremor, unusual dreams

**CV**: Chest pain, hypertension, orthostatic hypotension, **MI**, palpitations, **QT-interval prolongation**, Raynaud's phenomenon, tachycardia

**EENT**: Blurred vision, conjunctivitis, dry mouth, ear infection, mydriasis, nasal congestion, nasopharyngitis,

pharyngitis, rhinorrhea, sinus congestion

**ENDO:** Hot flashes

**GI:** Abdominal pain (upper), anorexia, constipation, diarrhea, dyspepsia, elevated liver enzymes, flatulence, gastroenteritis (viral), indigestion, nausea, **severe hepatic dysfunction**, vomiting

**GU:** Decreased libido, dysmenorrhea, dysuria, ejaculation disorders, erectile dysfunction, impotence, male pelvic pain, menstrual irregularities, orgasm abnormality, priapism, prostatitis, urinary hesitancy (children and adolescents), urine retention (children and adolescents)

**MS:** Arthralgia, back pain, myalgia, **rhabdomyolysis**

**RESP:** Cough, upper respiratory tract infection

**SKIN:** Alopecia, dermatitis, diaphoresis, hyperhidrosis, pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, flu-like symptoms, weight loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug is not recommended during pregnancy unless benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## REPRODUCTION

- Women of childbearing age should avoid pregnancy during drug therapy by using an effective contraceptive.

## Nursing Considerations

- Use atomoxetine cautiously in patients with cerebrovascular or CV disease (especially hypertension or tachycardia) because drug may increase blood pressure and heart rate. Also use cautiously in those prone to orthostatic hypotension and those with serious structural cardiac abnormalities, cardiomyopathy, serious heart rhythm abnormalities, or other serious cardiac problems because drug may increase risk of sudden death from these conditions.

**WARNING** Monitor patient closely for evidence of suicidal thinking and behavior as well as for psychotic or manic symptoms such as hallucinations, delusional thinking, or mania because atomoxetine increases the risk of suicidal ideation and the onset of psychotic or manic symptoms. In addition, monitor patients, especially children and adolescents with ADHD, for the appearance or worsening of aggressive behavior or hostility. Notify prescriber if psychiatric adverse reactions are observed during atomoxetine therapy.

- Obtain baseline blood pressure and heart rate before starting therapy. Monitor patient's vital signs after dosage increases and periodically during therapy.
- Monitor patient closely for allergic reactions. If these occur, notify prescriber.
- Monitor child's or adolescent's growth and weight. Expect to interrupt therapy, as prescribed, if patient isn't growing or gaining weight appropriately.
- Monitor patient's liver function studies, as ordered. Notify prescriber immediately if enzyme levels are elevated or patient has evidence of hepatic dysfunction. Expect to stop drug permanently.

## PATIENT TEACHING

- Caution patient not to open capsules. If a capsule opens, urge patient to promptly wash his hands and any surface drug touches. If drug gets in his eyes, tell him to flush immediately with water and seek medical care.
- Instruct patient or parent to immediately report to prescriber any adverse reactions to atomoxetine therapy, such as facial swelling, itching, or rash.

**WARNING** Urge parents to watch their child or adolescent closely for evidence of abnormal thinking or behavior, or increased aggression or hostility. Emphasize need to notify prescriber about unusual changes.

- Urge patient to tell prescriber immediately about dark urine, flu-like symptoms, itchiness, right upper abdominal pain, or yellowing of his skin or eyes. Also tell patient to notify prescriber immediately if he experiences exertional chest pain, unexplained syncope, or other symptoms suggestive of heart disease.
- Caution patient to assume sitting or standing position slowly because of drug's potential effect on blood pressure.
- Urge male patient to seek immediate medical attention for a penile erection that becomes prolonged or painful.
- Advise patient to report urinary hesitancy or urine retention to prescriber.
- Remind patient of the importance of alerting all prescribers to any OTC drugs, dietary supplements, or herbal remedies he's taking.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Reassure patient or parent that drug doesn't cause physical or psychological dependence.
- Instruct patient or parent to monitor weight during therapy.

**atorvastatin calcium**

# Lipitor

## Class and Category

*Pharmacologic class:* HMG-CoA reductase inhibitor

*Therapeutic class:* Antihyperlipidemic

## Indications and Dosages

- *To control lipid levels as adjunct to diet in primary (heterozygous familial and nonfamilial) hypercholesterolemia and mixed dyslipidemia*

### **TABLETS**

**Adults.** *Initial:* 10 or 20 mg once daily; then increased according to lipid level. *Maintenance:* 10 to 80 mg once daily.

***DOSAGE ADJUSTMENT*** Initial dose may be increased to 40 mg once daily for patients who need cholesterol level reduced more than 45%.

- *To control lipid levels in homozygous familial hypercholesterolemia*

### **TABLETS**

**Adults.** 10 to 80 mg daily.

- *To control lipid levels in pediatric heterozygous familial hypercholesterolemia*

### **TABLETS**

**Adolescents and children ages 10 to 17.**

*Initial:* 10 mg daily, adjusted at intervals of 4 wk or more, as needed. *Maximum:* 20 mg daily.

- *To reduce risk of acute cardiovascular events such as angina, CVA, or MI and to reduce risk for revascularization procedures or hospitalization for congestive heart failure in patients with coronary heart disease*

## **TABLETS**

**Adults.** 10 to 80 mg once daily.

### ***DOSAGE ADJUSTMENT FOR ALL INDICATIONS***

For patient taking azole antifungals, colchicine, erythromycin, fibric acid derivatives, lipid-modifying doses of niacin, lopinavir plus ritonavir, simeprevir, lowest dosage should be used. For patient taking clarithromycin, darunavir plus ritonavir, elbasvir plus grazoprevir, fosamprenavir, fosamprenavir plus ritonavir, itraconazole, or saquinavir plus ritonavir, dosage should not exceed 20 mg daily. For patient taking nelfinavir, dosage should not exceed 40 mg daily.

## **Mechanism of Action**

Reduces plasma cholesterol and lipoprotein levels by inhibiting HMG-CoA reductase and cholesterol synthesis in the liver and by increasing the number of LDL receptors on liver cells to enhance LDL uptake and breakdown.

## **Contraindications**

Active hepatic disease, breastfeeding, hypersensitivity to atorvastatin or its components, pregnancy, unexplained persistent rise in serum transaminase level

# Interactions

## DRUGS

*azole antifungals, colchicine, erythromycin, gemfibrozil, lipid-modifying doses of niacin, other fibrates:* Increased risk of myopathy and rhabdomyolysis

*cyclosporine, CYP3A4 strong inhibitors such as clarithromycin, HIV and HCV protease inhibitors including combination drugs, itraconazole letermovir:* Possibly increased plasma concentrations of atorvastatin and adverse reactions such as myopathy and rhabdomyolysis  
*digoxin:* Increased digoxin level and increased risk of toxicity

*efavirenz, rifampin, other CYP450 3A4 inducers:* Possible decreased plasma atorvastatin level and effectiveness  
*oral contraceptives such as ethinyl estradiol and norethindrone:* Increased hormone levels

## FOODS

*grapefruit juice:* Increased blood atorvastatin level

## Adverse Reactions

**CNS:** Abnormal dreams, amnesia, asthenia, cognitive impairment, depression, dizziness, emotional lability, facial paralysis, fatigue, fever, headache, hyperkinesia, lack of coordination, malaise, paresthesia, peripheral neuropathy, somnolence, syncope, weakness

**CV:** **Arrhythmias**, elevated serum CK level, orthostatic hypotension, palpitations, phlebitis, vasodilation

**EENT:** Amblyopia, altered refraction, dry eyes, dry mouth, epistaxis, eye hemorrhage, gingival hemorrhage, glaucoma,

glossitis, hearing loss, lip swelling, loss of taste, pharyngitis, sinusitis, stomatitis, taste perversion, tinnitus

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Abdominal or biliary pain, anorexia, colitis, constipation, diarrhea, duodenal or stomach ulcers, dysphagia, elevated liver enzymes, eructation, esophagitis, flatulence, gastroenteritis, **hepatic failure, hepatitis, pancreatitis, rectal hemorrhage**, vomiting

**GU:** Abnormal ejaculation; cystitis; decreased libido; dysuria; epididymitis; hematuria; impotence; nephritis; nocturia; renal calculi; urinary frequency, incontinence, or urgency; urine retention; vaginal hemorrhage

**HEME:** Anemia, **thrombocytopenia**

**MS:** Arthralgia, back or muscle pain, bursitis, gout, **immune-mediated necrotizing myopathy**, leg cramps, myalgia, myasthenia gravis, myopathy, myositis, neck rigidity, **rhabdomyolysis**, tendon contracture or rupture, tenosynovitis, torticollis

**RESP:** Dyspnea, pneumonia

**SKIN:** Acne, alopecia, contact dermatitis, diaphoresis, dry skin, ecchymosis, eczema, **erythema multiforme**, petechiae, photosensitivity, pruritus, rash, seborrhea, **Stevens-Johnson, toxic epidermal necrolysis**, ulceration, urticaria

**Other:** **Anaphylaxis, angioedema**, flu-like symptoms, infection, lymphadenopathy, weight gain

## **Childbearing Considerations**

### **PREGNANCY**

- Drug may cause fetal harm.
- Drug is contraindicated during pregnancy.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Drug is contraindicated during breastfeeding because of potential for serious adverse reactions in breastfed infant.

## **REPRODUCTION**

- Women of childbearing age should use effective contraception during drug therapy.

## **Nursing Considerations**

- Know that atorvastatin is used in patients with homozygous familial hypercholesterolemia as an adjunct to other lipid-lowering treatments or alone only if other treatments aren't available.
- Know that treatment of heterozygous familial hypercholesterolemia, in children who have failed an adequate trial of diet therapy, may include atorvastatin therapy if their LDL-C is 190 mg/dl or greater, or their LDL-C is 160 mg/dl or greater and they have a positive family history of familial hypercholesterolemia or premature cardiovascular disease in a first- or second-degree relative, or two or more other cardiovascular risk factors are present.
- Be aware that atorvastatin may be used with colestipol or cholestyramine for additive antihyperlipidemic effects.
- Know that atorvastatin should not be used in patients taking cyclosporine, gemfibrozil, tipranavir plus ritonavir, or telaprevir because of high risk for rhabdomyolysis with acute renal failure.
- Use atorvastatin cautiously in patients who consume substantial quantities of alcohol or have a history of liver disease because atorvastatin use increases risk of liver dysfunction.
- Expect atorvastatin to be used in patients without obvious coronary artery disease (CAD) but with multiple risk factors (such as age 55 or over,

family history of early CAD, history of hypertension or low HDL level, or smoker).

- Expect liver function tests to be performed before atorvastatin therapy starts and then thereafter as clinically necessary. If clinical symptoms such as hyperbilirubinemia and jaundice occurs, notify prescriber and expect atorvastatin therapy to be discontinued until cause of liver dysfunction has been identified. If no cause can be found, expect the drug to be discontinued permanently.
- Expect to measure lipid levels 2 to 4 weeks after therapy starts, to adjust dosage as directed, and to repeat periodically until lipid levels are within desired range.
- Monitor diabetic patient's blood glucose levels because atorvastatin therapy can affect blood glucose control.

**WARNING** Notify prescriber immediately and expect to withhold atorvastatin therapy if patient develops an acute condition suggestive of a myopathy (unexplained muscle pain, tenderness or weakness, especially if accompanied by elevated CPK level, fever, or malaise) or has a risk factor predisposing to the development of renal failure secondary to rhabdomyolysis, such as an acute severe infection; hypotension; major surgery; severe electrolyte, endocrine, or metabolic disorder; or uncontrolled seizures.

## **PATIENT TEACHING**

- Emphasize that atorvastatin is an adjunct to—not a substitute for—a low-cholesterol diet.
- Tell patient to take drug at the same time each day to maintain its effects.
- Instruct patient to take a missed dose as soon as possible. If it's almost time for his next dose, he should skip the missed dose. Tell him not to double the dose.
- Instruct patient to consult prescriber before taking OTC niacin because of increased risk of rhabdomyolysis.
- Advise patient to notify prescriber immediately if he develops unexplained muscle pain, tenderness, or weakness, especially if accompanied by

fatigue or fever.

- Reinforce the benefits of therapy, and urge patient to comply if possible.
- Advise patient with diabetes to monitor blood glucose levels closely.
- Inform women of childbearing age to use effective contraception while taking atorvastatin because atorvastatin is contraindicated in pregnancy. Tell female patient to notify prescriber immediately if pregnancy is suspected or known, as drug will have to be discontinued. Also tell mothers that breastfeeding is contraindicated during atorvastatin therapy.

## atovaquone

### Mepron

## Class and Category

*Pharmacologic class:* Ubiquinone analogue

*Therapeutic class:* Antiprotozoal

## Indications and Dosages

- *To prevent Pneumocystis jiroveci pneumonia in patients who can't tolerate trimethoprim-sulfamethoxazole*

### SUSPENSION, TABLETS

**Adults and adolescents.** 1,500 mg (10 ml) once daily with meals.

- *To treat mild to moderate P. jiroveci pneumonia in patients who can't tolerate trimethoprim-sulfamethoxazole*

## SUSPENSION, TABLETS

**Adults and adolescents.** 750 mg (5 ml) twice daily with meals for 21 days. *Maximum:* 1,500 mg/day.

## Mechanism of Action

May destroy *P. jiroveci* organisms by inhibiting the enzymes needed to synthesize nucleic acid and adenosine triphosphate.

## Contraindications

Hypersensitivity to atovaquone or its components

## Interactions

### DRUGS

*indinavir:* Possible loss of efficacy of indinavir  
*metoclopramide, rifabutin, rifampin, tetracycline:* Possibly decreased blood atovaquone level

## Adverse Reactions

**CNS:** Fever, headache, insomnia

**EENT:** Rhinitis, throat tightness, vortex keratopathy

**GI:** Abdominal pain, diarrhea, elevated liver enzymes, **hepatic failure, hepatitis**, nausea, **pancreatitis**, vomiting

**GU:** **Acute renal dysfunction**

**HEME:** Anemia, **thrombocytopenia**

**RESP:** **Bronchospasm**, cough, dyspnea

**SKIN:** Desquamation, **erythema multiforme**, **Stevens-Johnson syndrome**, rash, urticaria

**Other:** **Allergic reaction**, **angioedema**, **methemoglobinemia**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Centers for Disease Control and Prevention recommend women infected with HIV-1 not breastfeed their infant to avoid risking postnatal transmission of HIV-1.

## Nursing Considerations

- Use atovaquone cautiously in patient with severe hepatic impairment because, although rare, serious adverse reactions affecting liver function may occur.
- Monitor blood test results because atovaquone may decrease serum sodium, hemoglobin levels, and neutrophil count; and may increase AST, ALT, alkaline phosphatase, and serum amylase levels.
- Crush atovaquone tablets, if needed.
- Don't use tablets and oral suspension interchangeably; they aren't bioequivalent.

### PATIENT TEACHING

- Instruct patient to take atovaquone with meals for maximum effectiveness.
- Remind patient taking suspension form to shake the suspension gently before using each time.
- Instruct patient to take a missed dose as soon as possible. If it's almost time for the next dose, tell him to skip the missed dose. Tell him not to double the next dose.
- Tell patient to notify prescriber if his condition doesn't improve in a few days or if he develops signs of an allergic reaction, such as fever or rash.

**atropine**

**AtroPen**

**atropine sulfate**

## Class and Category

*Pharmacologic class:* Anticholinergic

*Therapeutic class:* Antiarrhythmic, antimuscarinic

## Indications and Dosages

- *To reduce secretions and block vagal effects preoperatively*

### **I.V., I.M., OR SUBCUTANEOUS INJECTION**

**Adults.** 0.5 to 1 mg given 30 to 60 min before surgery, repeated in 1 to 2 hr, if needed.

**Children.** 0.01 to 0.03 mg/kg given 30 to 60 min before surgery, repeated in 4 to 6 hr, as needed.

- *To reverse adverse muscarinic anticholinesterase effects*

### **I.V. INJECTION (ATROPINE SULFATE)**

**Adults.** 0.6 to 1.2 mg for each 0.5 to 2.5 mg of neostigmine methylsulfate or 10 to 20 mg of pyridostigmine bromide.

- *As an antidote for organophosphorus or muscarinic mushroom poisoning*

### **I.M. INJECTION, I.V. INJECTION, SUBCUTENOUS INJECTION (ATROPINE SULFATE)**

**Adults.** 2 to 3 mg, repeated every 20 to 30 min, as needed, until signs of poisoning are significantly lessened or signs of atropine toxicity occur.

### **ENDOTRACHEAL INSTILLATION (ATROPINE SULFATE)**

**Adults.** 1 to 2 mg diluted in no more than 10 ml of sterile water or normal saline.

- *To treat bradycardic cardiac arrest*

### **I.V. INJECTION (ATROPINE SULFATE)**

**Adults.** 1 mg, repeated in 3 to 5 min, and repeated again in 3 to 5 min, as needed. *Maximum:* 3 mg total dose.

### **ENDOTRACHEAL INSTILLATION (ATROPINE SULFATE)**

**Adults.** 1 to 2 mg diluted in no more than 10 ml of sterile water or normal saline.

- *To treat known or suspected exposure to chemical nerve agent or insecticide*

## I.M. INJECTION (ATROPEN)

**Adults and children weighing over 41 kg (90 lb) with two or more mild symptoms.** 2 mg, if severe symptoms develop after injection, two or more 2-mg injections given in rapid succession 10 min after initial injection.

**Adults and children weighing over 41 kg (90 lb) who are unconscious or have other severe symptoms.** 2 mg given immediately 3 times in rapid succession.

**Children weighing 18 to 41 kg (40 to 90 lb) with two or more mild symptoms.** 1 mg, if severe symptoms develop after injection, two more 1-mg injections given in rapid succession 10 min after initial injection.

**Children weighing 18 to 41 kg (40 to 90 lb) who are unconscious or exhibit any other severe symptoms.** 1 mg given immediately 3 times in rapid succession.

**Children weighing 7 to 18 kg (15 to 40 lb) with two or more mild symptoms.** 0.5 mg. If severe symptoms develop after injection, two more 0.5-mg injections given in rapid succession 10 min after initial injection.

**Children weighing 7 to 18 kg (15 to 40 lb) who are unconscious or exhibit any other severe symptoms.** 0.5 mg given immediately three times in rapid succession.

Route	Onset	Peak	Duration
I.V.	Immediate	2-4 min	Brief
I.M.	5-40 min	20-60 min	Brief
SubQ	Unknown	Unknown	Brief

## Mechanism of Action

Inhibits acetylcholine's muscarinic action at the neuroeffector junctions of smooth muscles, cardiac muscles, exocrine glands, SA and AV nodes, and the

urinary bladder. In small doses, atropine inhibits salivary and bronchial secretions and diaphoresis. In moderate doses, it increases impulse conduction through the AV node and increases heart rate. In large doses, it decreases GI and urinary tract motility and gastric acid secretion.

## Contraindications

Hypersensitivity to atropine or other belladonna alkaloids or their components

## Interactions

### DRUGS

*amantadine, anticholinergics, antidyskinetics, glutethimide, meperidine, muscle relaxants, phenothiazines, tricyclic antidepressants and other drugs with anticholinergic properties, including antiarrhythmics (disopyramide, procainamide, quinidine), antihistamines, buclizine:*

Increased atropine effects

*ketoconazole:* Decreased ketoconazole absorption

*levodopa:* Decreased plasma levodopa concentration and effectiveness

*opioid analgesics:* Increased risk of ileus, severe constipation, and urine retention

*potassium chloride, especially wax-matrix forms:* Possibly GI ulcers

*urinary alkalizers (calcium or magnesium antacids, carbonic anhydrase inhibitors, citrates, sodium bicarbonate):* Delayed excretion, increased risk of adverse atropine effects

## Adverse Reactions

**CNS:** Agitation, amnesia, anxiety, ataxia, Babinski's or Chaddock's reflex, behavioral changes, CNS stimulation (at high doses), **coma**, confusion, decreased concentration, decreased tendon reflexes, delirium, dizziness, drowsiness, EEG abnormalities, excessive thirst, fatigue, fever, hallucinations, headache, **hyperpyrexia**, hyperreflexia, insomnia, lethargy, mania, mental disorders, nervousness, paranoia, restlessness, **seizures**, sensation of intoxication, somnolence, stupor, syncope, vertigo, weakness

**CV:** **Arrhythmias**, **bradycardia (at low doses)**, **cardiac dilation**, chest pain, hypertension, **hypotension**, **left ventricular failure**, **MI**, palpitations, tachycardia (at high doses), **weak or impalpable peripheral pulses**

**EENT:** Acute angle-closure glaucoma, altered taste, blepharitis, blindness, blurred vision, conjunctivitis, cyclophoria, cycloplegia, decreased visual acuity or accommodation, dry eyes or conjunctiva, dry mucous membranes, dry mouth, eye irritation, eyelid crusting, heterophoria, increased intraocular pressure, keratoconjunctivitis, lacrimation, laryngitis, **laryngospasm**, mydriasis, nasal congestion, oral lesions, photophobia, pupils poorly reactive to light, strabismus, tongue chewing

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Abdominal distention, abdominal pain, bloating, constipation, decreased bowel sounds or food absorption, delayed gastric emptying, dysphagia, heartburn, ileus, nausea, vomiting

**GU:** Bladder distention, difficulty urinating, elevated BUN, enuresis, impotence, loss of libido, polydipsia, urinary hesitancy, urinary urgency, urine retention

**HEME:** Anemia, elevated erythrocytes and hemoglobin, leukocytosis

**MS:** Dysarthria, hypertonia, muscle twitching

**RESP:** Bradypnea, exacerbation of chronic lung disease, dyspnea, inspiratory stridor, pulmonary edema, respiratory failure, shallow breathing, subcostal recession, tachypnea

**SKIN:** Cold skin, decreased or excessive sweating, dermatitis, exfoliative dermatitis, flushing, rash, urticaria

**Other:** Anaphylaxis, dehydration, hypokalemia, hyponatremia, injection-site pain, sensations of warmth

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm although it does cross the placental barrier.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Know that for patient prescribed AtroPen for suspected nerve gas or insecticide exposure, dosage is determined by severity of symptoms. Mild symptoms include acute onset of stomach cramps, blurred vision,

bradycardia, chest tightness, difficulty breathing, excessive unexplained teary eyes or runny nose, increased salivation, miosis, muscle twitching, nausea, tachycardia, unexplained wheezing or coughing, and vomiting. Severe symptoms include confusion or other strange behavior, extreme secretions from airway or lungs, involuntary urination and defecation, seizures, severe difficulty breathing, severe muscle twitching and general weakness, tremors, and unconsciousness.

**WARNING** Monitor patient closely for hypersensitivity reactions, including anaphylaxis, after drug is given.

- Be aware that high-dose atropine sulfate should not be used in patients with ulcerative colitis because of risk of toxic megacolon or in patients with hiatal hernia and reflux esophagitis because of risk of esophagitis.
- Know that AtroPen has no absolute contraindications when used to treat life-threatening nerve gas or insecticide exposure. However, the 2 mg atropine autoinjector should not be used in children weighing 41 kg (90 lb) or less for any indication as its safety and effectiveness has not been established.
- Caution should be used when atropine is given to patients with known cardiac conduction problems or cardiovascular disease because of its effect on the heart. Caution should also be used when atropine is given to patients with acute glaucoma, partial pyloric stenosis, or significant bladder outflow obstruction.
- Monitor patients with chronic lung disease because atropine may cause thickening of bronchial secretions and formation of dangerous viscid plugs.

**WARNING** Assess for symptoms of toxic doses of atropine, such as agitation, confusion, drowsiness, and excitement, which are likely to affect elderly patients even with low doses. If symptoms occur, take safety precautions to prevent injury.

- Monitor elderly patients receiving atropine closely because they are more susceptible to the effects of the drug.

- Assess bowel and bladder elimination. Notify prescriber of constipation, diarrhea, urinary hesitancy, or urine retention.

## PATIENT TEACHING

- Teach patient prescribed an AtroPen because of risk of nerve gas or insecticide exposure, when and how to self-administer the drug. Remind patient that if the AtroPen is used, this is only an initial emergency treatment and they still need to seek additional emergency care.
- Advise patient to notify prescriber if he has constipation, difficulty urinating, or persistent or severe diarrhea.
- Inform patient that atropine may inhibit sweating. Advise patient to avoid excessive exercise or heat exposure, which can lead to heat injury.

**auranofin**

**Ridaura**

## Class and Category

*Pharmacologic class:* Gold salt

*Therapeutic class:* Anti-inflammatory (antiarthritic)

## Indications and Dosages

- *To treat active rheumatoid arthritis in patients that are intolerant to or unresponsive to nonsteroidal anti-inflammatory drugs (NSAIDs)*

## CAPSULES

**Adults.** *Initial:* 6 mg daily or 3 mg twice daily, increased after 6 mo to 9 mg (in 3 divided doses) daily, if needed and

tolerated.

Route	Onset	Peak	Duration
P.O.	3-6 mo	1-2 hr	Up to 26 days

## Mechanism of Action

Decreases rheumatoid factor and humoral antibody (immunoglobulin) levels. Although exact anti-inflammatory action is unknown, drug may suppress the increased phagocytic activity of macrophages and polymorphonuclear leukocytes that occur with rheumatoid arthritis and thereby inhibit release of destructive enzymes that cause joint inflammation.

## Contraindications

Gold-induced disorders such as anaphylactic reactions, bone marrow aplasia, exfoliative dermatitis, necrotizing enterocolitis, pulmonary fibrosis, severe hematologic disorders, hypersensitivity to auranofin or its components

## Interactions

### DRUGS

*phenytoin*: Possibly increased phenytoin level

## Adverse Reactions

**CNS:** Confusion, dizziness, EEG abnormalities, hallucinations, **seizures**

**EENT:** Gingivitis, glossitis, iritis or corneal ulcers from gold deposits in ocular tissue, metallic taste, stomatitis

**GI:** Abdominal cramps, anorexia, constipation, diarrhea, enterocolitis, flatulence, indigestion, jaundice, **melen**, nausea, vomiting

**GU:** Hematuria, elevated BUN and serum creatinine levels, proteinuria, vaginitis

**HEME:** **Agranulocytosis**, **aplastic anemia**, eosinophilia, **leukopenia**, **neutropenia**, **thrombocytopenia**

**RESP:** Cough, dyspnea, **fibrosis**, **interstitial pneumonitis**

**SKIN:** Alopecia, dermatitis, **exfoliative dermatitis**, photosensitivity, pruritus, rash, urticaria

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug is not recommended for use during pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- Drug is not recommended for use in mothers who are breastfeeding.

## Nursing Considerations

- Monitor blood and urine tests for signs of gold toxicity during auranofin therapy.

**WARNING** Know that gold toxicity may occur during treatment or several months afterward. It usually occurs with a cumulative dose of 400 to 800 mg and

may cause decreased hemoglobin level, WBC count less than  $4,000/\text{mm}^3$ , granulocyte count less than  $1,500/\text{mm}^3$ , platelet count less than  $150,000/\text{mm}^3$ , severe diarrhea, stomatitis, hematuria, proteinuria, pruritus, rash, severe diarrhea, and stomatitis.

- Monitor fluid intake and output imbalance. If urine output decreases, assess BUN and serum creatinine levels for signs of renal impairment.
- Notify prescriber about possible allergic reaction (dermatitis, pruritus, or rash). Drug may need to be discontinued.

## PATIENT TEACHING

- Advise patient that diarrhea is common but that he should notify prescriber immediately if it becomes severe.
- Tell patient to take drug exactly as prescribed and to have monthly blood tests.
- Inform patient that drug may take 3 to 4 months to reach a therapeutic level.
- Urge patient to report fatigue, skin problems, or stomatitis (possible blood dyscrasias).
- Tell patient to report bleeding gums, blood in stool or urine, and easy bruising.

**avanafil**

**Stendra**

## Class and Category

*Pharmacologic class:* Phosphodiesterase 5 (PDE5) inhibitor

*Therapeutic class:* Erectile dysfunction

## Indications and Dosages

➤ *To treat erectile dysfunction*

### **TABLETS**

**Adults.** 100 mg as early as 15 min before sexual activity or 50 mg as early as 30 min before sexual activity, as needed.  
*Maximum:* One dose daily.

***DOSAGE ADJUSTMENT*** Dosage may be increased to 200 mg as early as 15 min before sexual activity, as needed. For patient who is stable on alpha-blocker therapy or who is taking a moderate CYP3A4 inhibitor such as amprenavir, aprepitant, diltiazem, erythromycin, fluconazole, fosamprenavir, or verapamil, dosage is limited to 50 mg.

## Mechanism of Action

Enhances the effect of nitric oxide released in the penis through stimulation. Nitric oxide increases cGMP level, relaxes smooth muscle, and increases blood flow to the corpus cavernosum, thus producing an erection.

## Contraindications

Concomitant therapy with strong CYP3A4 inhibitors (including atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, and telithromycin) or riociguat, hypersensitivity to avanafil or its components, nitrate therapy

## Interactions

## DRUGS

*alpha blockers and other antihypertensives:* Increased risk of hypotension

*amlodipine, ritonavir:* Increased effect of avanafil with possible increased risk of adverse reactions

*CYP3A4 inhibitors:* Possibly increased plasma levels of avanafil

*guanylate cyclase stimulators such as riociguat:* Possibly increased risk of hypotension

*nitrates:* Profound hypotension

## ACTIVITIES

*alcohol use:* Increased risk of orthostatic hypotension

## Adverse Reactions

**CNS:** Depression, dizziness, fatigue, headache, insomnia, somnolence, vertigo

**CV:** **Abnormal ECG**, angina, **deep vein thrombosis**, hypertension, palpitations, peripheral edema

**EENT:** Epistaxis, eyelid swelling, hearing or vision loss, nasal or sinus congestion, nasopharyngitis, nonarteritic anterior ischemic optic neuropathy, oropharyngeal pain, sinusitis, tinnitus

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Constipation, diarrhea, dyspepsia, elevated liver enzymes, gastric pain, gastritis, gastroesophageal reflux disease, nausea, vomiting

**GU:** Hematuria, nephrolithiasis, pollakiuria, prolonged erection, urinary tract infection

**MS:** Arthralgia, back or musculoskeletal pain, muscle spasms, myalgia

**RESP:** Bronchitis, cough, exertional dyspnea, upper respiratory infection, wheezing

**SKIN:** Flushing, pruritus, rash

**Other:** Flu-like symptoms

## **Childbearing Considerations**

### **PREGNANCY**

- Not for use in women.

### **LACTATION**

- Not for use in women.

## **Nursing Considerations**

- Be aware that avanafil should not be used in a patient taking a strong CYP3A4 inhibitor (such as atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazadone, nelfinavir, ritonavir, saquinavir, telithromycin) because of increased risk of elevated avanafil levels that could cause serious adverse effects.
- Know that although nitrate therapy is a contraindication to avanafil therapy, in a life-threatening situation, at least 12 hours should elapse after the last dose of avanafil before nitrate administration is given. In this situation, be prepared to hemodynamically monitor the patient and expect hypotension to be treated, if it occurs.
- Use avanafil cautiously in a patient with preexisting cardiovascular disease because of the potential for increased cardiac adverse effects during sexual activity. Patient with left ventricular outflow obstruction or severely impaired autonomic control of blood pressure may be especially sensitive to the vasodilatation effect of avanafil.

- Use avanafil cautiously in the elderly and patients with mild to moderate renal or hepatic dysfunction. The effects of avanafil in the presence of severe renal or hepatic dysfunction is unknown.
- Monitor the patient's vision, especially in patients over age 50; who have diabetes, hypertension, coronary artery disease, or hyperlipidemia; or who smoke, because avanafil rarely may cause nonarteritic anterior ischemic optic neuropathy that may lead to decreased vision or permanent vision loss.

## PATIENT TEACHING

- Explain to patient that avanafil should be taken as early as 15 minutes before sexual activity and that sexual stimulation is required for drug to be effective.
- Remind patient that avanafil should not be taken more than once a day.

**WARNING** Warn patient not to take avanafil if he also takes any form of organic nitrate, either continuously or intermittently or other PDE5 inhibitors, because profound hypotension and death could result.

- Tell patient to stop taking drug and contact prescriber immediately if vision decreases suddenly in one or both eyes, or if he has a sudden loss of hearing, possibly with dizziness and tinnitus.
- Advise patient taking avanafil to seek sexual counseling to enhance the drug's effects.
- Instruct patient to notify prescriber immediately if erection is painful or lasts longer than 4 hours.
- Warn patient that alcohol ingestion may increase risk of low blood pressure, accompanied by dizziness when changing position, increased heart rate, and headache.

**avatrombopag**

**Doptelet**

## Class and Category

*Pharmacologic class: Thrombopoietin receptor agonist*

*Therapeutic class: hematopoietic*

## Indications and Dosages

- *To treat thrombocytopenia in patients with chronic liver disease who are scheduled to undergo a procedure*

### **TABLETS**

**Adults with a platelet count 40 to less than  $50 \times 10^9/\text{L}$ .** 40 mg once daily with food for 5 days starting 10 to 13 days prior to procedure and completed 5 to 8 days before procedure.

**Adults with a platelet count less than  $40 \times 10^9/\text{L}$ .** 60 mg once daily with food for 5 days starting 10 to 13 days prior to procedure and completed 5 to 8 days before procedure.

- *To treat thrombocytopenia in patients with chronic immune thrombocytopenia (ITP) who have had an insufficient response to a previous treatment*

### **TABLETS**

**Adults. Initial:** 20 mg once daily with food. If platelet count remains less than  $50 \times 10^9/\text{L}$  after 2 wk, dosage increased to 40 mg three times a wk and 20 mg on the remaining days of each wk. If platelet count remains less than  $50 \times 10^9/\text{L}$  after an additional 2 wk, dosage increased to 40 mg once daily. If platelet count following initial dosage is

between 200 and 400 x 10<sup>9</sup>/L after 2 wk, dosage decreased to 20 mg three times a wk. If platelet count remains between 200 and 400 x 10<sup>9</sup>/L after an additional 2 wk, dosage further decreased to 20 mg once weekly. *Maximum:* 40 mg once daily. *Discontinuation:* If platelet count does not increase to greater than or equal to 50 x 10<sup>9</sup>/L after 4 wks of dosing at maximum dose, drug discontinued. If platelet count is greater than 400 x 10<sup>9</sup>/L after 2 wk of dosing at 20 mg once weekly, drug discontinued.

***DOSAGE ADJUSTMENT*** For patients taking moderate or strong dual CYP2C9 and CYP3A4 inhibitors, initial dosage decreased to 20 mg three times a week. For patients taking moderate or strong dual CYP2C9 and CYP3A4 inducers, initial dosage increased to 40 mg once daily.

## Mechanism of Action

Stimulates differentiation and proliferation of megakaryocytes from bone marrow progenitor cells to increase platelet production.

## Contraindications

Hypersensitivity to avatrombopag or its components

## Interactions

### DRUGS

*moderate or strong dual inducers of CYP2C9 and CYP3A4:*

Possibly decreased effectiveness of avatrombopag

*moderate or strong dual inhibitors of CYP2C9 and CYP3A4:*

Possibly increased risk of avatrombopag toxicity

# Adverse Reactions

**CNS:** Fatigue, fever, headache

**CV:** Arterial/vein thromboembolism, peripheral edema, portal vein thrombosis

**EENT:** Epistaxis, gingival bleeding, nasopharyngitis

**GI:** Abdominal pain, nausea

**HEME:** Anemia

**MS:** Arthralgia, myalgia

**RESP:** Upper respiratory tract infection

**SKIN:** Bruise, petechiae

**Other:** **Hyponatremia**

# Childbearing Considerations

## PREGNANCY

- Drug may cause fetal harm.
- Use with caution and only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy and for 2 weeks after last dose.
- If drug is being given for brief periods, such as prior to an invasive procedure, breastfeeding must be interrupted, with breast milk pumped and discarded during drug therapy and for 2 weeks after last dose of drug.

# Nursing Considerations

- Expect to obtain a platelet count prior to starting avatrombopag therapy in patients with chronic liver disease undergoing a procedure and repeated on the day of the procedure to ensure that an adequate increase in platelet count has occurred.
- Be aware that patients with chronic immune thrombocytopenia should be prescribed the lowest dose needed to achieve and maintain a platelet count greater than or equal to  $50 \times 10^9$  as needed to reduce the risk for bleeding. The drug should not be used to normalize platelet counts.

**WARNING** Monitor patients for signs and symptoms of thromboembolic events and notify prescriber immediately if present, because avatrombopag increases thrombotic risk.

- Monitor patient's platelet counts weekly in patients with chronic immune thrombocytopenia until a stable platelet count greater than or equal to  $50 \times 10^9$  has been achieved, and then monthly thereafter. Platelet counts should be checked weekly for at least 4 weeks after drug is discontinued.

## **PATIENT TEACHING**

- Instruct patient with chronic liver disease undergoing a procedure to take avatrombopag beginning 10 to 13 days prior to procedure for 5 consecutive days only. Educate the patient on the importance of not missing doses. If a dose is missed instruct the patient to take it as soon as it is remembered but not to take two doses at the same time to make up for a missed dose. The next dose should be taken at the usual time the next day.

**WARNING** Review signs and symptoms of thrombotic conditions with patient. If present, stress importance of notifying prescriber and seeking emergency care immediately.

- Instruct patient to notify prescriber if taking any new medication, whether prescribed or over the counter, including herbal substances.
- Tell women of childbearing age to notify prescriber if pregnancy is suspected or confirmed.

- Advise women who are breastfeeding and receiving drug short term for a procedure to pump and discard breast milk during treatment and for 2 weeks following last dose of drug. Inform women wishing to breastfeed during chronic therapy that breastfeeding is not recommended.

## azathioprine

**Azasan, Imuran**

## azathioprine sodium

**Imuran I.V.**

### Class and Category

*Pharmacologic class:* Purine antagonist

*Therapeutic class:* Immunosuppressant, antirheumatic

### Indications and Dosages

➤ *To prevent kidney rejection after transplantation*

#### **TABLETS**

**Adults and children.** *Initial:* 3 to 5 mg/kg daily P.O. as a single dose on, or 1 to 3 days before, day of transplantation then decreased according to patient's response and tolerance to 1 to 3 mg/kg daily following surgery.

*Maintenance:* 1 to 3 mg/kg daily.

#### **I.V. INFUSION (IMURAN I.V.)**

**Adults unable to tolerate oral dosage.** *Initial:* 3 to 5 mg/kg as a single dose on, or 1 to 3 days daily before day of transplantation infused over 30 to 60 min, then decreased according to patient's response and tolerance to 1 to 3 mg/kg infused over 30 to 60 min daily following surgery until P.O. dose is tolerated (usually 1 to 4 days).

**DOSAGE ADJUSTMENT** Dosage reduced for patients with oliguria (as from tubular necrosis) after transplantation and in patients with heterozygous deficiency of nucleotide diphosphatase (NUDT15) or thiopurine S-methyl transferase (TPMT).

➤ *To reduce signs and symptoms of acute rheumatoid arthritis*

## TABLETS

**Adults.** *Initial:* 1 mg/kg (50 to 100 mg) daily as a single dose or twice daily for 6 to 8 wk. *Maintenance:* If initial therapy doesn't produce therapeutic effects or serious adverse effects after 6 to 8 wk, dosage increased every 4 wk by 0.5 up to 2.5 mg/kg/daily.

**DOSAGE ADJUSTMENT** Dosage reduced to 25% to 33% of usual dosage for patients who also take allopurinol.

Route	Onset	Peak	Duration
P.O., I.V.	4–8 wk	Unknown	Several days

## Mechanism of Action

May prevent proliferation and differentiation of activated B and T cells by interfering with purine (protein) and nucleic acid (DNA and RNA) synthesis.

## Contraindications

Hypersensitivity to azathioprine or its components,  
treatment of rheumatoid arthritis in pregnant women

## Interactions

### DRUGS

*ACE inhibitors and drugs that affect bone marrow and cell development in bone marrow, such as trimethoprim-sulfamethoxazole:* Possibly severe leukopenia

*cyclosporine:* Possibly decreased plasma cyclosporine level

*ribavirin:* Possibly induced severe pancytopenia and possibly increase risk of azathioprine-related myelotoxicity

*xanthine oxidase inhibitors such as allopurinol, febuxostat:* Increased plasma azathioprine levels possibly leading to azathioprine toxicity

*warfarin:* Possibly inhibited anticoagulant effect of warfarin

## Adverse Reactions

**CNS:** Fever, malaise, **progressive multifocal leukoencephalopathy**

**GI:** Abdominal pain, diarrhea, **hepatotoxicity**, nausea, **pancreatitis**, steatorrhea, vomiting

**HEME:** Immunosuppression (severe), leukopenia, macrocytic anemia, **pancytopenia**, **thrombocytopenia**

**MS:** Arthralgia, myalgia

**SKIN:** Acute febrile neutrophilic dermatosis (Sweet's syndrome), alopecia, **cancer**, rash

**RESP:** **Interstitial pneumonitis**

**Other:** Infection, **lymphomas and other neoplasms**, negative nitrogen balance

# Childbearing Considerations

## PREGNANCY

- Drug can cause fetal harm.
- Drug is contraindicated for use during pregnancy for treatment of rheumatoid arthritis.
- Use should be avoided to treat renal homotransplantation during pregnancy, if possible.

## LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug because of the potential risk for tumor formation in the infant.

## REPRODUCTION

- Women of childbearing age should be advised to avoid becoming pregnant during drug therapy.

# Nursing Considerations

- Obtain results of baseline laboratory tests, including WBC, RBC, and platelet counts. Expect to monitor results once a week during first month of therapy, twice a month during second and third months, and once a month or more thereafter.
- Know that hematologic reactions typically are dose-related and may occur late in therapy, especially in patients with transplant rejection.

**WARNING** Expect to reduce dosage or discontinue azathioprine, if WBC count decreases rapidly or remains significantly and consistently low.

**WARNING** Monitor patient closely for abnormal signs and symptoms suggestive of lymphomas, especially in

adolescent and young adult males who have a history of inflammatory bowel disease, in patients who have received a renal transplant, or in patients with rheumatoid arthritis, because the majority of patients who develop a lymphoma fall into one of these categories.

- Monitor liver enzymes, as ordered, for early signs of hepatotoxicity.
- Take action if patient develops thrombocytopenia, such as bleeding precautions, such as avoiding I.M. injections and venipunctures, applying ice to areas of trauma, and checking I.V. infusion sites every 2 hours for bleeding.
- Be aware that patients with low or absent thiopurine S-methyl transferase (TPMT) or nucleotide diphosphatase (NUDT15) levels are at risk for developing severe and life-threatening myelosuppression. Expect patient to be tested for these disorders if significant myelosuppression occurs. If confirmed, expect dosage to be decreased in the presence of heterozygous deficiency and drug discontinued in the presence of homozygous deficiency.
- Monitor the patient's prothrombin time if he also receives an oral anticoagulant.
- Be aware that azathioprine therapy increases risk of bacterial, fungal, protozoal, and viral infections. Watch for evidence of infection, such as fever, chills, sore throat, and mouth sores. Expect to administer aggressive antibiotic, antiviral, or other drug therapy and reduce azathioprine dosage.
- Minimize the risk of infection. If patient has severe leukopenia, take neutropenic precautions, such as placing him in a private room and limiting visitors.
- Know that rheumatoid arthritis requires at least 12 weeks of azathioprine therapy. During this time, continue other pain-relief measures, such as physical therapy, rest, and other drugs, such as salicylates and corticosteroids if it causes GI upset.
- Give oral azathioprine in divided doses or with meals if GI upset occurs.
- Expect to use lowest possible maintenance dosage for rheumatoid arthritis, reducing it gradually in 0.5-mg/kg (about 25-mg) increments at 4-week intervals, as ordered.

- Know that drug can be stopped abruptly, but its effects may persist several days.

## PATIENT TEACHING

- Advise patient to take oral drug with food or meals to minimize GI upset.

**WARNING** Teach patient to recognize and report signs of infection, such as sore throat and fever and to seek medical attention for any abnormal signs and symptoms that might be suggestive of a malignancy.

- Teach patient how to reduce the risk of bleeding and falling.
- Inform women of childbearing age to use effective contraception during drug therapy and not to breastfeed.

# azelastine hydrochloride

**Astelin, Astepro**

## Class and Category

*Pharmacologic class:* H<sub>1</sub>-receptor antagonist

*Therapeutic class:* Antihistamine

## Indications and Dosages

➤ *To treat symptoms of seasonal allergic rhinitis*

## NASAL SPRAY (ASTELIN)

**Adults and children age 12 and over.** 1 or 2 sprays in each nostril twice daily.

Alternatively, 2 sprays in each nostril once daily.

**Children age 5 to 11 years.** 1 spray in each nostril twice daily.

## **NASAL SPRAY (ASTEPRO)**

**Adults and children age 12 and over.** 1 or 2 sprays (0.1% or 0.15%) in each nostril twice daily. *Alternatively*, 0.15% solution may be administered as 2 sprays in each nostril once daily.

**Children age 6 to 11 years.** 1 spray (0.1% or 0.15%) in each nostril twice daily.

**Children age 2 to 5 years:** 1 spray (0.1%) in each nostril twice daily.

➤ *To treat symptoms of perennial allergic rhinitis*

## **NASAL SPRAY (ASTEPRO)**

**Adults and children age 12 and over.** 2 sprays (0.15%) in each nostril twice daily.

**Children age 6 to 11.** 1 spray (0.1% or 0.15%) in each nostril twice daily.

**Children age 6 months to 5 years:** 1 spray (0.1%) in each nostril twice daily.

➤ *To treat symptoms of vasomotor rhinitis*

## **NASAL SPRAY (ASTEPRO)**

**Adults and children age 12 and over.** 2 sprays in each nostril twice daily.

## **NASAL SPRAY (ASTELIN)**

**Adults.** 2 sprays in each nostril twice daily.

Route	Onset	Peak	Duration
Nasal	In 3 hr	Unknown	12 hr

## Mechanism of Action

Binds nonselectively to central and peripheral H<sub>1</sub> receptors, preventing histamine from reaching its site of action, which reduces or prevents most of histamine's physiologic effects. By blocking histamine at its site of action, azelastine inhibits GI, respiratory, and vascular smooth-muscle contraction; decreases capillary permeability, which reduces flares, itching, and wheals; and decreases lacrimal and salivary gland secretions.

## Contraindications

Hypersensitivity to azelastine or its components

## Interactions

### DRUGS

*cimetidine*: Possibly increased blood azelastine level

*CNS depressants*: Possibly increased sedative effects and reduced mental alertness

### ACTIVITIES

*alcohol use*: Possibly increased sedative effects and reduced mental alertness

## Adverse Reactions

**CNS:** Dizziness, fatigue, headache, somnolence

**CV:** Atrial fibrillation, palpitations

**EENT:** Bitter taste, dry mouth, epistaxis, nasal burning, paroxysmal sneezing, pharyngitis, rhinitis

**GI:** Nausea

**Other:** Weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Assess for changes in alertness, and take safety precautions, if needed.

### PATIENT TEACHING

- Teach patient how to use azelastine nasal spray properly to achieve maximum therapeutic effects.
- Instruct patient to prime pump before using for first time by placing his thumb on base and his index and middle fingers on shoulder area of bottle and then pressing thumb firmly and quickly against bottle four times, or until fine mist appears.
- Tell patient if he hasn't used spray in more than 3 days, he will need to reprime pump with two sprays or until fine mist appears.

- Advise patient to clear nostrils gently, if needed, before using spray.
- Teach patient to inhale deeply after each spray and then exhale through his mouth and tilt his head back so drug can spread over nasopharynx.
- Advise patient to store bottle upright and keep it tightly closed.

**WARNING** Emphasize that patient must consult prescriber before taking any OTC drug, such as cough syrup or a cold remedy, because of the risk of extreme CNS depression.

- Inform patient that decreased alertness may occur. Advise him to avoid hazardous activities or those that require alertness, such as driving or operating machinery, until drug's effects are known.
- Inform breastfeeding mothers to monitor infant for milk rejection because drug may cause a bitter taste in breast milk.

# azithromycin

## Zithromax

## azithromycin dihydrate

## Zmax

### Class and Category

*Pharmacologic class:* Macrolide

*Therapeutic class:* Antibiotic

### Indications and Dosages

- *To treat mild community-acquired pneumonia, otitis media, pharyngitis, tonsillitis, and uncomplicated skin and soft-tissue infections caused by susceptible bacteria*

## **ORAL SUSPENSION, TABLETS (AZITHROMYCIN)**

**Adults.** 500 mg as a single dose on day 1, followed by 250 mg daily on days 2 through 5.

**Children age 6 months and over with community-acquired pneumonia.** 10 mg/kg as a single dose (not to exceed 500 mg daily) on day 1, followed by 5 mg/kg (not to exceed 250 mg daily) daily on days 2 through 5.

**Children age 6 months and over with acute otitis media.** 30 mg/kg as a single dose. Alternatively, 10 mg/kg once daily for 3 days, or 10 mg/kg as a single dose on day 1 followed by 5 mg/kg on days 2 through 5.

**Children age 6 months and over with pharyngitis or tonsillitis:** 12 mg/kg once daily for 5 days.

- *To treat community-acquired pneumonia caused by *Chlamydophila pneumoniae*, *Haemophilus influenzae*, *Legionella pneumophila*, *Moraxella catarrhalis*, *Mycoplasma pneumoniae*, *Staphylococcus aureus*, or *Streptococcus pneumoniae* and requiring initial I.V. therapy*

## **ORAL SUSPENSION, TABLETS, I.V. INFUSION (ZITHROMAX)**

**Adults.** 500 mg I.V. (1 mg/ml concentration given over 3 hrs; 2 mg/ml concentration given over 1 hr) as a single dose daily for at least 2 days, followed by 500 mg P.O. as a single dose daily until patient completes 7 to 10 days of therapy.

- *To treat community-acquired pneumonia caused by C. pneumoniae, H. influenzae, M. pneumoniae, or S. pneumoniae*

## **E.R. ORAL SUSPENSION (ZMAX)**

**Adults and children weighing 34 kg (75 lb) or more.** 2 g as a single dose on an empty stomach.

**Children age 6 months and over weighing less than 34 kg (75 lb).** 60 mg/kg as a single dose on an empty stomach.

- *To treat acute bacterial sinusitis caused by Haemophilus influenzae, Moraxella catarrhalis, or Streptococcus pneumoniae*

## **ORAL SUSPENSION, TABLETS (AZITHROMYCIN)**

**Adults.** 500 mg once daily for 3 days

**Children age 6 months and over.** 10 mg/kg once daily for 3 days.

## **E.R. ORAL SUSPENSION (ZMAX)**

**Adults and children weighing 34 kg (75 lb) or more.** 2 g as a single dose on an empty stomach.

**Children age 6 months and over weighing less than 34 kg (75 lb).** 60 mg/kg as a single dose on an empty stomach

- *To treat acute bacterial exacerbations of COPD including chronic bronchitis caused by H. influenzae, M. catarrhalis, or S. pneumoniae*

## **ORAL SUSPENSION, TABLETS (AZITHROMYCIN)**

**Adults.** 500 mg daily for 3 days, or 500 mg as a single dose on day 1, followed by 250 mg daily on days 2 through 5.

- *To treat nongonococcal cervicitis and urethritis caused by Chlamydia trachomatis*

### **ORAL SUSPENSION, TABLETS (ZITHROMAX)**

**Adults.** 1 g as a one-time dose.

- *To treat urethritis or cervicitis caused by Neisseria gonorrhoeae*

### **ORAL SUSPENSION, TABLETS (AZITHROMYCIN)**

**Adults.** 2 g as a one-time dose.

- *To prevent Mycobacterium avium complex (MAC) in patients with advanced HIV infection*

### **ORAL SUSPENSION, TABLETS (ZITHROMAX)**

**Adults.** 1.2 g once weekly, as indicated.

*As adjunct to treat MAC in patients with advanced HIV infection*

### **ORAL SUSPENSION, TABLETS (ZITHROMAX)**

**Adults.** 600 mg daily in combination with ethambutol.

- *To treat pelvic inflammatory disease caused by Chlamydia trachomatis, Neisseria gonorrhoeae, or Mycoplasma hominis*

### **ORAL SUSPENSION, TABLETS, I.V. INFUSION (ZITHROMAX)**

**Adults.** 500 mg I.V. (1 mg/ml concentration given over 3 hrs; 2 mg/ml concentration given over 1 hr) as a single dose daily for 1 to 2 days, followed by 250 mg P.O. as a single dose daily until patient completes 7 days of therapy.

---

Route	Onset	Peak	Duration
-------	-------	------	----------

Route	Onset	Peak	Duration
P.O., I.V.	Varies	Unknown	Unknown

## Mechanism of Action

Binds to a ribosomal subunit of susceptible bacteria, blocking peptide translocation and inhibiting RNA-dependent protein synthesis. Drug concentrates in phagocytes, macrophages, and fibroblasts, which release it slowly and may help move it to infection sites.

## Incompatibilities

Don't add I.V. substances, additives, or drugs to azithromycin I.V. solution, and don't infuse through the same I.V. line.

## Contraindications

History of cholestatic jaundice or hepatic dysfunction associated with prior use of azithromycin; hypersensitivity to azithromycin, erythromycin, ketolide antibiotics, other macrolide antibiotics or their components

## Interactions

### DRUGS

*antacids that contain aluminum or magnesium:* Possibly decreased peak blood azithromycin level

*nelfinavir:* Possibly increased blood levels of these drugs

*oral anticoagulants such as warfarin:* Possibly potentiated effects of oral anticoagulants

*other macrolides:* Possible adverse effects

## FOODS

*any food*: Altered absorption rate of azithromycin

## Adverse Reactions

**CNS**: Aggressiveness, agitation, anxiety, asthenia, dizziness, fatigue, headache, hyperactivity, malaise, nervousness, paresthesia, **seizures**, somnolence, syncope, vertigo

**CV**: **Arrhythmias**, chest pain, edema, elevated serum CK level, **hypotension**, palpitations, **prolonged QT interval**, **torsades de pointes**, **ventricular tachycardia**

**EENT**: Hearing loss, oral candidiasis, perversion or loss of taste or smell, tinnitus, tongue discoloration

**ENDO**: Hyperglycemia

**GI**: Abdominal pain, anorexia, cholestatic jaundice, constipation, diarrhea, dyspepsia, elevated liver enzymes, flatulence, **hepatic necrosis or failure**, **hepatitis**, nausea, **pancreatitis**, pyloric stenosis, **pseudomembranous colitis**, vomiting

**GU**: **Acute renal failure**, elevated BUN and serum creatinine levels, nephritis, vaginal candidiasis

**HEME**: **Leukopenia**, **neutropenia**, **thrombocytopenia**

**MS**: Arthralgia

**SKIN**: Acute generalized exanthematous pustulosis, **erythema multiforme**, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other**: **Allergic reaction**, **anaphylaxis**, **angioedema**, **drug reaction with eosinophilia and systemic**

**symptoms (DRESS)**, elevated serum phosphorus level, **hyperkalemia**, infusion-site reaction (such as pain and redness), new or worsening myasthenia syndrome, superinfection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that azithromycin should not be used in patients with known QT prolongation, bradyarrhythmias, congenital long QT syndrome, uncompensated heart failure, or history of torsades de pointes; patients with ongoing proarrhythmic conditions such as uncorrected hypokalemia or hypomagnesemia, or significant bradycardia; or patients receiving drugs known to prolong the QT interval such as class IA (procainamide, quinidine) or class III (amiodarone, dofetilide, sotalol) antiarrhythmic agents because of increased risk of life-threatening arrhythmias such as torsades de pointes.
- Know that azithromycin should not be used in patients who have undergone donor stem cell transplant for cancer of the blood or lymph nodes because of an increased risk for cancer relapse and possibly death.
- Monitor elderly patients closely for arrhythmias because they are more susceptible to drug effects on the QT interval.
- Obtain culture and sensitivity test results, if possible, before starting therapy.

- Use azithromycin cautiously in patients with hepatic dysfunction not associated with prior use of azithromycin (drug is metabolized in the liver) or renal dysfunction (effects are unknown in this group).
- Give azithromycin capsules 1 hour before or 2 to 3 hours after food. Give tablets or suspension without regard to food.

**WARNING** Don't give azithromycin by I.V. bolus or I.M. injection because it may cause erythema, pain, swelling, tenderness, or other reaction at the site. Infuse it over 60 minutes or longer, as prescribed (typically 1 mg/ml over 3 hours or 2 mg/ml over 1 hour).

- Monitor liver enzymes closely in patients with impaired liver function and expect to discontinue the drug immediately if signs and symptoms of hepatitis occur.
- Assess patient for bacterial or fungal superinfection, which may occur with prolonged or repeated therapy. If it occurs, expect to give another antibiotic or antifungal.
- Monitor bowel elimination; if needed, obtain stool culture to rule out pseudomembranous colitis. If it occurs, expect to stop azithromycin and give fluid, electrolytes, and antibiotics effective with *Clostridium difficile*.
- Be aware that laboratory abnormalities may occur during azithromycin therapy. If present, alert prescriber, as changes can be reversible.

## PATIENT TEACHING

- Tell patient to take azithromycin capsules 1 hour before or 2 to 3 hours after food. Instruct patient to take tablets or suspension without regard to food.

**WARNING** Urge patient to consult prescriber before taking OTC drugs, including antacids. If they're prescribed, tell patient to take azithromycin 1 hour before or 2 to 3 hours after taking antacids. Also advise patient to inform prescriber of all prescriptions drugs being

taken, including over-the-counter and herbal preparations.

- Tell patient to report signs and symptoms of allergic reaction (such as rash, itching, hives, chest tightness, and trouble breathing) immediately.
- Warn patient that abdominal pain and loose, watery stools may occur. If diarrhea persists or becomes severe, urge him to contact prescriber and replace fluids.
- Teach patient to watch for and immediately report signs of superinfection, such as white patches in the mouth.

## aztreonam

### Azactam, Cayston

## Class and Category

*Pharmacologic class:* Monobactam

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To improve respiratory symptoms in cystic fibrosis patients with *Pseudomonas aeruginosa**

### INHALATION (CAYSTON)

**Adults and children age 7 and over.** 75 mg (1 vial) 3 times a day with doses at least 4 hr apart for 28 days (followed by 28 days off therapy).

- *To treat infections of the female reproductive tract; lower respiratory tract, skin, soft tissue, or urinary*

*tract; intra-abdominal infections; septicemia; and surgical abscesses caused by susceptible strains of gram-negative bacteria*

## **I.V. INFUSION, I.V. OR I.M. INJECTION (AZACTAM)**

**Adults with a urinary tract infection.** 500 mg or 1 g every 8 or 12 hours. I.V. bolus given slowly over 3 to 5 min. I.V. infusion given over 20 to 60 min.

**Adults with moderately severe systemic infections.** 1 or 2 g given every 8 to 12 hrs. I.V. bolus given slowly over 3 to 5 min. I.V. infusion given over 20 to 60 min.

**Adults with severe systemic or life-threatening infections.** 2 g every 6 or 8 hrs. I.V. bolus given slowly over 3 to 5 min. I.V. infusion given over 20 to 60 min.

*Maximum:* 8 g daily.

## **I.V. INFUSION OR INJECTION**

**Children ages 9 months and over with mild to moderate infections.** 30 mg/kg every 8 hr. *Maximum:* 120 mg/kg daily.

**Children ages 9 months and over with moderate to severe infections.** 30 mg/kg every 6 to 8 hr up to 120 mg/kg daily.

*Maximum:* 120 mg/kg/daily.

***DOSAGE ADJUSTMENT*** If creatinine clearance is 10 to 30 ml/min, initial dose is 1 to 2 g; then 50% of usual dose at usual interval. If creatinine clearance is less than 10 ml/min, initial dose is 500 mg to 2 g; then 25% of the usual dose every 6, 8, or 12 hr. For hemodialysis patients with serious or life-threatening infections, in addition to the maintenance doses, one-eighth of the initial dose given after each hemodialysis session.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
I.V. infusion	Immediate	Immediate	Unknown
I.V. injection	Immediate	Immediate	Unknown
I.M.	Variable	60 min	Unknown
Inhalation	Variable	60 min	Unknown

## **Mechanism of Action**

Inhibits bacterial cell wall synthesis in susceptible aerobic gram-negative bacteria. These bacteria assemble rigid, cross-linked cell walls in several steps. Aztreonam affects the final cross-linking step by inactivating penicillin-binding protein 3 (the enzyme that links cell wall strands), which causes cell lysis and death.

## **Incompatibilities**

Don't mix aztreonam in same I.V. solution as cephradine, metronidazole, or nafcillin sodium. Don't mix it in same I.M. injection solution as local anesthetic.

## **Contraindications**

Hypersensitivity to aztreonam or its components

## **Interactions**

### **DRUGS**

None reported

## **Adverse Reactions**

**CNS:** Confusion, dizziness, **encephalopathy**, fever, headache, insomnia, malaise, paresthesia, **seizures**, vertigo

**CV:** Chest pain, **hypotension**, transient ECG changes

**EENT:** Altered taste, diplopia, halitosis, mouth ulcers, mucocutaneous candidiasis, nasal congestion, sneezing, tinnitus, tongue numbness

**GI:** Abdominal cramps, diarrhea, elevated enzymes, **GI bleeding**, **hepatitis**, jaundice, nausea, **pseudomembranous colitis**, vomiting

**GU:** Breast tenderness, elevated serum creatinine level, vaginal candidiasis

**HEME:** Anemia, eosinophilia, leukocytosis, **neutropenia**, **pancytopenia**, positive Coombs' test, **prolonged PT and APTT**, **thrombocytopenia**, thrombocytosis

**MS:** Arthralgia, joint swelling, myalgia

**RESP:** **Bronchospasm**, dyspnea, wheezing

**SKIN:** Diaphoresis, **erythema multiforme**, **exfoliative dermatitis**, flushing, petechiae, pruritus, purpura, rash, **toxic epidermal necrolysis**, urticaria

**Other:** **Allergic reaction**, injection-site pain, phlebitis, swelling, or thrombophlebitis

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm although it does cross the placental barrier.
- Cystic fibrosis may increase the risk for preterm delivery.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Breastfeeding should be withheld during drug therapy when Azactam is used. Patient should check with prescriber before breastfeeding when Cayston is used.

## Nursing Considerations

- Obtain culture and sensitivity test results, if possible, before starting aztreonam therapy. If patient is acutely ill, expect to begin therapy before results are available.
- Keep in mind that other antimicrobials may be used with aztreonam in seriously ill patients at risk for gram-positive infection.
- Expect to use I.V. route for patients who need single doses over 1 g and those with life-threatening systemic infections, such as septicemia or peritonitis.
- Reconstitute aztreonam for I.V. bolus injection by using sterile water for injection. Immediately after adding diluent to vial, shake it vigorously to mix. After obtaining correct dose, discard unused solution. Reconstituted solution may turn light pink on standing at room temperature. This doesn't affect drug potency.
- Give I.V. bolus injection directly into I.V. tubing over 3 to 5 minutes.

**WARNING** Prepare aztreonam for I.V. infusion by using at least 50 ml of appropriate infusion solution per gram of aztreonam. Further dilute drug in I.V. solution, such as normal saline solution, D<sub>5</sub>W, dextrose 5% in normal saline solution, lactated Ringer's solution, or Ringer's solution.

- Know that I.V. infusion may be administered over 20 to 60 minutes.

- Flush I.V. tubing with a solution, such as normal saline solution, before and after administering I.V. infusion to reduce risk of incompatibilities.
- Know that if prescribed, mix aztreonam in same I.V. solution with other antibiotics (such as ampicillin sodium, cefazolin sodium, clindamycin phosphate, gentamicin sulfate, or tobramycin sulfate), or mix it with cloxacillin sodium and vancomycin hydrochloride in peritoneal dialysis solution.
- Prepare solution for I.M. injection using sterile or bacteriostatic water or sodium chloride for injection. Administer injection deep into large muscle, such as in dorsogluteal or ventrogluteal area.
- Dilute each vial of inhalation solution with 1 ampule of diluent that comes with the drug. To do so, open the glass medication vial carefully, remove metal ring by pulling the tab, and remove the gray rubber stopper. Twist the tip off the diluent ampule and squeeze the liquid into the glass medication vial. Replace the rubber stopper, then gently swirl the vial until contents have been completely dissolved. Administer immediately.
- Administer diluted inhalation solution using only an Altera Nebulizer System.
- Be aware that patient should use a bronchodilator prior to aztreonam inhalation therapy. A short-acting bronchodilator should be used at least 15 minutes before but no longer than 4 hours prior to aztreonam inhalation therapy, or a long-acting bronchodilator at least 30 minutes before but no longer than 12 hours prior to aztreonam inhalation therapy. If patient is receiving multiple inhaled therapies, administer the bronchodilator first, followed by mucolytics, and last of all aztreonam.
- Assess for signs of bacterial or fungal superinfection, which may occur with prolonged or repeated therapy. If superinfection occurs, treat it as prescribed.
- Monitor bowel elimination; if needed, obtain stool culture to rule out pseudomembranous colitis. If it occurs, expect to discontinue aztreonam and administer fluid, electrolytes, and antibiotics effective against *Clostridium difficile*.
- Evaluate patient's renal and liver function test results, as ordered, if patient has renal or hepatic impairment.
- Monitor renal function if patient is receiving an aminoglycoside because of the increased risk of nephrotoxicity.

## **PATIENT TEACHING**

- Emphasize the need to take full course of aztreonam exactly as prescribed, even if patient feels better before finishing it.
- Instruct patient how to dilute and administer inhalation form of drug, if ordered.
- Teach patient to recognize and immediately report signs and symptoms of allergic reactions, such as chest tightness, difficulty breathing, hives, itching, and rash.
- Warn patient that abdominal pain and loose, watery stools may occur 2 months or more after aztreonam therapy stops. If diarrhea persists or becomes severe, urge him to contact prescriber and replace fluids.
- Teach patient to watch for and immediately report signs of superinfection, such as white patches in mouth.

## B

# baloxavir marboxil

**Xofluza**

## Class and Category

*Pharmacologic class:* Polymerase acidic endonuclease inhibitor

*Therapeutic class:* Influenza antiviral

## Indications and Dosages

- *To treat acute uncomplicated influenza in patients who have been symptomatic for no more than 48 hours and who are otherwise healthy, or at high risk of developing influenza-related complications*

### **TABLETS**

**Adults and children 12 years and over weighing at least 80 kg (176 lb).** 80 mg as a single dose.

**Adults and children 12 years and over weighing 40 kg (88 lb) to less than 80 kg (176 lb).** 40 mg as a single dose.

## Mechanism of Action

Inhibits the endonuclease activity of the polymerase acidic protein, an influenza virus-specific enzyme required for viral gene transcription. This action prevents the influenza virus from being replicated.

## Contraindications

Hypersensitivity to baloxavir marboxil or its components

## Interactions

### DRUGS

*antacids, laxatives, oral supplements, and other polyvalent cation-containing products (e.g., calcium, iron, magnesium, selenium, or zinc):* Possibly decreased plasma concentrations of baloxavir which may reduce its effectiveness

*live attenuated intranasal influenza vaccine:* Possibly decreased effectiveness of vaccination

### FOODS

*calcium-fortified beverages, dairy products:* Possibly decreased effectiveness of baloxavir

## Adverse Reactions

**CNS:** Abnormal behavior, delirium, hallucinations, headache

**EENT:** Nasopharyngitis, sinusitis

**GI:** Bloody diarrhea, colitis, diarrhea, nausea, vomiting

**RESP:** Bronchitis

**SKIN:** **Erythema multiforme**, rash, urticaria

**Other:** **Anaphylaxis, anaphylactic shock, angioedema**

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Be aware that baloxavir is not effective in treating infections other than influenza.
- Know that baloxavir should be administered to patients who have had flu symptoms for no more than 48 hours.
- Do not administer baloxavir with calcium-fortified beverages, dairy products, or drugs that contain cation-containing products such as calcium, iron, magnesium, selenium, or zinc.

**WARNING** Monitor patient closely for hypersensitivity reactions that could be life threatening. Be prepared to provide emergency treatment per institutional protocol.

## PATIENT TEACHING

- Inform patient that baloxavir will be administered only once.
- Instruct patient that drug must not be taken with a calcium-fortified beverage or a meal containing dairy products. Also, tell patient to alert prescriber if he is taking any drugs that contain calcium, iron, magnesium, selenium, or zinc, because baloxavir may not be as effective when taken with such drugs.

# balsalazide disodium

**Colazal, Giazol**

## Class and Category

*Pharmacologic class:* Salicylate

*Therapeutic class:* Anti-inflammatory

## Indications and Dosages

➤ *To treat mildly to moderately active ulcerative colitis*

### **CAPSULES (COLAZAL)**

**Adults.** 2.25 g three times daily for up to 8 to 12 wk.

*Maximum:* 6.75 g daily for 12 wk.

**Children ages 5 to 17.** 750 mg or 2.25 g three times daily for up to 8 wk.

### **TABLETS (GIAZO)**

**Adults.** 3.3 g twice daily for up to 8 wk.

## Mechanism of Action

After it has been metabolized to 5-ASA, balsalazide may reduce inflammation by inhibiting the enzyme cyclooxygenase and decreasing production of arachidonic acid metabolites, which may be increased in patients with inflammatory bowel disease.

Cyclooxygenase is needed to form prostaglandin from arachidonic acid. Prostaglandin mediates inflammatory

activity and produces signs and symptoms of inflammation. By inhibiting prostaglandin synthesis, balsalazide may reduce signs and symptoms of inflammation in inflammatory bowel disease.

Balsalazide also interferes with leukotriene synthesis and inhibits the enzyme lipoxygenase. These substances are involved in the inflammatory response.

## Contraindications

Hypersensitivity to balsalazide, salicylates, or their components

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Fatigue, fever, headache, insomnia

**CV:** **Myocarditis**, **pericarditis**, vasculitis

**EENT:** Dry mouth, nasopharyngitis, pharyngitis, rhinitis, stomatitis

**GI:** Abdominal cramps or pain, anorexia, cirrhosis, constipation, diarrhea, dyspepsia, elevated liver enzyme levels, exacerbation of colitis, flatulence, **hepatotoxicity**, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Dysmenorrhea, interstitial nephritis, **renal failure**, UTI

**MS:** Arthralgia, myalgia

**RESP:** Alveolitis, cough, pleural effusion, pneumonia, respiratory tract infection

**SKIN:** Alopecia, pruritus

**Other:** **Anaphylaxis**, flu-like syndrome

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Monitor patients who are sensitive to olsalazine or sulfasalazine for possible cross-sensitivity to balsalazide.

- Monitor patients with pyloric stenosis for decreased or delayed drug effects due to prolonged gastric retention of balsalazide capsules.
- Monitor patient for possible exacerbation of colitis symptoms.

### PATIENT TEACHING

- Inform patient that balsalazide is used to reduce bowel inflammation and pain in ulcerative colitis and to minimize recurring inflammation.

- Instruct patient to swallow capsules whole, with a full glass of water, and not to chew or crush them.
- Advise patient to notify prescriber of any other drugs she may be taking, including herbal products, nutritional supplements, and OTC drugs, because they may interact with balsalazide.
- Instruct patient to notify prescriber immediately if colitis symptoms worsen.
- Inform patient that she can expect some improvement in symptoms in 3 to 21 days but that optimal results may take up to 6 weeks of treatment.

**baricitinib**

**Olumiant**

## Class and Category

*Pharmacologic class:* Janus kinase inhibitor

*Therapeutic class:* Antirheumatic

## Indications and Dosages

- *To treat moderate to severe active rheumatoid arthritis in patients who have had an inadequate response to one or more tumor necrosis factor (TNF) antagonist therapies*

### **TABLETS**

**Adults.** 2 mg once daily.

***DOSAGE ADJUSTMENT*** For patients with moderate renal impairment (estimated glomerular filtration rate between 30 and 60 ml/min) or patients taking strong organic anion

transporter 3 (OAT3) inhibitors such as probenecid, dosage reduced to 1 mg once daily. For patients who develop an absolute lymphocyte count (ALC) less than 500 cells/mm<sup>3</sup>, drug withheld until ALC is 500 cells/mm<sup>3</sup> or greater. For patients who develop an absolute neutrophil count (ANC) less than 1,000 cells/mm<sup>3</sup>, drug withheld until ANC is 1,000 cells/mm<sup>3</sup> or greater. For patients who develop a hemoglobin value less than 8 g/dl, drug withheld until hemoglobin is 8 g/dl or greater.

## **Mechanism of Action**

Janus kinases are intracellular enzymes that influence cellular processes of hematopoiesis and immune cell function. Janus kinase inhibitors interfere with these actions, thereby reducing the signs and symptoms of rheumatoid arthritis, which is thought to be an autoimmune disorder.

## **Contraindications**

Hypersensitivity to baricitinib or its components

## **Interactions**

### **DRUGS**

*Strong organic anion transporter 3 inhibitors, such as probenecid:* Increased baricitinib exposure, increasing risk of adverse reactions

*Live vaccines:* Decreased effectiveness of vaccine

## **Adverse Reactions**

**CV:** Elevated lipid levels, **thrombosis (including arterial and deep vein thrombosis)**

**GI:** Elevated liver enzymes, **gastrointestinal perforation**, nausea

**GU:** UTI

**HEME:** Anemia, **elevated platelet count**, **lymphopenia**, **neutropenia**

**MS:** Elevated creatine phosphokinase (CPK) levels

**RESP:** Bronchitis, pneumonia, **pulmonary embolus**, upper respiratory infections

**SKIN:** Acne, **nonmelanoma skin cancers**

**Other:** Infections such as bacterial, fungal (invasive), mycobacterial, viral, or other opportunistic infections; **lymphomas and other malignancies**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding should be avoided during drug therapy.

## Nursing Considerations

- Be aware that baricitinib should not be used in patients with an ALC less than 500 cells/mm<sup>3</sup>, ANC less than 1,000 cells/mm<sup>3</sup>, or hemoglobin level less than 8 g/dl.

- Know that baricitinib therapy should also be avoided in patients with an active, serious infection, including localized infections. In addition, drug is not recommended in patients with a glomerular filtration rate less than 30 ml/min or patients who have severe hepatic impairment.
- Test patients for latent tuberculosis, as ordered, prior to initiating baricitinib therapy. If positive, expect patient to receive treatment. Monitor all patients for signs and symptoms of tuberculosis throughout therapy, including patients who were negative for latent tuberculosis infection prior to initiating therapy. Know that tuberculosis therapy also may be prescribed for patients with a history of active or latent tuberculosis in whom an adequate course of treatment cannot be confirmed and for patients with a negative test for latent tuberculosis but who have risk factors for tuberculosis.
- Expect liver enzymes to be determined prior to baricitinib therapy and periodically throughout therapy, because drug can affect liver function. Know that if increases in liver enzymes occur and liver injury is suspected, drug therapy should be stopped until liver dysfunction is ruled out.
- Be aware that viral reactivation, including herpes zoster, may occur. If patient develops herpes zoster during therapy with baricitinib, expect drug therapy to be interrupted until the episode has been resolved. Know that patients should be screened for viral hepatitis before initiating therapy with baricitinib.
- Use baricitinib cautiously in patients who may be at increased risk for gastrointestinal perforation or thrombosis, as drug use may increase the risk for these life-threatening disorders.

**WARNING** Monitor patient's complete blood count closely, as drug may cause anemia, lymphopenia, or neutropenia. Expect drug to be withheld if patient develops an ALC less than 500 cells/mm<sup>3</sup> until ALC is 500 cells/mm<sup>3</sup> or greater; an ANC less than 1,000 cells/mm<sup>3</sup> until ANC is 1,000 cells/mm<sup>3</sup> or greater; or a hemoglobin value becomes less than 8 g/dl until the hemoglobin level is 8 g/dl or greater.

- Assess patient regularly for signs and symptoms of infection, because serious and sometimes fatal infections due to bacterial, invasive fungal, mycobacterial, viral, or other opportunistic pathogens may occur. Patients at higher risk are those who are taking immunosuppressants such as corticosteroids or methotrexate. Notify prescriber if infection is suspected

and expect antibiotic therapy to be prescribed, if confirmed. Know that baricitinib may be temporarily stopped if patient is not responding to antibiotic therapy and not restarted until the infection is under control.

- Be aware that baricitinib increases the risk of cancer. Assess the patient regularly, especially for nonmelanoma skin cancers.

**WARNING** Assess patient regularly for thrombosis, including arterial, deep venous thrombosis, and pulmonary embolism, as drug increases risk of thrombus formation.

- Monitor patient for new-onset abdominal symptoms, especially patients with a history of diverticulitis, because baricitinib increases the risk for gastrointestinal perforation.
- Monitor patient's lipid profile periodically, as ordered, during baricitinib therapy. Know that a lipid profile should be performed about 12 weeks into baricitinib therapy to determine if management of hyperlipidemia is needed.
- Avoid giving patient live vaccines during baricitinib therapy because drug may reduce effectiveness of the vaccination.

## PATIENT TEACHING

- Instruct patient to take baricitinib exactly as prescribed.
- Inform patient of her risk for infections. Review signs and symptoms of infection and stress importance of notifying prescriber if an infection is suspected or develops. Also tell patient that herpes zoster may also occur. Because it could become quite serious, it should be reported.
- Tell patient that baricitinib therapy increases the risk of certain cancers. Encourage her to report any unusual, persistent, or severe signs or symptoms to prescriber. Also instruct patient to periodically examine her skin for signs of skin cancer.
- Review signs and symptoms of a blood clot with patient and stress importance of seeking immediate medical attention if suspected.
- Alert patient that laboratory abnormalities such as an elevated lipid profile or liver enzymes may occur during baricitinib therapy and may require treatment. Stress importance of complying with ordered laboratory tests.

- Advise mothers not to breastfeed during treatment with baricitinib. Instruct women of childbearing age to report suspected or known pregnancy to prescriber, as fetal effects of baricitinib are unknown.
- Instruct patient not to receive vaccinations containing live virus during baricitinib therapy.

## beclomethasone dipropionate

### Beconase AQ, QVAR Redihaler

## Class and Category

*Pharmacologic class:* Corticosteroid

*Therapeutic class:* Antiasthmatic, anti-inflammatory

## Indications and Dosages

- *To maintain treatment of asthma as prophylactic therapy*

### ORAL INHALATION AEROSOL (QVAR)

**Adults and adolescents who are not on an inhaled corticosteroid.** *Initial:* 1 to 2 inhalations (40 to 80 mcg) twice daily, depending on strength used, approximately 12 hr apart. *Maximum:* 4 to 8 inhalations (up to 320 mcg) twice daily approximately 12 hr apart, depending on strength used.

**Adults and adolescents switching from another inhaled corticosteroid.** *Initial:* 1 to 4 inhalations (160

mcg) twice daily approximately 12 hr apart, depending on strength used previously. *Maximum:* 4 to 8 inhalations (up to 320 mcg) twice daily.

**Children ages 4 to 11.** 1 inhalation (40 mcg) twice daily, approximately 12 hr apart, increased after 2 wk to 2 inhalations (80 mcg) twice daily, approximately 12 hr apart, as needed. *Maximum:* 1 to 2 inhalations (80 mcg) twice daily.

➤ *To relieve symptoms of seasonal or perennial allergic and nonallergic (vasomotor) rhinitis; to prevent recurrence of nasal polyps after surgical removal*

## **NASAL SPRAY (BECONASE AQ)**

**Adults and children age 12 and over.** One or 2 inhalations (42 or 84 mcg) in each nostril twice daily for total dose of 168 or 336 mcg daily.

**Children ages 6 to 12.** *Initial:* 1 inhalation (42 mcg) in each nostril twice daily, increased to 2 inhalations (84 mcg) in each nostril twice daily, as needed with further increases in strength but no more than 2 inhalations per nostril, as needed. Once control is achieved, dosage decreased to 1 spray (42 mcg) in each nostril twice daily. *Maximum:* 336 mcg (2 inhalations in each nostril) daily given in two divided doses 12 hr apart.

## **Mechanism of Action**

May decrease number and activity of cells involved in the inflammatory response of allergies, asthma, and rhinitis, such as basophils, eosinophils, lymphocytes, macrophages, mast cells, and neutrophils. Also may inhibit production or secretion of chemical mediators, such as cytokines, eicosanoids, histamine, and leukotrienes. May produce

direct smooth-muscle cell relaxation and decrease airway hyperresponsiveness.

## Contraindications

Hypersensitivity to beclomethasone or its components, relief of acute bronchospasm or acute asthma, or status asthmaticus (QVAR)

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Aggression, depression, fatigue, fever, headache, insomnia, light-headedness, mania, psychomotor hyperactivity, sleep disorders, **suicidal ideation**

**CV:** Chest pain, tachycardia

**EENT:** Blurred vision, burning sensation in nasal passages, cataracts, central serous chorioretinopathy, dry mouth, dysphonia, earache, elevated intraocular pressure, epistaxis, glaucoma, hoarseness, lacrimation, loss of smell and taste, nasal congestion or ulceration, nasal septal perforation, nose and throat dryness and irritation, nose and oral candidiasis, pharyngitis, rhinorrhea, sinusitis, sneezing, unpleasant smell and taste

**ENDO:** **Adrenal insufficiency**, cushingoid symptoms

**GI:** Diarrhea, indigestion, nausea, **rectal hemorrhage**

**GU:** Dysmenorrhea, UTI

**MS:** Arthralgia, growth suppression in children (nasal aerosol)

**RESP:** Bronchitis, *bronchospasm*, chest congestion, cough, *pulmonary infiltrates*, upper respiratory tract infection, wheezing

**SKIN:** Acne, eczema, pruritus, rash, skin discoloration, urticaria

**Other:** *Anaphylaxis*, *angioedema*, flu-like symptoms, impaired wound healing, lymphadenopathy, weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that beclomethasone should not be used with patients who have experienced recent nasal septal ulcers, nasal surgery, or nasal trauma because of corticosteroids' adverse effects on wound healing.
- Know that if patient also takes an oral corticosteroid, expect to taper dosage slowly (by decreasing daily dosage or taking drug every other day, as ordered) about 1 week after beclomethasone therapy begins.

**WARNING** Be aware that when gradually switching patient from oral corticosteroid to inhaled beclomethasone,

watch for signs of life-threatening adrenal insufficiency, such as fatigue, hypotension, lassitude, nausea, vomiting, and weakness, during transition period and when exposed to infection, surgery, trauma, or other stressor. If signs occur, notify prescriber immediately.

- Expect to resume oral corticosteroid during a stressful period or severe asthma attack.
- Watch for signs of adrenal insufficiency during periods of stress because beclomethasone may be absorbed systemically.
- Be prepared, if patient has acute asthma attack or increased wheezing after receiving beclomethasone, to give a fast-acting bronchodilator, as prescribed. Expect to discontinue beclomethasone.
- Assess for signs of candidiasis, such as thick white coating or plaques on tongue and sides of mouth. Tell patient to rinse mouth with water without swallowing after inhalation; this may help to prevent oral candidiasis. If present, notify prescriber and expect to reduce dose or frequency or to stop beclomethasone. Also anticipate treatment with antifungal drug.
- Assess nasal discharge regularly when patient is prescribed nasal spray. Look for color or consistency changes, which may indicate infection when patient is using beclomethasone nasal spray.
- Monitor the growth of children receiving beclomethasone nasally.
- Monitor patients with a change in vision or a history of blurred vision, cataracts, glaucoma, or intraocular pressure because use of intranasal and inhaled corticosteroids may cause eye abnormalities. If adverse eye symptoms develop, notify prescriber and expect patient to be referred to an ophthalmologist.
- Monitor patient closely for altered thinking such as suicidal thoughts. If present, notify prescriber because drug will have to be discontinued.

## **PATIENT TEACHING**

- Advise patient not to abruptly stop taking beclomethasone because adrenal insufficiency may occur. Urge her to notify prescriber if she develops signs of adrenal insufficiency, such as anorexia, dizziness, dyspnea, fainting, fatigue, fever, hypotension, malaise, or nausea.
- Instruct her to prime pump before using nasal spray for first time by placing her thumb on its base, and her index and middle fingers on its

shoulder area (the canister should be on top, pointing down), and then pressing her thumb firmly and quickly against the bottle four times into the air away from eyes and face. If nasal spray has not been used for 7 consecutive days, remind patient that container needs to be primed by spraying two times prior to use. Before patient uses nasal inhalation canister for first time, instruct her to shake it and check that it's working properly by spraying it once in the air while looking for fine mist.

- Teach patient to inhale deeply after each nasal spray or inhalation, exhaling through mouth and tilting head back to let drug spread over the nasopharynx.
- Teach patient how to properly use oral inhalation aerosol, shaking canister well before using. If patient has trouble using device and coordinating inhalation with it, suggest using a spacer device.
- Advise patient prescribed two inhalations to wait a minute between them.
- Tell patient prescribed an inhaled bronchodilator with beclomethasone oral inhalation to use bronchodilator first, wait for 5 minutes, and then use beclomethasone.

**WARNING** Warn patient that beclomethasone isn't intended to relieve acute bronchospasm. Urge patient to notify prescriber if asthma symptoms don't respond.

- Advise patient to wear medical identification that states need for supplemental oral corticosteroids during severe asthma attack or stress. Inform patient that prescriber may order high-dose oral corticosteroid therapy.
- Warn patient and caretakers to report any abnormal thinking such as suicidal thoughts immediately to prescriber.

**WARNING** Caution patient to avoid exposure to chickenpox and measles because drug may cause immunosuppression. If she's exposed to these disorders, urge her to notify prescriber immediately.

- Tell patient to report any changes in vision to prescriber.

# belimumab

**Benlysta**

## Class and Category

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* Immunosuppressant

## Indications and Dosages

- *To treat active, autoantibody-positive systemic lupus erythematosus (SLE) in patients who are receiving standard therapy*

### I.V. INFUSION

**Adults and children age 5 and older.** 10 mg/kg infused over 1 hr every 2 wk for first 3 doses followed by 10 mg/kg infused over 1 hr every 4 wk.

### SUBCUTANEOUS INJECTION

**Adults.** 200 mg once wk injected into the abdomen or thigh.

**Adults transitioning from intravenous therapy.** 200 mg once wk injected into the abdomen or thigh, with first dose given 1 to 4 wk after the last I.V. dose.

## Mechanism of Action

Blocks the binding of soluble B-cell lymphocyte stimulator protein, a B-cell survival factor, to its receptors on B cells.

This action causes cell death, which helps to relieve the signs and symptoms of active, autoantibody-positive, systemic lupus erythematosus.

## Incompatibilities

Dextrose intravenous solutions are incompatible with belimumab.

## Contraindications

Hypersensitivity to belimumab or its components

## Interactions

### DRUGS

*Live virus vaccines:* Possibly suppressed immune response and increased adverse effects of vaccine

## Adverse Reactions

**CNS:** Anxiety, depression, fatigue, fever, headache, insomnia, migraines, myalgia, **progressive multifocal leukoencephalopathy, suicidal ideation**

**CV:** **Bradycardia, hypotension**

**EENT:** Nasopharyngitis, pharyngitis, sinusitis

**GI:** Diarrhea, nausea

**GU:** Cystitis, lupus nephritis, UTI

**HEME:** **Leukopenia**

**MS:** Extremity pain, myalgia

**RESP:** Bronchitis, dyspnea, pneumonia, upper respiratory tract infection

**SKIN:** Cellulitis, pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, antibelimumab antibody formation, flu-like symptoms, infusion reactions, injection site reactions (erythema, hematoma, induration, pain, pruritus), **malignancies**, serious infections

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-877-681-6296.
- Drug may cause fetal harm. Drug actively crosses placental barrier with largest amount transferred in the third trimester, which may affect fetal immune response in utero.
- Use with caution only if the benefit to the mother outweighs the potential risk to the fetus.
- Monitor neonate and infant if drug exposure occurred in utero for B-cell reduction and other immune dysfunction.

### LACTATION

- It is not clear if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### REPRODUCTION

- Women of childbearing age should avoid pregnancy by using effective contraception during drug therapy and for at least 4 months after final dose of the drug.

## Nursing Considerations

- Know that belimumab should not be used to treat patients who are receiving drug therapy to treat a chronic infection. Monitor patient closely for signs and symptoms of infections during belimumab therapy. If present, notify prescriber. If the infection is determined to be new, belimumab therapy may have to be interrupted until infection is resolved.
- Be aware that patient should be premedicated prior to receiving belimumab intravenously to prevent hypersensitivity and infusion reactions before each dose of belimumab. Patients with a history of multiple drug allergies or significant hypersensitivity may be at increased risk. If an infusion reaction still occurs, slow or temporarily stop the infusion, as ordered. If a serious hypersensitivity reaction occurs, discontinue drug immediately and notify prescriber. Know that a nonacute hypersensitivity reaction that may be evident as facial edema, fatigue, headache, myalgia, nausea, and rash may occur up to a week after an infusion.
- Remove vial for intravenous use from refrigerator and allow to stand 10 to 15 minutes prior to reconstitution. Use aseptic technique when reconstituting with 1.5 ml of sterile water for injection, USP for a 120-mg vial and 4.8 ml of sterile water for injection, USP when reconstituting a 400-mg vial. When injecting diluent solution into the vial, direct stream of sterile water toward the side of the vial to minimize foaming. Gently swirl the vial for 60 seconds every 5 minutes until the powder is dissolved. Do not shake or refrigerate during this process. It typically takes 10 to 15 minutes for powder to dissolve but may take as long as 30 minutes. Once reconstituted, protect from sunlight. When using a mechanical reconstitution device (swirler), do not exceed 500 rpm, and swirl no longer than 30 minutes.
- Use only 0.9% sodium chloride injection, USP (normal saline) to further dilute the drug being prepared for intravenous administration. Withdraw amount of normal saline from the infusion bag or bottle equivalent to the vial contents of reconstituted drug required for the patient's dose. Then add the required volume of the reconstituted solution of the drug into the infusion bag or bottle. Gently invert the bag or bottle to mix the solution. Discard any unused solution left in the vial(s). The solution should be stored in the refrigerator protected from direct sunlight, if not used immediately. Know that the total time from the drug being reconstituted to completion of infusion should not exceed 8 hours.
- Infuse belimumab intravenously over 1 hour separately from any other medication given concomitantly intravenously.
- Be aware that vials containing belimumab are intended for intravenous use only and autoinjectors and prefilled syringes are intended for subcutaneous use only.

- Know that the first subcutaneous injection of belimumab should be given under the supervision of a healthcare professional.
- Remove the autoinjector or prefilled syringe from the refrigerator and allow it to sit at room temperature for 30 minutes prior to administering. Do not warm the drug any other way. The solution should appear clear to opalescent and colorless to pale yellow. Discard if product exhibits discoloration or particulate matter or if the autoinjector or prefilled syringe is accidentally dropped on a hard surface. Use a different injection site each week; do not give the injection into areas where the skin is bruised, hard, red, or tender.

**WARNING** Monitor patient for a hypersensitivity reaction following administration of belimumab because hypersensitivity reactions, including anaphylaxis, may occur on the same day of infusion. Notify prescriber immediately if a reaction occurs, because death has occurred with some patients experiencing hypersensitivity reactions. Expect to provide emergency medical treatment as ordered and indicated by severity of reaction.

- Monitor African; American patients closely during belimumab therapy for decreased effectiveness, because clinical trials have shown the response rate may be lower in these patients.
- Watch for evidence of infection (such as cough, fever, malaise, pain) because patients receiving immunosuppressants such as belimumab are at increased risk for serious infections such as bronchitis, cellulitis, pneumonia, and urinary tract infection. If patient develops an infection, notify prescriber, monitor patient closely, and know that drug therapy may be interrupted until infection is gone.
- Be aware that other biologic therapies, such as B-cell targeted therapies or intravenous cyclophosphamide therapy, are not recommended during belimumab therapy because potential drug interactions are unknown.

## **PATIENT TEACHING**

- Instruct patient who will be self-injecting belimumab, as a subcutaneous injection, how to administer the injection and dispose of needle and syringe after injection.

- Tell patient to remove the autoinjector or prefilled syringe from the refrigerator and allow it to sit at room temperature for 30 minutes prior to administering. Tell patient not to warm the drug in any other way. Have patient inspect the solution. The solution should appear clear to opalescent and colorless to pale yellow. Instruct patient to discard if product exhibits discoloration or particulate matter or if the autoinjector or prefilled syringe is accidentally dropped on a hard surface. Tell patient to use a different injection site each week and not to give the injection into areas where the skin is bruised, hard, red, or tender.
- Advise patient that if a subcutaneous dose is missed, she should administer a dose as soon as she remembers. Then patient can resume dosing on the usual day of administration or start a new weekly schedule from the day that the missed dose was administered. Tell patient not to administer two doses on the same day.
- Instruct patient to report any signs of a hypersensitivity reaction such as difficulty breathing, hives, itching, or a rash to prescriber, and to seek medical attention immediately.
- Caution patient to report new or worsening depression, suicidal thoughts, or other mood changes.
- Tell patient to contact the prescriber if he develops new or worsening neurologic symptoms such as confusion, difficulty talking or walking, dizziness, loss of balance, memory loss, or vision problems.
- Advise patient not to receive any immunization with live vaccines for 30 days before or concurrently with belimumab and to avoid contact with anyone who has an infection.
- Tell female patient of childbearing age to use effective contraception during treatment and for at least 4 months after the final treatment because of potential adverse effects to infants exposed to drug in utero. Advise her to notify prescriber if pregnancy occurs and encourage her to enroll in the belimumab pregnancy registry.
- Encourage patient to report any persistent, severe, or unusual signs and symptoms to prescriber because drug may increase risk for cancer.

## benazepril hydrochloride

**Lotensin**

# Class and Category

*Pharmacologic class:* Angiotensin-converting enzyme (ACE) inhibitor

*Therapeutic class:* Antihypertensive

# Indications and Dosages

- *To control hypertension alone or with a thiazide diuretic*

## SUSPENSION, TABLETS

**Adults who aren't receiving a diuretic.** *Initial:* 10 mg daily. *Maintenance:* 20 to 40 mg daily as a single dose or in two equally divided doses.

**Adults who are receiving a diuretic.** 5 mg daily.

***DOSAGE ADJUSTMENT*** Initial dosage of 5 mg/day for adult patients with impaired renal function and creatinine clearance less than 30 ml/min; then increased gradually until blood pressure is controlled or dosage reaches maximum of 40 mg daily.

## SUSPENSION, TABLETS

**Children age 6 and over with glomerular filtration rate of 30 ml/min or higher.** *Initial:* 0.2 mg/kg daily. *Maximum:* 0.6 mg/kg daily or 40 mg daily.

Route	Onset	Peak	Duration
P.O.	1 hr	2-4 hr	24 hr

# Mechanism of Action

May reduce blood pressure by affecting renin-angiotensin-aldosterone system. By inhibiting angiotensin-converting enzyme, benazepril:

- prevents conversion of angiotensin I to angiotensin II, a potent vasoconstrictor that also stimulates aldosterone release
- may inhibit renal and vascular production of angiotensin II
- decreases serum angiotensin II level and increases serum renin activity. This decreases aldosterone secretion, slightly increasing serum potassium level and fluid loss.
- decreases vascular tone and blood pressure
- inhibits aldosterone release, which reduces sodium and water resorption, increases their excretion, and reduces blood pressure.

## Contraindications

Aliskiren therapy in patients with diabetes; concurrent therapy with a neprilysin inhibitor (e.g., sacubitril) or within 36 hours of switching to or from sacubitril/valsartan combination; history of angioedema; hypersensitivity to benazepril, other ACE inhibitors, or their components

## Interactions

### DRUGS

*aliskiren (in patients with diabetes or renal impairment), angiotensin receptor blockers, other ACE inhibitors:*

Increased risk of hyperkalemia, hypotension, and renal dysfunction

*antidiabetics (oral), insulin:* Possibly increased risk of hypoglycemia

*diuretics:* Possibly excessive hypotension

*gold salts:* Possibly nitritoid reaction including facial flushing, hypotension, nausea, and vomiting

*lithium*: Increased serum lithium level and risk of lithium toxicity

*mTOR inhibitors (everolimus, sirolimus, temsirolimus)*,

*neprilysin inhibitors*: Increased risk for angioedema

*NSAIDs*: Possible decreased renal function in patients who are elderly, volume-depleted, or have a compromised renal function; may increase antihypertensive effect of benazepril

*potassium preparations, potassium-sparing diuretics*:

Possibly increased serum potassium level

## Adverse Reactions

**CNS**: Anxiety, asthenia, dizziness, drowsiness, fatigue, headache, hypertonia, insomnia, nervousness, paresthesia, sleep disturbance, somnolence, syncope, weakness

**CV**: Angina, **ECG changes**, **hypotension**, orthostatic hypotension, palpitations, peripheral edema

**EENT**: Sinusitis

**ENDO**: Hyperglycemia

**GI**: Abdominal pain, **acute liver failure**, **cholestatic hepatitis**, constipation, elevated liver enzymes, gastritis, **hepatic necrosis**, **melen**a, nausea, **pancreatitis**, small bowel angioedema, vomiting

**GU**: **Acute renal failure**, decreased libido, elevated BUN and serum creatinine levels, frequent urination, impotence, **nephrotic syndrome**, oliguria, **progressive azotemia**, proteinuria, **renal insufficiency**, UTI

**HEME**: **Agranulocytosis**, decreased hemoglobin level, **hemolytic anemia**, **leukopenia**, **neutropenia**, **thrombocytopenia**

**MS**: Arthralgia, arthritis, myalgia

**RESP:** ACE cough, **asthma**, bronchitis, **bronchospasm**, dyspnea

**SKIN:** Alopecia, dermatitis, diaphoresis, flushing, pemphigus, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**

**Other:** **Anaphylaxis**, **angioedema**, **hyperkalemia**, **hyponatremia**

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm, especially during the second and third trimesters of pregnancy.
- Oligohydramnios that occurs in pregnant women as a result of the drug can cause reduced fetal renal function leading to anuria and renal failure, fetal lung hypoplasia, and skeletal deformations, including skull hypoplasia. In addition, hypotension and death may occur.
- Drug should not be given during pregnancy and drug should be discontinued as soon as possible if pregnancy occurs.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### REPRODUCTION

- Women of childbearing age should be advised to avoid pregnancy by using effective contraception during drug therapy.

## Nursing Considerations

- Evaluate blood pressure with patient lying down, sitting, and standing before starting benazepril and then regularly, as appropriate, to monitor effectiveness.
- Monitor urine output and BUN and serum creatinine levels, as needed, before therapy and then during therapy, especially in patients with renal artery stenosis, severe heart failure, postmyocardial infarction or in patients who are volume depleted. Also monitor patients closely who are also receiving NSAID or angiotensin receptor blocker therapy because these patients may be at increased risk for developing acute renal failure.

**WARNING** Monitor patient closely during dialysis because sudden and potentially life-threatening anaphylactoid reactions have occurred in some patients dialyzed with high-flux membranes while receiving an ACE inhibitor like benazepril. If anaphylaxis occurs, institute emergency measures, as ordered, and stop dialysis.

- Monitor liver enzymes regularly, as ordered. Assess patient routinely for signs and symptoms of liver dysfunction, such as jaundice and fatigue. Notify prescriber if patient develops jaundice or exhibits elevated liver enzyme levels, as drug will need to be discontinued.

**WARNING** Be alert for angioedema, especially after first dose. If it extends to larynx and patient has laryngeal stridor or signs of airway obstruction, prepare to give epinephrine subcutaneously immediately, as prescribed, and discontinue benazepril. Be aware that black patients have a higher incidence of angioedema compared to nonblacks.

- Monitor WBC count periodically to detect neutropenia and agranulocytosis.
- Check serum potassium and other electrolyte levels to detect electrolyte imbalances.
- Take safety precautions, such as having patient change positions slowly and sit on edge of bed before arising to prevent injury caused by orthostatic hypotension.

## PATIENT TEACHING

- Teach patient how to monitor blood pressure, if appropriate, and how to recognize signs of hypertension and hypotension.

**WARNING** Urge patient to contact prescriber before using any OTC salt substitutes, which may contain potassium, or potassium supplements. These substances increase the risk of hyperkalemia.

- Explain that a persistent dry cough may develop and may not subside unless benazepril is stopped. If cough becomes bothersome or interferes with sleep or activities, patient should notify prescriber.

**WARNING** Instruct patient to contact prescriber immediately if she has signs of angioedema, such as swelling of the face, eyes, lips, or tongue.

- Caution patient to avoid sudden position changes and to rise slowly from sitting or lying to minimize orthostatic hypotension.

**WARNING** Advise patient to stop benazepril and notify prescriber as soon as possible if she experiences syncope.

**WARNING** Caution women of childbearing age to use reliable contraception and to notify prescriber immediately if pregnancy is suspected. Benazepril may cause fetal harm and should be discontinued.

# benralizumab

## Fasenra

# Class and Category

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* Antiasthmatic

## Indications and Dosages

- *To treat severe asthma as an add-on maintenance treatment in patients with eosinophilic phenotype*

### SUBCUTANEOUS INJECTION

**Adults and children age 12 and over.** 30 mg once every 4 wk for the first 3 doses, then once every 8 wk.

## Mechanism of Action

Binds to the alpha subunit of the human interleukin-5 receptor, which is expressed on the surface of basophils and eosinophils. Eosinophils play a part in the inflammatory process, which is present in the pathogenesis of asthma. When binding to the interleukin-5 receptor occurs, eosinophils are reduced through an antibody-dependent cell-mediated cytotoxicity to help relieve inflammation found in asthma.

## Contraindications

Hypersensitivity to benralizumab or its components

## Interactions

### DRUGS

None reported

# Adverse Reactions

**CNS:** Fever, headache

**EENT:** Pharyngitis

**SKIN:** Rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, benralizumab antibody formation, injection-site reactions (erythema, pain, papule, pruritus)

# Childbearing Considerations

## PREGNANCY

- Pregnancy exposure registry: 1-877-311-8972 or [mothertobaby.org/Fasenra](http://mothertobaby.org/Fasenra).
- Drug may cause fetal harm. Drug actively crosses placental barrier with largest amount transferred in the third trimester and may affect fetal immune response in utero.
- Use cautiously only if the benefit to the mother outweighs the potential risk to the fetus.

## LACTATION

- It is not clear if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Expect to treat patients with preexisting parasitic (helminth) infections before benralizumab therapy is begun, because it is not known if the drug will influence a patient's response to treatment for such an infection. If patient develops a parasitic infection while taking benralizumab and does not respond to treatment, expect benralizumab to be discontinued until the infection is resolved.

**WARNING** Know that benralizumab should never be used to treat acute asthma symptoms, acute bronchospasms, acute exacerbations of asthma, or status asthmaticus.

- Warm benralizumab by leaving carton at room temperature for about 30 minutes before administration. Grasp the syringe body, not the plunger, to remove the prefilled syringe from the tray. Inspect the solution, which should appear clear to opalescent, colorless to slightly yellow, and may contain a few translucent or white to off-white particles. The syringe may contain a small air bubble, which is normal. If present, do not expel the air bubble prior to administration. Do not remove needle cover until ready to give the injection subcutaneously. When ready, hold the syringe body and remove the needle cover by pulling straight off. Do not hold the plunger or plunger head while removing the needle cover or the plunger may move.
- Inject benralizumab subcutaneously into the abdomen, thigh, or upper arm. Inject all the drug by pushing in the plunger all the way until the plunger head is completely between the needle guard activation clips. This is necessary to activate the needle guard. After injection, maintain pressure on the plunger head and remove the needle from the skin. Release pressure on the plunger head to allow the needle guard to cover the needle. Do not recap the syringe. Discard the used syringe into a sharps container.

**WARNING** Monitor patient closely for hypersensitivity reactions that may occur within hours after benralizumab has been administered. If present, notify prescriber, provide supportive emergency care, and expect drug to be discontinued.

- Expect inhaled or systemic corticosteroids used to treat asthma to be gradually withdrawn, if no longer needed. Corticosteroid therapy should never be withdrawn abruptly.

## **PATIENT TEACHING**

- Teach patient and caregivers how to use the autoinjector (Fasenra Pen), if prescribed, by using the “Instructions for Use” that comes with it. Also teach patient how to administer a subcutaneous injection using the autoinjector. Tell patient to inject the drug either into the abdomen or thigh. A caregiver may also use the upper arm.

- Instruct patient that benralizumab is not effective in treating acute asthma symptoms or acute exacerbations. If asthma remains uncontrolled or worsens after benralizumab therapy is begun, tell patient to notify prescriber or seek emergency medical care.

**WARNING** Tell patient to report any signs of an allergic reaction such as difficulty breathing, hives, or rash immediately. Remind patient that although an allergic reaction usually occurs within hours after benralizumab is administered, a delayed reaction could occur even days later.

- Emphasize importance of not decreasing any prescribed inhaled or systemic corticosteroid dosage without prescriber knowledge.

## benztropine mesylate

### Cogentin

## Class and Category

*Pharmacologic class:* Anticholinergic

*Therapeutic class:* Antiparkinsonian, central-acting anticholinergic

## Indications and Dosages

➤ *As adjunct, to treat all forms of Parkinson's disease*

### **TABLETS, I.M. OR I.V. INJECTION**

**Adults with Parkinson's disease.** *Initial:* 0.5 to 1 mg daily, increased gradually in increments of 0.5 mg as

needed. *Maximum*: 6 mg daily.

**Adults with idiopathic Parkinson's disease.** *Initial*: 0.5 to 1 mg at bedtime. *Maximum*: 4 to 6 mg daily.

**Adults with postencephalitic Parkinson's disease.**

*Initial*: 0.5 mg to 2 mg at bedtime and then increased as needed. *Maximum*: 6 mg daily.

- *To control extrapyramidal symptoms (except tardive dyskinesia) caused by phenothiazines and other neuroleptics*

## **TABLETS, I.M. OR I.V. INJECTION**

**Adults.** 1 to 4 mg once or twice daily.

- *To treat acute dystonic reactions*

## **TABLETS, I.M. OR I.V. INJECTION**

**Adults.** *Initial*: 1 to 2 ml (1 to 2 mg total dose) I.V. or I.M.

*Maintenance*: 1 to 2 mg P.O. twice daily to prevent recurrence.

Route	Onset	Peak	Duration
P.O.	1-2 hr	Unknown	24 hr
I.V., I.M.	15 min	Unknown	24 hr

## **Mechanism of Action**

Blocks acetylcholine's action at cholinergic receptor sites. This restores the brain's normal dopamine and acetylcholine balance, which relaxes muscle movement and decreases drooling, rigidity, and tremor. Benztropine also may inhibit dopamine reuptake and storage, which prolongs dopamine's action.

# Contraindications

Children younger than age 3, hypersensitivity to benztropine mesylate or its components

# Interactions

## DRUGS

*amantadine, phenothiazines, tricyclic antidepressants:*

Possibly increased adverse anticholinergic effects

*haloperidol:* Possibly decreased haloperidol effects and development of tardive dyskinesia

# Adverse Reactions

**CNS:** Agitation, confusion, delirium, delusions, depression, disorientation, dizziness, drowsiness, euphoria, excitement, fever, hallucinations, headache, light-headedness, listlessness, memory loss, nervousness, paranoia, psychosis, weakness

**CV:** **Hypotension**, mild bradycardia, orthostatic hypotension, palpitations, tachycardia

**EENT:** Blurred vision, diplopia, dry mouth, increased intraocular pressure, mydriasis, narrow-angle glaucoma, suppurative parotitis

**GI:** Constipation, duodenal ulcer, epigastric distress, ileus, nausea, vomiting

**GU:** Dysuria, urinary hesitancy, urine retention

**MS:** Muscle spasms, muscle weakness

**SKIN:** Decreased sweating, dermatoses, flushing, rash, urticaria

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding as drug may suppress lactation.

# Nursing Considerations

- Expect to administer I.V. or I.M. benztropine when patient needs more rapid response than oral drug can provide. Be aware that I.M. route is commonly used because it provides effects in about the same time as I.V. route. Watch for improvement a few minutes after administration. If parkinsonian symptoms reappear, expect to repeat dose, as ordered.
- Know that therapy typically begins with a low dose followed by gradual increases of 0.5 mg every 5 or 6 days because benztropine has a cumulative action.
- Assess muscle rigidity and tremor at baseline. Then monitor them often for improvement, which indicates drug's effectiveness.
- Give drug before or after meals based on patient's need and response. If patient has increased salivary secretions, expect to administer benztropine after meals. If patient has dry mouth, plan to give drug before meals unless nausea develops.

**WARNING** Know that when giving drug to patient with drug-induced extrapyramidal reactions, watch for worsening psychiatric symptoms.

- Monitor patient's movements closely. High-dose benztropine therapy may cause weakness and inability to move specific muscle groups. If this occurs, expect to reduce benztropine dosage.

## PATIENT TEACHING

- Warn patient that drug has a cumulative effect, increasing risk of adverse reactions and overdose.
- Caution against driving and similar activities until benztropine's effects are known because it may cause blurred vision, dizziness, or drowsiness.

**WARNING** Know that because benztropine decreases sweating, urge patient to avoid extremely hot or humid conditions to reduce risk of heatstroke and severe hyperthermia. This is especially important for elderly patients and those who abuse alcohol or have chronic illness or CNS disease.

- Stress need for periodic eye examinations and intraocular pressure measurements because drug may cause narrow-angle glaucoma and increase intraocular pressure.

## bethanechol chloride

**Duvoid, Urecholine**

## Class and Category

*Pharmacologic class:* Cholinergic agonist

*Therapeutic class:* Urinary tract stimulant

## Indications and Dosages

- *To treat acute postoperative and postpartum nonobstructive urine retention and retention caused by neurogenic atony of bladder*

## **TABLETS**

**Adults.** 10 to 50 mg three times daily or four times daily.  
*To determine minimum effective dose:* 5 to 10 mg repeated every hour until response is obtained or maximum of 50 mg is reached.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.	30-90 min	60 min	6 hr
SubQ	5-15 min	15-30 min	2 hr

## **Mechanism of Action**

Acts directly on muscarinic receptors of the parasympathetic nervous system, increasing detrusor muscle tone in the bladder and allowing contraction strong enough to start voiding. Like natural neurotransmitter acetylcholine, bethanechol stimulates gastric motility, increases gastric tone, and enhances peristalsis.

## **Contraindications**

Acute inflammatory lesions of GI tract, bronchial asthma, coronary artery disease, epilepsy, hypersensitivity to bethanechol or its components, hyperthyroidism, marked vagotonia, mechanical obstruction of GI or GU tract, Parkinson's disease, peptic ulcer disease, peritonitis, pronounced bradycardia or hypotension, questionable integrity of GI or GU mucosa, spastic GI disorders, vasomotor instability

# Interactions

## DRUGS

*cholinergic drugs*: Possibly increased effects of bethanechol

*ganglionic blockers*: Possibly severe hypotension, usually first manifested by severe adverse GI reactions

*procainamide, quinidine*: Possibly decreased effects of bethanechol

## Adverse Reactions

**CNS**: Headache, malaise

**CV**: **Hypotension** with reflex tachycardia, vasomotor response

**EENT**: Excessive salivation, lacrimation, miosis

**GI**: Abdominal cramps, colicky pain, diarrhea, eructation, nausea, vomiting

**GU**: Urinary urgency

**RESP**: **Asthma attack, bronchoconstriction**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.

- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Assess urine elimination before starting bethanechol therapy.

**WARNING** Be aware that patient must have functioning urinary sphincter because a sphincter that doesn't relax when bladder contracts can push urine upward into renal pelvis and cause reflux infection.

- Give oral bethanechol 1 hour before or 2 hours after meals to reduce risk of nausea and vomiting.

## PATIENT TEACHING

- Advise patient to take bethanechol on an empty stomach 1 hour before or 2 hours after meals to reduce risk of nausea and vomiting.

**betrixaban**

**Bevyxxa**

## Class and Category

*Pharmacologic class:* Factor Xa inhibitor

*Therapeutic class:* Antithrombotic

## Indications and Dosages

- *To prevent venous thromboembolism (VTE) in patients hospitalized for an acute medical illness who are at risk for thromboembolic complications due to moderate or severe restricted mobility and other risk factors for VTE*

## CAPSULES

**Adults.** *Initial:* 160 mg, followed by 80 mg once daily for 35 to 42 days.

***DOSAGE ADJUSTMENT*** For patient with severe renal impairment who has a creatinine clearance less than 30 ml/min but greater than 15 ml/min or who is starting or receiving concomitant P-gp inhibitors, initial dose is reduced to 80 mg, followed by 40 mg once daily.

Route	Onset	Peak	Duration
P.O.	Unknown	3-4 hr	72 hr or more

## Mechanism of Action

Selectively blocks the active site of FXa to inhibit free FXa and prothrombinase activity. This decreases thrombin formation.

## Contraindications

Active pathological bleeding, hypersensitivity to betrixaban or its components

## Interactions

## DRUGS

*anticoagulants, antiplatelets, thrombolytics*: Possibly increased risk of bleeding

*P-gp inducers such as carbamazepine, phenytoin, rifampin, St. John's wort*: Possibly decreased effectiveness of betrixaban

*P-gp inhibitors such as amiodarone, azithromycin, clarithromycin, ketoconazole, verapamil*: Increased effects of betrixaban with possible increased adverse reactions

## Adverse Reactions

**CNS**: Headache, **intracranial hemorrhage**, intraspinal bleeding

**CV**: Hypertension, **pericardial bleeding**

**EENT**: Epistaxis, intraocular bleeding

**GI**: Constipation, diarrhea, **gastrointestinal bleeding**, nausea, **retroperitoneal bleeding**

**GU**: Hematuria, UTI

**HEME**: **Major** and minor **bleeding events**

**MS**: Intra-articular bleeding, intramuscular bleeding with compartment syndrome

**Other**: **Hypersensitivity reaction**, **hypokalemia**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm. However, drug has the potential to increase risk of hemorrhage during pregnancy.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LABOR & DELIVERY

- Drug has the potential to increase risk of hemorrhage during delivery.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that patients with severe renal impairment taking P-gp inhibitors should not receive betrixaban nor should patients receiving P-gp inducers regardless of renal function. Also patients with moderate to severe hepatic impairment or who have any hepatic disease associated with coagulopathy should not be given betrixaban.
- Monitor patient closely for bleeding, which can range from minor bleeding to hemorrhage. Be aware the use of drugs that affect hemostasis, such as anticoagulants, antiplatelets like aspirin, heparin, nonsteroidal anti-inflammatory drugs, other anticoagulants, selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors, and thrombolytics, increase the risk of bleeding. Notify prescriber immediately if bleeding occurs and expect drug to be discontinued if bleeding is significant. Be aware that there is no treatment to stop the anticoagulant effect of betrixaban and that its effect can persist for at least 72 hours after the last dose.

**WARNING** Know that an epidural catheter should not be removed earlier than 72 hours after betrixaban has been administered because of the risk of intraspinal bleeding, which can result in long-term or permanent paralysis. Monitor patient receiving epidural or spinal anesthesia or puncture frequently for signs and symptoms of neurological impairment, such as bladder or bowel dysfunction, numbness, or weakness in legs. Be aware that prompt diagnosis and treatment are crucial if any neurological abnormalities occur.

- Monitor patient with severe renal dysfunction closely because of increased risk of bleeding and report any bleeding immediately.

## PATIENT TEACHING

- Tell patient if he misses a dose to take it as soon as possible on the same day. Remind him that the dose should not be doubled to make up for a missed dose.
- Instruct patient to watch for any signs and symptoms of bleeding and to report them immediately and seek emergency care.
- Tell patient to notify prescriber of any new medication, including over-the-counter drugs, before taking them.
- Stress importance of telling all doctors about betrixaban use, especially prior to procedures or surgery in which epidural or spinal anesthesia will be used.

# bezlotoxumab

## Zinplava

## Class and Category

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* *Clostridium difficile* recurrence inhibitor

## Indications and Dosages

- *To reduce recurrence of Clostridium difficile infection (CDI) in patients who are receiving antibacterial drug treatment for CDI and are at a high risk for CDI recurrence*

## **I.V. INFUSION**

**Adults.** 10 mg/kg given over 60 min as a single dose.

## **Mechanism of Action**

Binds to *C. difficile* toxin B and neutralizes its effects.

## **Incompatibilities**

Do not administer simultaneously through the same I.V. line with any other drugs.

## **Contraindications**

Hypersensitivity to bezlotoxumab or its components

## **Interactions**

### **DRUGS**

None reported

## **Adverse Reactions**

**CNS:** Dizziness, fatigue, fever, headache

**CV:** **Heart failure**, hypertension, **ventricular tachyarrhythmia**

**GI:** Nausea

**RESP:** Dyspnea

**Other:** Antibezlotoxumab antibodies, infusion-related reactions

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Be aware that bezlotoxumab alone is not to be used to treat *C. difficile* infection (CDI), as it is not an antibacterial drug. It should only be used in conjunction with antibacterial drug treatment of CDI.
- Use with extreme caution in patients with a history of congestive heart failure, as drug may exacerbate congestive heart failure and may become severe enough to cause death.
- Dilute bezlotoxumab prior to administering. Withdraw the required volume from the drug vial based on the patient's weight in kg and transfer into an intravenous bag containing either 0.9% sodium chloride injection USP or 5% dextrose injection USP to prepare a diluted solution with a final concentration ranging from 1 to 10 mg/ml. Mix diluted solution by gentle inversion. Do not shake.
- Store diluted solution at room temperature up to 15 hours or under refrigeration for up to 23 hours prior to administration. If refrigerated, allow the intravenous bag to come to room temperature before administering but do not allow total time following mixture and including administration to exceed 16 hours if kept at room temperature or 24 hours if refrigerated.
- Administer as an intravenous infusion over 60 minutes using a sterile, nonpyrogenic, low-protein binding 0.2 to 5 micron in-line or add-on filter.
- Know that the diluted solution can be infused via a central line or peripheral catheter. The drug should never be administered as an

intravenous bolus or push.

- Monitor patient for adverse reactions, especially infusion reactions that may include dizziness, dyspnea, fatigue, fever, hypertension, and nausea. Know that these reactions usually resolve within 24 hours.

**WARNING** Monitor patient closely for signs and symptoms of congestive heart failure, especially in patients with a history of the disorder. Notify prescriber immediately if such signs or symptoms are present and expect to provide supportive care.

## PATIENT TEACHING

- Remind patient that bezlotoxumab does not take the place of the prescribed antibacterial therapy. Reinforce need to continue taking the antibacterial agent as prescribed.
- Reassure patient that although infusion reactions may occur, they usually resolve within 24 hours and are not usually serious.

**WARNING** Urge patient to seek immediate medical attention if signs and symptoms of congestive heart failure occur.

# bisoprolol fumarate

## Class and Category

*Pharmacologic class:* Beta<sub>1</sub>-adrenergic blocker

*Therapeutic class:* Antihypertensive

## Indications and Dosages

- *To treat hypertension, alone or with other antihypertensives*

## **TABLETS**

**Adults.** 2.5 to 5 mg daily, increased to 10 to 20 mg daily if blood pressure doesn't respond to lower dosage.

***DOSAGE ADJUSTMENT*** Dosage reduced to 2.5 mg daily initially and then increased gradually for patients with impaired renal function and creatinine clearance less than 40 ml/min; who have impaired hepatic function, as from cirrhosis or hepatitis; or patients who have bronchospastic disease.

## **Mechanism of Action**

Inhibits stimulation of  $\beta_1$ -receptors primarily in the heart, which decreases cardiac excitability, cardiac output, and myocardial oxygen demand. Bisoprolol also decreases renin release from kidneys, which helps reduce blood pressure.

## **Contraindications**

Cardiogenic shock, hypersensitivity to bisoprolol or its components, overt heart failure, second- or third-degree heart block, sinus bradycardia

## **Interactions**

### **DRUGS**

*antiarrhythmics such as disopyramide; calcium channel blockers such as diltiazem, verapamil:* Increased risk of conduction delay and decreased heart rate

*beta blockers, digoxin:* Increased risk of bradycardia  
*catecholamine-depleting drugs such as guanethidine,*  
*reserpine:* Increased risk of bradycardia or hypotension  
*clonidine:* Possibly severe hypertension from withdrawal of  
clonidine or both drugs  
*rifampin:* Possibly increased bisoprolol metabolism with  
decreased bisoprolol effects

## Adverse Reactions

**CNS:** Anxiety, confusion, depression, dizziness, emotional lability, fatigue, fever, hallucinations, headache, insomnia, malaise, nightmares, paresthesia, sleep disturbances, syncope, tremor, unsteadiness, vertigo

**CV:** **Bradycardia, heart block, and other arrhythmias;** chest pain; claudication; cold arms and legs; edema; **heart failure;** hyper-cholesterolemia; hyperlipidemia; **hypotension; MI;** orthostatic hypotension; palpitations; peripheral vascular insufficiency

**EENT:** Altered taste, blurred vision, dry mouth, eye pain or pressure, hearing loss, increased salivation, laryngospasm, pharyngitis, rhinitis, sinusitis, tinnitus

**GI:** Constipation, diarrhea, epigastric pain, gastritis, indigestion, **ischemic colitis, mesenteric artery thrombosis,** nausea, vomiting

**GU:** Cystitis, decreased libido, impotence, Peyronie's disease, **renal artery thrombosis,** renal colic

**HEME:** **Agranulocytosis,** eosinophilia, **leukopenia, thrombocytopenia, thrombocytopenic purpura**

**MS:** Arthralgia, gout, muscle twitching, neck pain

**RESP:** **Asthma,** bronchitis, **bronchospasm,** cough, dyspnea, **respiratory distress,** upper respiratory tract

infection

**SKIN:** Alopecia, dermatitis, diaphoresis, eczema, **exfoliative dermatitis**, flushing, pruritus, psoriasis, rash

**Other:** **Angioedema**, **hyperkalemia**, hyperuricemia, weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Administer bisoprolol cautiously in patients with peripheral vascular disease because reduced cardiac output can cause or worsen arterial insufficiency. Assess patient's arms and legs for changes in color, temperature, and pulses; ask about numbness, tingling, and pain.
- Be aware that chronic beta blocker therapy, such as bisoprolol, is not routinely withheld prior to major surgery because the benefits outweigh the risks associated with its use with general anesthesia and surgical procedures.
- Measure blood pressure with patient lying, sitting, and standing before starting bisoprolol and then every 4 to 8 hours, as appropriate, to evaluate effectiveness.
- Know that if patient has diabetes, patient should be monitored closely for signs of hypoglycemia, which drug may mask.

- Be aware that if patient has hyperthyroidism, she should be watched for tachycardia and hypertension, which may be masked by bisoprolol.

**WARNING** Keep in mind that abrupt withdrawal of bisoprolol may cause or worsen thyroid storm. During drug withdrawal, monitor patient closely.

- Expect to stop bisoprolol over 1 to 2 weeks to prevent MI, ventricular arrhythmias, and, possibly, death from catecholamine hypersensitivity caused by beta blocker therapy.
- Monitor patient's blood pressure. If systolic blood pressure falls to less than 90 mm Hg, expect to discontinue drug. Prepare for hemodynamic monitoring, if needed.

**WARNING** Expect to discontinue bisoprolol about 48 hours beforehand if patient is scheduled for surgery with general anesthesia to reduce risk of excessive myocardial depression during anesthesia.

## PATIENT TEACHING

- Teach patient how to monitor her blood pressure, if appropriate, and to recognize signs of hypertension and hypotension.
- Instruct patient to avoid sudden position changes and to rise slowly from a lying or sitting position to minimize the effects of orthostatic hypotension.
- Advise patient to avoid driving and other activities that require mental alertness until bisoprolol's CNS effects are known.
- Instruct patient to contact prescriber before using any OTC product, such as a cold remedy or nasal decongestant.

# bivalirudin

## Angiomax

## Class and Category

*Pharmacologic class:* Direct thrombin inhibitor

*Therapeutic class:* Anticoagulant

## Indications and Dosages

- *As adjunct to provide anticoagulation and prevent thrombosis in patients with unstable angina who are having percutaneous transluminal coronary angioplasty; to provide anticoagulation in patients undergoing percutaneous coronary intervention (PCI); to treat patients with or at risk of heparin-induced thrombocytopenia (HIT) or heparin-induced thrombocytopenia and thrombosis syndrome (HITS) undergoing PCI*

### I.V. INFUSION

**Adults.** *Initial:* Immediately before procedure, 0.75-mg/kg bolus; then 1.75 mg/kg/hr as continuous infusion for duration of procedure. Five minutes after bolus dose and with continuous infusion running, another 0.3-mg/kg dose may be given, if needed, and patient does not have HIT, HITS, or STEMI. After procedure, 1.75 mg/kg/hr given for up to 4 hr by continuous infusion, followed by 0.2 mg/kg/hr for up to 20 hr, if needed.

**DOSAGE ADJUSTMENT** Infusion dosage possibly reduced to 1 mg/kg/hr for patients with severe renal impairment (glomerular filtration rate less than 30 ml/min) and to 0.25 mg/kg/hr for patients having hemodialysis.

Route	Onset	Peak	Duration
I.V.	Immediate	Unknown	1 hr after end of infusion

# Mechanism of Action

Selectively binds to thrombin, including thrombin trapped in established clots. Without thrombin, fibrinogen can't convert to fibrin and clots can't form.

# Incompatibilities

Don't mix other drugs in same I.V. line before or during bivalirudin administration. Mixing with alteplase, amiodarone, amphotericin B, chlorpromazine HCl, diazepam, prochlorperazine edisylate, reteplase, streptokinase, or vancomycin HCl can result in haze, particulate formation, or precipitation.

# Contraindications

Active major bleeding, hypersensitivity to bivalirudin or its components

# Interactions

## DRUGS

*glycoprotein IIb/IIIa inhibitors, heparin, thrombolytics, warfarin:* Risk of bleeding

# Adverse Reactions

**CNS:** Headache, **intracranial hemorrhage**

**CV:** **Acute stent thrombosis (patients with ST segment elevation myocardial infarction), cardiac tamponade, hypotension, thrombosis during PCI**

**EENT:** Epistaxis, gingival bleeding

**GI:** Abdominal cramps, diarrhea, GI or **retroperitoneal bleeding**, nausea, vomiting

**GU:** Hematuria, vaginal bleeding

**HEME:** **Absence of anticoagulant effect**, decreased hemoglobin, **increased INR**, **severe bleeding**

**MS:** Back pain

**RESP:** Hemoptysis, **hemothorax**, **pulmonary hemorrhage**

**SKIN:** Ecchymosis

**Other:** **Anaphylaxis**, antibody formation to bivalirudin, injection-site bleeding, hematoma, or pain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware drug should be given with aspirin.
- Reconstitute bivalirudin by adding 5 ml sterile water for injection to 250-mg vial and swirl gently until dissolved. For initial infusion, dilute reconstituted vial in 50 ml D<sub>5</sub>W or normal saline solution to yield 5 mg/ml.

- Know that for subsequent low-rate infusion, further dilute reconstituted drug in 500 ml D<sub>5</sub>W or normal saline solution to final concentration of 0.5 mg/ml.
- Expect to give 300 to 325 mg of aspirin P.O. daily during bivalirudin therapy.

**WARNING** Monitor blood coagulation tests before and regularly during therapy; bleeding is a major bivalirudin risk. Be aware that drug affects International Normalized Ratio (INR), so INR may not be useful for determining an appropriate warfarin dose.

**WARNING** Monitor patient often for bleeding because there's no antidote for bivalirudin. All patients with unexplained drop in blood pressure or hematocrit should be evaluated for bleeding. If life-threatening bleeding occurs, notify prescriber immediately, stop drug, and monitor APTT and other coagulation tests as ordered. Blood transfusions may be needed. Patients with increased bleeding risk include menstruating women; patients with large vessel or lumbar puncture, major surgery (including brain, eye, or spinal cord), major bleeding (including GI, intracranial, intraocular, pulmonary bleeding, or retroperitoneal), organ biopsy, recent stroke, or spinal anesthesia; and patients with organ or vascular abnormalities, such as advanced renal disease, dissecting aortic aneurysm, diverticulitis, hemophilia, hepatic disease (especially from deficient vitamin K-dependent clotting factors), infective endocarditis, inflammatory bowel disease, peptic ulcer disease, or severe uncontrolled hypertension. These patients should be monitored more frequently for bleeding.

- Know that if patient is receiving gamma brachytherapy, watch closely for evidence of thrombosis (weak or absent pulse, pallor, pain); use of bivalirudin may increase the risk in these patients.

- Avoid I.M. injections of any kind, if possible, to decrease the risk of bleeding.
- Discard any unused portion of drug.

## PATIENT TEACHING

- Inform patient that bivalirudin is a blood thinner administered only in the hospital.
- Urge patient to check her skin for bruising or red spots and to immediately report back for stomach pain, dizziness, fainting, trouble breathing, and unusual bleeding (black, tarry stool; blood in urine; coughing blood; heavy menses; nosebleeds). Drug may need to be stopped.
- Encourage patient to reduce the risk of injury while receiving bivalirudin, such as by brushing her teeth gently with a soft-bristled toothbrush.
- Caution patient not to take anti-inflammatories, such as aspirin or aspirin-like products, ibuprofen, ketoprofen, and naproxen, or other blood thinners, such as warfarin, while receiving bivalirudin unless directed.

# brexpiprazole

## Rexulti

## Class and Category

*Pharmacologic class:* Atypical antipsychotic

*Therapeutic class:* Antipsychotic

## Indications and Dosages

- *Adjunct treatment of major depressive disorder*

## TABLETS

**Adults.** *Initial:* 0.5 or 1 mg once daily, then increased to 1 or 2 mg once daily after 1 wk. Further increases in 1 mg increments made weekly, as needed. *Maximum:* 3 mg once daily.

➤ *To treat schizophrenia*

## TABLETS

**Adults.** *Initial:* 1 mg once daily for 4 days, followed by 2 mg once daily for 3 days, then increased to 4 mg once daily. *Maximum:* 4 mg once daily.

**DOSAGE ADJUSTMENT** For patients with moderate to severe hepatic impairment or moderate to severe or end-stage renal impairment (creatinine clearance less than 60 ml/min), maximum dosage should not exceed 2 mg once daily for patients with major depressive disorder and 3 mg for patients with schizophrenia. For patient who is a CYP2D6 poor metabolizer or patient is taking strong CYP2D6 or CYP3A4 inhibitors, dosage reduced by 50%. For patient who is a CYP2D6 poor metabolizer who is also taking moderate to strong CYP3A4 inhibitors or patient taking both a moderate to strong CYP2D6 inhibitor and a moderate to strong CYP3A4 inhibitor, dosage reduced by 75%. For patient taking strong CYP3A4 inducers, dosage doubled over 1 to 2 wk.

## Mechanism of Action

May produce antipsychotic effects through partial agonist and antagonist actions. Brexpiprazole acts as a partial agonist at dopamine (especially D<sub>2</sub>) receptors and serotonin (especially 5-HT<sub>1a</sub>) receptors. The drug acts as an antagonist at 5-HT<sub>2a</sub> serotonin receptor sites.

# Contraindications

Hypersensitivity to brexpiprazole or its components

# Interactions

## DRUGS

*clarithromycin, itraconazole, ketoconazole, and other strong CYP3A4 inhibitors; combination of a strong CYP3A4 inhibitor/strong CYP2D6 inhibitor (itraconazole/quindine), moderate CYP3A4 inhibitor/strong CYP2D6 inhibitor (fluconazole/paroxetine), strong CYP3A4 inhibitor/moderate CYP2D6 inhibitor (itraconazole/duloxetine), moderate CYP3A4 inhibitor/moderate CYP2D6 inhibitor (fluconazole/duloxetine); fluoxetine, paroxetine, quinidine, and other strong CYP2D6 inhibitors:* Increased brexpiprazole exposure and possibly increased adverse brexpiprazole-related reactions  
*rifampin, St. John's wort, and other strong CYP3A4 inducers:* Decreased brexpiprazole exposure and effectiveness

# Adverse Reactions

**CNS:** Abnormal dreams, akathisia, anxiety, body temperature dysregulation, **CVA**, dizziness, dyskinesia, dystonia, fatigue, headache, impaired cognitive and motor skills, insomnia, restlessness, **seizures**, somnolence, **suicidal ideation**, syncope, tardive dyskinesia, tremor

**CV:** Dyslipidemia, orthostatic hypotension

**EENT:** Blurred vision, dry mouth, excessive salivation, nasopharyngitis

**ENDO:** Decreased blood cortisol levels, hyperglycemia

**GI:** Abdominal pain, constipation, diarrhea, dyspepsia, flatulence, increased appetite, nausea

**GU:** UTI

**HEME:** Agranulocytosis, leukopenia, neutropenia

**MS:** Myalgia

**SKIN:** Hyperhidrosis

**Other:** Increased blood creatine phosphokinase level, pathological gambling and other compulsive behaviors, weight gain

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-961-2388 or <http://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/>.
- It is not known if drug can cause fetal harm. However, extrapyramidal and/or withdrawal symptoms have been reported in neonates whose mothers were exposed to antipsychotic drugs during the third trimester of pregnancy.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that brexpiprazole shouldn't be used to treat dementia-related psychosis in the elderly because of an increased risk of death.
- Use brexpiprazole cautiously in patients with a history of seizures or with conditions that lower the seizure threshold. Also use cautiously in patients at risk for aspiration pneumonia because esophageal dysphagia has been associated with antipsychotic drug use.
- Monitor patient's CBC, as ordered, because serious adverse hematologic reactions, such as agranulocytosis, leukopenia, and neutropenia may occur with atypical antipsychotic therapy. Assess more often during first few months of therapy if patient has a history of drug-induced leukopenia or neutropenia or a significantly low WBC count. If abnormalities occur during therapy, watch for fever or other signs of infection, notify prescriber and, if severe, expect drug to be stopped.
- Monitor patient for tardive dyskinesia, especially in elderly women. Know that it has the potential to be irreversible and the risk for developing tardive dyskinesia increases the longer brexpiprazole is used and the higher the total cumulative dose. If it occurs, notify prescriber and expect drug to be discontinued, if possible.
- Monitor patient's blood glucose level, lipid levels, and weight, as ordered, because atypical antipsychotic drugs such as brexpiprazole may cause metabolic changes. If patient is already a diabetic, monitor blood glucose levels more closely.

**WARNING** Know that antipsychotic drugs may cause neuroleptic malignant syndrome. Monitor patient closely throughout brexpiprazole therapy. If suspected, notify prescriber immediately, be prepared to provide emergency supportive care, and expect drug to be discontinued.

- Watch patients closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times.

## PATIENT TEACHING

- Advise patient to get up slowly from a lying or sitting position during brexpiprazole therapy to minimize a drop in blood pressure.

- Instruct patient to avoid hazardous activities until drug's effects are known. Also, alert patient and family of increased risk for falls, especially if patient has other medical conditions or takes medication that may affect the nervous system.
- Urge patient to avoid activities that raise body temperature suddenly, such as strenuous exercise and exposure to extreme heat, and to compensate for situations that cause dehydration, such as vomiting or diarrhea.
- Instruct patient to inform all prescribers of any drugs he's taking, including OTC drugs, because of risk of interactions.
- Advise female patient of childbearing age to notify prescriber if she intends to become or suspects that she is pregnant during therapy.
- Instruct diabetic patient to monitor blood glucose levels closely.
- Tell family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Inform patient and family or caregiver that drug may cause intense urges, particularly for gambling, but may also cause sexual urges, uncontrollable shopping, binge eating, and other impulsive or compulsive behaviors. These behaviors may not be recognized as abnormal by patient. Urge the reporting of such behaviors as a dosage reduction or discontinuation of the drug may be required to protect patient from these harmful effects.

**brivaracetam**

**Briviact**

## **Class, Category, Schedule**

*Pharmacologic class:* Anticonvulsant

*Therapeutic class:* Anticonvulsant

*Controlled substance schedule:* V

# Indications and Dosages

➤ *To treat partial-onset seizures in patients with epilepsy*

## ORAL SOLUTION, TABLETS

**Adults and adolescents age 16 and over.** *Initial:* 50 mg twice daily followed by dosage reduction to 25 mg twice daily or dosage increase to 100 mg twice daily depending on therapeutic response and patient tolerance.

**Children age 4 to 16 weighing 50 kg (110 lb) or more.** *Initial:* 25 to 50 mg twice daily followed by dosage adjustment depending on patient tolerance and therapeutic response. Dosage maybe be reduced to 25 mg twice daily if dose started at 50 mg twice daily or dosage increased to 100 mg twice daily, if needed.

**Children age 4 to 16 weighing 20 kg (44 lb) to less than 50 kg (110 lb).** *Initial:* 0.5 mg/kg to 1 mg/kg twice daily followed by dosage increase up to 2 mg/kg twice daily depending on therapeutic response and patient tolerance.

**Children age 4 to 16 weighing 11 kg (24.2 lb) to less than 20 kg (44 lb).** *Initial:* 0.5 mg/kg to 1.25 mg/kg twice daily followed by dosage increase up to 2.5 mg/kg twice daily depending on therapeutic response and patient tolerance.

## I.V. INJECTION

**Adults and adolescents age 16 and over.** *Initial:* 50 mg injected over 2 to 15 min twice daily followed by dosage reduction to 25 mg twice daily or dosage increase to 100 mg twice daily depending on therapeutic response and patient tolerance.

***DOSAGE ADJUSTMENT*** For adult patient and pediatric patient weighing 50 kg (110 lb) or more with hepatic impairment

of any severity, initial dosage reduced to 25 mg twice daily, with maximum dosage not to exceed 75 mg twice daily. For pediatric patient with hepatic impairment weighing 11 kg (24.2 lb) to less than 50 kg (110 lb), initial dosage not to exceed 0.5 mg/kg twice daily. For pediatric patient with hepatic impairment weighing 20 kg (44 lb) to less than 50 kg (110 lb), maximum dosage not to exceed 1.5 mg/kg twice daily and for pediatric patient with hepatic impairment weighing 11 kg (24.2 lb) to less than 20 kg (44 lb), maximum dosage not to exceed 2 mg/kg twice daily. For patient receiving rifampin concurrently, dosage of brivaracetam doubled.

Route	Onset	Peak	Duration
P.O., I.V.	1 hr	Unknown	Unknown

## Mechanism of Action

Displays a high and selective affinity for synaptic vesicle protein 2A (SV2A) in the brain, which may contribute to the anticonvulsant effect, although the exact mechanism is unknown.

## Incompatibilities

Do not mix with solutions other than 0.9% sodium chloride injection USP; 5% Dextrose Injection, USP; or Lactated Ringer's injection and do not administer with other drugs in same intravenous line because incompatibilities are unknown.

## Contraindications

Hypersensitivity to brivaracetam or its components

# Interactions

## DRUGS

*carbamazepine*: Possibly increased exposure of carbamazepine that may lead to adverse reactions

*phenytoin*: Increased plasma concentrations of phenytoin that may lead to adverse reactions

*rifampin*: Decreased plasma concentrations of brivaracetam significantly interfering with its effectiveness and requiring a dosage increase to compensate

## Adverse Reactions

**CNS:** Abnormal behavior, acute psychosis, adjustment disorder, affect lability, aggression, agitation, altered mood, anger, anxiety, apathy, balance and cerebellar coordination disturbances, belligerence, depression, dizziness, euphoria (parenteral form), fatigue, feeling drunk (parenteral form), hallucinations, irritability, mood swings, nervousness, paranoia, psychomotor hyperactivity, psychotic behavior or disorder, restlessness, sedation, somnolence, **suicidal ideation**

**EENT:** Taste disturbance (parenteral form)

**GI:** Constipation, nausea, vomiting

**HEME:** **Leukopenia**, **neutropenia**

**RESP:** **Bronchospasm**

**Other:** **Angioedema**, infusion-site pain

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.
- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that brivaracetam oral solution may be administered via a gastrostomy or nasogastric tube.
- Administer parenteral form of brivaracetam only as an intravenous injection. It may be given without further dilution or it may be mixed with any of the following solutions: 0.9% sodium chloride injection, USP, 5% Dextrose Injection, USP, or Lactated Ringer's injection. Administer over 2 to 15 minutes. If diluted, the solution should not be stored for more than 4 hours at room temperature and may be stored in polyvinyl chloride bags. Discard any unused portion of the parenteral solution remaining in the vial.
- Know that oral dosage and parenteral dosage are interchangeable. However, be aware that the parenteral form should not be used in children under the age of 16 because safety has not been established.

**WARNING** Monitor patient closely for abnormal behavior or thoughts, because brivaracetam may increase risk of suicidal thoughts or behavior.

**WARNING** Monitor patient for hypersensitivity reactions, especially angioedema and bronchospasm. If present, notify prescriber, expect brivaracetam to be discontinued, and be prepared to provide supportive care.

- Take safety measures to prevent patient from falling, because brivaracetam may cause dizziness and disturbances in coordination and gait.
- Know that brivaracetam may cause psychiatric adverse reactions. Notify prescriber, if present, and take measures to keep patient calm and safe.
- Be aware that brivaracetam should not be discontinued abruptly, because of increased risk of seizure frequency and the potential for status epilepticus.

## PATIENT TEACHING

- Inform patient prescribed tablet form to swallow tablets whole with a beverage. Tell patient tablets should not be chewed or crushed.
- Inform patient prescribed oral solution form to use a calibrated measuring device to measure and deliver the prescribed dose. Remind patient that a household tablespoon or teaspoon is not an adequate measuring device. Tell patient the oral solution need not be diluted. Have patient discard any unused oral solution after 5 months of first opening the bottle.

**WARNING** Have family or caregiver monitor patient closely for abnormal behavior or thoughts, because drug may increase risk of suicidal thoughts and behavior.

- Advise patient to avoid performing hazardous activities such as driving or operating machinery until central nervous system effects of brivaracetam are known and have abated.
- Remind patient to be careful and use safety precautions when walking or performing physical activities because brivaracetam may cause disturbances in coordination and gait and dizziness.
- Advise patient and family or caregiver that brivaracetam may cause changes in behavior such as aggression, agitation, anger, anxiety, and irritability along with psychotic symptoms. Instruct patient or family/caregiver to report these changes immediately to the prescriber.
- Tell women of childbearing age to notify prescriber if pregnancy is suspected or known. If confirmed, encourage patient to enroll in the pregnancy exposure registry by calling 1-888-233-2334.

# brodalumab

**Siliq**

## Class and Category

*Pharmacologic class:* Monoclonal IgG2 antibody

*Therapeutic class:* Antipsoriatic

## Indications and Dosages

- *To treat moderate to severe plaque psoriasis in patients who are candidates for systemic therapy or phototherapy and have failed to respond or have lost response to other systemic therapies*

## SUBCUTANEOUS INJECTION

**Adults.** *Initial:* 210 mg followed by 210 mg repeated at day 7 and 14, and then 210 mg every 2 wk.

## Mechanism of Action

Binds to human IL-17RA and inhibits its interactions with selective cytokines. This inhibits the release of proinflammatory chemokines and cytokines, which are thought to be part of the pathogenesis of plaque psoriasis.

## Contraindications

Crohn's disease, hypersensitivity to brodalumab or its components

# Interactions

## DRUGS

*CYP450 substrates such as cyclosporine or warfarin:*

Possibly altered effectiveness of these drugs

*live vaccines:* Failure to produce an adequate immune response

## Adverse Reactions

**CNS:** Headache, fatigue, **suicidal ideation**

**EENT:** Nasopharyngitis, oropharyngeal pain, pharyngitis

**GI:** Crohn's disease, diarrhea, nausea

**GU:** UTI

**HEME:** **Neutropenia**

**MS:** Arthralgia, myalgia

**RESP:** Bronchitis, upper respiratory infections

**SKIN:** Tinea infections, urticaria

**Other:** Antibrodalumab antibody formation, flu-like symptoms, injection-site reactions (bruising, erythema, hemorrhage, pain, pruritus)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm. However, human IgG antibodies are known to cross the placental barrier; therefore, drug may be transmitted from the mother to the fetus.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Expect patient to be evaluated for tuberculosis before brodalumab therapy is begun. If present, know that brodalumab should not be initiated until treatment for latent tuberculosis has been given. Monitor all patients for signs and symptoms of tuberculosis during and after brodalumab therapy.
- Use cautiously in patients with a chronic infection or who have a history of recurrent infections, because brodalumab increases the risk of infections, especially fungal infections. If an infection occurs and does not respond to standard therapy for the infection, expect brodalumab to be withheld until the infection is resolved.

**WARNING** Know that brodalumab is only available through a restricted program because of its potential to cause suicidal behavior and thoughts. Monitor patient closely and expect drug to be discontinued if suicidal ideation is present.

- Allow prefilled syringe to reach room temperature before administering, which is about 30 minutes. Administer only as a subcutaneous injection. Do not inject into an area that is affected by psoriasis or is bruised, hard, red, scaly, tender, or thick. Know that the solution in the pen should appear clear to slightly opalescent, colorless to slightly yellow, and may have a few translucent to white particles. Do not use if cloudy or discolored or if foreign matter is present. Inject the full amount in the syringe to provide the correct dosage.
- Monitor patient for Crohn's disease and know that brodalumab must be discontinued if patient develops this disease while taking the drug.
- Avoid administering live vaccines while patient is receiving brodalumab because vaccines may not be effective.

## PATIENT TEACHING

- Instruct patient self-administering brodalumab how to properly administer a subcutaneous injection. Tell patient not to inject the drug in an area that is affected by psoriasis or is bruised, hard, scaly, tender, or thick.
- Tell patient to allow the prefilled syringe to reach room temperature (which takes about 30 minutes) before injecting the drug. Remind patient not to remove the gray needle cap on the syringe while allowing it to reach room temperature. Prior to injection, tell patient to look at solution inside the syringe. It should be clear to slightly opalescent, colorless to slightly yellow. A few translucent to white particles may be present. If solution appears cloudy or discolored or if foreign matter is present, the syringe should be discarded and a replacement obtained. Tell patient to inject the full amount of solution contained in the prefilled syringe. Advise patient to rotate sites.
- Advise patient to seek medical attention if signs or symptoms of infection occur.
- Tell patient to notify prescriber if persistent or severe bowel problems develop. If Crohn's disease is diagnosed, inform patient that brodalumab therapy must be discontinued.

**WARNING** Alert patient or family that drug may produce suicidal behavior or thoughts. If present, suicide precautions should be undertaken, prescriber notified, and drug discontinued.

## bromocriptine mesylate

**Alti-Bromocriptine (CAN), Apo-Bromocriptine (CAN), Cycloset, Parlodel, Parlodel SnapTabs**

### Class and Category

*Pharmacologic class:* Dopamine receptor agonist

*Therapeutic class:* Antidiabetic, antidyskinetic, antihyperprolactinemic, dopamine-receptor agonist, growth hormone suppressant, infertility therapy adjunct

## Indications and Dosages

- *To treat amenorrhea, galactorrhea, male hypogonadism, and infertility from hyperprolactinemia*

### CAPSULES, TABLETS (PARLODEL)

**Adults and adolescents age 15 and over.** *Initial:* 1.25 to 2.5 mg daily with snack. Increased by 2.5 mg every 2 to 7 days as needed. *Maintenance:* 2.5 to 15 mg daily.

**Children ages 11 to 15 years with a prolactin-secreting pituitary adenoma.** 1.25 to 2.5 mg daily with snack. Increased as needed and tolerated. *Maintenance:* 2.5 to 10 mg daily.

- *To treat Parkinson's disease*

### CAPSULES, TABLETS (PARLODEL)

**Adults.** *Initial:* 1.25 mg twice daily with meals. Increased by 2.5 mg every 14 to 28 days, as needed. *Maximum:* 100 mg daily.

- *To treat acromegaly*

### CAPSULES, TABLETS (PARLODEL)

**Adults and children age 15 and over.**

*Initial:* 1.25 to 2.5 mg at bedtime with snack for 3 days. Then increased by 1.25 to 2.5 mg every 3 to 7 days, if needed. *Maintenance:* Usually 20 to 30 mg daily. *Maximum:* 100 mg daily.

- *To control blood glucose level in type 2 diabetes mellitus, with diet and exercise*

## TABLETS (CYCLOSET)

**Adults.** *Initial:* 0.8 mg once daily within 2 hr after waking up in morning. Increased weekly in increments of 0.8 mg, as needed. *Maximum:* 4.8 mg daily.

***DOSAGE ADJUSTMENT*** For patients taking Cycloset and a moderate CYP3A4 inhibitor such as erythromycin, dosage not to exceed beyond 1.6 mg once daily.

Route	Onset	Peak	Duration
P.O.*	2 hr	8 hr	24 hr
P.O.†	30-90 min	2 hr	Unknown
P.O.‡	1-2 hr	4-8 wk	4-8 hr

\* For amenorrhea, galactorrhea, male hypogonadism, infertility from hyperprolactinemia, and prolactin-secreting adenoma.

† For Parkinson's disease.

‡ For acromegaly.

## Mechanism of Action

Inhibits release of growth and prolactin hormones from the anterior pituitary gland, thus restoring ovarian or testicular function and suppressing lactation. Bromocriptine decreases dopamine turnover in the CNS, depleting dopamine or blocking its receptors in the brain, alleviating dyskinesia.

## Contraindications

Breastfeeding; hypersensitivity to bromocriptine, other ergot alkaloids, or their components; pregnancy including

hypertensive disorders of pregnancy (unless absolutely medically necessary); postpartum period in women with history of coronary artery disease and other severe cardiovascular conditions (unless absolutely medically necessary); syncopal migraine (Cycloset); uncontrolled hypertension

## Interactions

### DRUGS

*antihypertensives*: Increased hypotensive effects

*CYP3A4 inducers*: Decreased bromocriptine level

*CYP3A4 inhibitors*: Increased bromocriptine level

*dopamine receptor antagonists, including neuroleptic drugs (such as butyrophenones, phenothiazines, or thioxanthenes), metoclopramide*: Possibly decreased effectiveness of both drugs

*ergot alkaloids or derivatives*: Increased risk of hypertension

*highly protein bound drugs such as chloramphenicol, probenecid, salicylates, sulfonamides*: Possibly altered effectiveness of these drugs and increased risk of adverse reactions

*levodopa*: Additive effects requiring reduced levodopa dose

*macrolide antibiotics such as erythromycin*: Increased plasma bromocriptine levels

*oral contraceptives*: Possibly decreased effectiveness of oral contraceptives

*sympathomimetic drugs*: Possibly increased risk of hypertension and tachycardia

### ACTIVITIES

*alcohol use*: Possibly increased risk of adverse effects of bromocriptine

# Adverse Reactions

**CNS:** Asthenia, confusion, dizziness, drowsiness, fatigue, hallucinations, headache, light-headedness, syncope

**CV:** Hypertension, **hypotension**, orthostatic hypotension, pericardial effusion, pericarditis, Raynaud's phenomenon

**EENT:** Amblyopia, dry mouth, nasal congestion, rhinitis, sinusitis

**ENDO:** **Hypoglycemia**

**GI:** Abdominal cramps, anorexia, constipation, diarrhea, **GI bleeding**, indigestion, nausea, vomiting

**RESP:** Pleural effusion or thickening, **pulmonary fibrosis**

**Other:** Intense urge to gamble, engage in sexual activity, or spend money uncontrollably

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug normally should not be used during pregnancy and should be discontinued when pregnancy occurs due to risk to mother. However, if drug is medically necessary, it may be given but only if benefit to mother outweighs the possible risk associated with a potential hypertensive disorder of pregnancy.

## LACTATION

- Drug is contraindicated for use in mothers who are breastfeeding.

## REPRODUCTION

- Pregnancy should be avoided by using effective contraception other than oral contraceptives during drug therapy.
- Drug is not recommended for use in the postpartum period in women with a history of coronary artery disease and other severe cardiovascular conditions unless no other alternative is available and withdrawal of drug is medically contraindicated.
- Patient should be made aware that after menses resumes after delivery; she should be tested for pregnancy every 4 weeks or as soon as menstruation is missed during drug therapy.

## Nursing Considerations

- Use bromocriptine cautiously if patient has a history of psychosis or cardiovascular disease, especially after MI with residual arrhythmia. In severe psychotic disorder, bromocriptine isn't recommended because it may worsen the disorder or reduce the effects of drugs used to treat it.
- Use bromocriptine cautiously in patients with Parkinson's disease because high doses of the drug may cause confusion and mental disturbances in these patients. Drug should not be discontinued abruptly, as a symptom complex resembling the neuroleptic malignant syndrome has occurred with rapid dose reduction, withdrawal, or changes in antiparkinsonian therapy.
- Expect to perform a pregnancy test every 4 weeks during the amenorrheic period. Once menses resume, test whenever a period is missed, as ordered.
- Plan to withhold bromocriptine if patient becomes pregnant.
- Know that if rapidly expanding adenoma needs continued therapy, watch closely for hypertensive crisis.
- Be aware that bromocriptine shouldn't be given postpartum if patient has a history of coronary artery disease or other severe cardiovascular problem unless risk of withdrawing drug is greater than risk of use. If so, monitor closely for signs and symptoms of CV dysfunction, such as chest pain.
- Expect to give drug with levodopa if patient is being treated for Parkinson's disease.
- Assess for hypotension when bromocriptine therapy starts and hypertension (typically during second week). Monitor blood pressure often if patient takes other antihypertensives.

- Assess patient who has a history of peptic ulcer or GI bleeding for new bleeding.
- Take safety precautions, such as keeping bed in low position with side rails up, because drug can cause dizziness, drowsiness, light-headedness, and syncope.

## **PATIENT TEACHING**

- Tell patient to take each dose with a meal, milk, or a snack to minimize nausea.
- Caution patient about possible dizziness, drowsiness, and light-headedness. Urge patient to avoid hazardous activities until drug effects are known.
- Advise against sudden position changes to minimize orthostatic hypotension.
- Warn patient to avoid alcohol while taking bromocriptine because it may cause disulfiram-like reactions, such as blurred vision, chest pain, confusion, diaphoresis, a fast or pounding heartbeat, facial flushing, nausea, severe weakness, throbbing headache, or vomiting.
- Tell patient to take a missed dose as soon as she remembers it, unless it's almost time for the next dose. In that case, tell her to wait until the next scheduled dose. Warn her not to double the dose. Advise her to contact prescriber if she misses more than one dose.
- Urge patient to report adverse reactions, such as nausea, unremitting headache, vomiting, or other signs of CNS toxicity.
- Tell patient who takes large doses of bromocriptine to schedule regular dental checkups because the drug can decrease saliva flow, which may encourage dental caries, oral candidiasis, oral discomfort, or periodontal disease.
- Tell patient with acromegaly to keep her fingers warm to prevent cold-sensitive digital vasospasm.
- Teach patient with type 2 diabetes about diet, exercise, effects of hyperglycemia and hypoglycemia, hygiene, foot care, and ways to avoid infection.
- Warn patient to report intense urges to gamble, engage in sexual activity, or spend money uncontrollably.
- Stress importance of women of childbearing age to report known or suspected pregnancy immediately and not to breastfeed during drug

therapy.

## budesonide

**Entocort EC, Pulmicort Flexhaler,  
Pulmicort Respules, Rhinocort Aqua,  
Uceris**

### Class and Category

*Pharmacologic class:* Corticosteroid

*Therapeutic class:* Antiasthmatic, anti-inflammatory

### Indications and Dosages

- *To manage symptoms of seasonal or perennial allergic rhinitis*

#### **NASAL SPRAY (RHINOCORT AQUA)**

**Adults and children age 6 and over.** 32 mcg in each nostril daily.

*Maintenance:* Lowest dosage that controls symptoms.

*Maximum:* For adults and children age 12 and over: 256 mcg once daily administered as four sprays (32 mcg/spray) per nostril. For children age 6 to less than 12 years of age: 128 mcg once daily administered as two sprays (32 mcg/spray) per nostril.

- *To provide maintenance therapy in asthma*

#### **ORAL INHALATION (PULMICORT FLEXHALER)**

**Adults and adolescents age 18 and over.** *Initial:* 180 or 360 mcg twice daily, increased as needed. *Maximum:* 720 mcg twice daily.

**Children ages 6 to 17.** *Initial:* 180 or 360 mcg twice daily. *Maximum:* 360 mcg twice daily.

## **NEBULIZED INHALATION (PULMICORT RESPULES)**

**Children ages 1 to 8 previously on bronchodilators alone.** 0.25 mg twice daily. or 0.5 mg daily by jet nebulizer. *Maximum:* 0.5 mg/day.

**Children ages 1 to 8 previously on inhaled steroids.** 0.25 mg twice daily or 0.5 mg daily inhaled by jet nebulizer. *Maximum:* 1 mg/day.

**Children ages 1 to 8 previously on systemic corticosteroids.** 0.5 mg twice daily or 1 mg daily inhaled by jet nebulizer. *Maximum:* 1 mg/day.

- *To treat mild to moderate active Crohn's disease involving the ileum, the ascending colon, or both*

## **CAPSULES (ENTOCORT EC)**

**Adults.** 9 mg daily in the morning for **up to 8 wk.**

**Children age 8 to 17 weighing more than 25 kg (55 lb).** 9 mg once daily for 8 wk, followed by 6 mg once daily for 2 wk.

- *To maintain clinical remission of mild to moderate Crohn's disease involving the ileum, the ascending colon, or both*

## **CAPSULES (ENTOCORT EC)**

**Adults.** 6 mg daily in the morning for up to 3 mo.

***DOSAGE ADJUSTMENT*** *For Entocort EC:* For adult patients with moderate hepatic impairment, dosage reduced to 3 mg

once daily for duration of treatment.

- *To induce remission in patients with active, mild to moderate ulcerative colitis*

## **E.R. TABLETS (UCERIS)**

**Adults.** 9 mg daily in the morning for up to 8 wk.

***DOSAGE ADJUSTMENT*** *For Uceris:* Dosage may be reduced for patients with hepatic insufficiency and those taking ketoconazole or other CYP3A4 inhibitor.

- *To induce remission in patients with active, mild to moderate distal ulcerative colitis extending up to 40 cm from the anal verge*

## **RECTAL FOAM (UCERIS)**

**Adults.** 1 metered dose (2 mg) twice daily for 2 wk followed by 1 metered dose (2 mg) once daily for 4 wk.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
Nasal suspension	In 4 wk	Unknown	Unknown
Oral inhalation	In 4 wk	Unknown	Unknown
Nebulized inhalation	2-8 days	4-6 wk	Unknown
P.O. (capsules)	Unknown	30 min- 10 hr	Unknown
P.O. (ER tablets)	Unknown	13 hr	Unknown
Rectal foam	Unknown	Unknown	Unknown

## **Mechanism of Action**

Inhibits inflammatory cells and mediators, possibly by decreasing influx into nasal passages, bronchial walls, or the intestines. As a result, nasal or airway inflammation decreases. Oral inhalation form also inhibits mucus

secretion in airways, decreasing the amount and viscosity of sputum.

## Contraindications

Hypersensitivity to budesonide or its components, recent septal ulcers or nasal surgery or trauma (nasal spray); status asthmaticus or other acute asthma episodes (oral inhalation)

## Interactions

### DRUGS

*antacids, H2 blockers, proton pump inhibitors* (oral Uceris): Dissolution of the coating of oral Uceris may be altered

*clarithromycin, erythromycin, itraconazole, ketoconazole and other strong CYP3A4 inhibitors such as atazanavir, clarithromycin, indinavir, itraconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin*: Possibly increased blood budesonide level

### FOOD

*grapefruit juice*: Possibly increased blood budesonide level

## Adverse Reactions

**CNS:** Amnesia, asthenia, **benign intracranial hypertension**, changes in mood, dizziness, fatigue, fever, headache

**CV:** Hypertension, peripheral edema

**EENT:** Bad taste, cataracts, dry mouth, epistaxis, glaucoma, nasal irritation, oral or pharyngeal candidiasis,

pharyngitis, rhinitis, sinusitis

**ENDO:** **Adrenal insufficiency**, growth suppression in children, hypercorticism

**GI:** Abdominal pain, diarrhea, dyspepsia, flatulence, indigestion, nausea, **pancreatitis**, **rectal bleeding**, vomiting

**GU:** UTI

**MS:** Arthralgia, back pain, muscle cramps and spasms

**RESP:** **Bronchospasm**, increased cough, respiratory tract infection

**SKIN:** Allergic or contact dermatitis, maculo-papular rash, pruritus, purpura, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, increased risk of infection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm but it may cross the placental barrier.
- Hypoadrenalism in infants may occur when mothers have received substantial doses of corticosteroids during pregnancy, especially oral forms. Inhaled corticosteroids pose less risk.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk following inhalation of the drug. It is unknown if drug is present in breast milk following oral administration.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Use budesonide cautiously if patient has ocular herpes simplex; tubercular infection; or untreated fungal, bacterial, or systemic viral infection.
- Closely monitor a child's growth pattern; budesonide may stunt growth.

**WARNING** Assess patient who switches from a systemic corticosteroid to inhaled budesonide for adrenal insufficiency (fatigue, hypotension, lassitude, nausea, vomiting, weakness), which may be life-threatening. Hypothalamic-pituitary-adrenal axis function may take several months to recover after stopping systemic corticosteroids. Stopping budesonide abruptly may cause adrenal insufficiency.

- Administer Respules by jet nebulizer connected to an air compressor.
- Monitor patient exposed to chickenpox. Know that he may receive varicella zoster immune globulin or pooled I.V. immunoglobulin. If chickenpox develops, give antiviral as ordered. A patient exposed to measles may need pooled I.M. immunoglobulin.
- Assess patient for effectiveness of budesonide therapy, especially if being weaned from a systemic corticosteroid. If patient has increased asthma or an immunologic condition previously suppressed by systemic corticosteroid—such as arthritis, conjunctivitis, an eosinophilic condition, eczema, or rhinitis—notify prescriber.
- Determine if patient has a milk allergy. Pulmicort Flexhaler contains small amounts of lactose, which may trigger coughing, wheezing, or bronchospasm in a patient with a severe milk-protein allergy.
- Monitor patient for evidence of hypersensitivity. If present, notify prescriber immediately. Expect to stop budesonide and provide emergency supportive care.
- Monitor patients with conditions such as diabetes mellitus, glaucoma or cataracts, hypertension, osteoporosis, or peptic ulcer, as glucocorticosteroid therapy may increase adverse effects. Also monitor patients with a family history of diabetes or glaucoma.

# PATIENT TEACHING

- Urge patient taking oral capsules or E.R. tablets to swallow them whole and not to chew or break them. However for the patient who cannot swallow an intact capsule tell her to place one tablespoonful of applesauce into an empty bowl. Applesauce should not be hot and should be soft enough to swallow without chewing. Then patient should open capsule and carefully empty all the granules inside onto the applesauce. She should mix the granules with the applesauce and consume the entire contents within 30 minutes of mixing followed immediately by drinking an eight ounce glass of cool water. Stress importance of not chewing or crushing the granules nor should she save the applesauce and granules for future use.
- Instruct patient who uses nasal spray to shake container before each use. Instruct her to blow her nose, tilt her head slightly forward, and insert tube into a nostril, pointing toward inner corner of eye, away from nasal septum. Tell her to hold the other nostril closed and spray while inhaling gently. Then have her repeat in the other nostril.
- Instruct patient to prime oral inhaler before using it for first time by holding canister upright with mouthpiece on top and twisting base of device fully to right and then fully to left until it clicks. Teach her to load each dose just before use in the same way. After loading a dose, caution patient not to shake device or blow into it. Tell patient to turn her head away from device and exhale. Then have her hold device upright, place her lips around mouthpiece, and inhale deeply. Device will discharge a dose. Tell patient to remove her lips from mouthpiece to exhale.
- Instruct patient to empty her bowels before using rectal foam. Although product is lubricated, tell patient she may use petroleum jelly or petrolatum if more lubrication is needed. Tell her to warm the canister in her hands while shaking it vigorously for 10 to 15 seconds prior to use. Inform her that she may apply the rectal foam while standing, lying, or sitting. When applied in the evening, instruct her to do so immediately before bedtime and advise her to try not to empty her bowels again until morning. Warn patient to keep canister away from heat sources, as its contents are flammable.
- Caution patient not to use an oral inhaler with a spacer device.
- Advise patient to rinse her mouth with water after each orally inhaled dose and to spit the water out. Tell her to contact her prescriber if she develops a mouth or throat infection.
- Instruct patient not to use budesonide as a rescue inhaler.

- Tell patient to contact prescriber if symptoms persist or have worsened after 3 weeks. Caution against increasing the dose on her own.
- Inform parents of small children using nebulized Respules that improvement may begin within 2 to 8 days but that full effect may not be evident for 4 to 6 weeks.
- Caution patient to avoid exposure to chickenpox and measles and, if exposed, to contact prescriber immediately.
- Caution against stopping drug abruptly.
- Instruct patient on long-term therapy to have regular eye examinations.
- Urge female patient to notify prescriber if she is or could be pregnant.
- Strongly encourage mothers who wish to breastfeed an infant to discuss breastfeeding with prescriber before doing so.

## bumetanide

### Bumex

## Class and Category

*Pharmacologic class:* Loop diuretic as sulfonamide derivative

*Therapeutic class:* Diuretic

## Indications and Dosages

- *To treat edema caused by heart failure, hepatic disease, and renal disease, including nephrotic syndrome*

### **TABLETS**

**Adults.** 0.5 to 2 mg daily, increased as needed, with a second or third dose every 4 to 5 hr or 0.5 to 2 mg every other day or daily for 3 or 4 days each week. *Maximum:* 10 mg daily.

## **I.M. INJECTION, I.V. INFUSION, I.V. INJECTION**

**Adults.** 0.5 to 1 mg daily, increased as needed with a second or third dose every 2 to 3 hr. I.V. infusion given at 0.1 mg/hr to 1 mg/hr. I.V. injection given over 1 to 2 min. *Maximum:* 10 mg daily.

Route	Onset	Peak	Duration
P.O.	30-60 min	1-2 hr	4-6 hr
I.V.	In min	15-30 min	3.5-4 hr

## **Mechanism of Action**

Inhibits reabsorption of sodium, chloride, and water in the ascending limb of the loop of Henle, which promotes their excretion and reduces fluid volume.

## **Contraindications**

Anuria, hepatic coma, hypersensitivity to bumetanide or its components, marked increase in BUN or creatinine levels or development of oliguria if progressive renal disease is present, severe electrolyte depletion

## **Interactions**

### **DRUGS**

*aminoglycosides:* Increased risk of ototoxicity

*antihypertensives:* Increased hypotensive effect

*indomethacin*: Slowed increase in urine and sodium excretion, inhibited plasma renin activity

*lithium*: Reduced lithium renal clearance, increased risk of lithium toxicity

*nephrotoxic drugs*: Potential for adverse renal effects

*probenecid*: Reduced sodium excretion

## Adverse Reactions

**CNS:** Dizziness, **encephalopathy**, headache

**CV:** **Hypotension**

**EENT:** Ototoxicity

**ENDO:** Hyperglycemia

**GI:** Nausea

**GU:** **Azotemia**, elevated serum creatinine level

**MS:** Muscle spasms

**SKIN:** **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other:** Hyperuricemia, **hypocalcemia**, hypochloremia, **hypokalemia**, **hyponatremia**, hypovolemia

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## Nursing Considerations

**WARNING** Know that a patient hypersensitive to sulfonamides may be hypersensitive to bumetanide. Monitor such a patient closely when starting therapy.

- Expect to use parenteral route for patients with impaired GI absorption or in whom the oral route isn't practical. Switch to oral route, as prescribed, as soon as possible.
- Discard unused parenteral solution 24 hours after preparation.
- Assess fluid and electrolyte balance closely because bumetanide is a potent diuretic (40 to 60 times more potent than furosemide). Monitor fluid intake and output once every 8 hours, evaluate serum electrolyte levels when ordered, and assess for imbalances.

**WARNING** Be aware that high-dose or too-frequent administration can cause profound diuresis and water and electrolyte depletion, especially in elderly patients.

- Monitor serum potassium level regularly to check for hypokalemia, especially if patient takes a digitalis glycoside for heart failure or has aldosteronism, ascites, diarrhea, hepatic cirrhosis, potassium-losing nephropathy, or a history of ventricular arrhythmias.
- Assess for evidence of ototoxicity, such as tinnitus, daily. Rarely, drug may cause ototoxicity, especially with I.V. use, high doses, and increased frequency of dosing in a patient with renal impairment.
- Monitor results of renal function tests during therapy to detect adverse reactions.

## PATIENT TEACHING

- Advise patient to avoid hazardous activities until drug's CNS effects are known.

- Stress importance of monitoring fluid intake and output and watching for evidence of electrolyte imbalance, such as dizziness, headache, and muscle spasms.
- Review adverse reactions, and tell patient to report severe or persistent reactions.
- Review potassium-rich foods, and urge patient to include them in her daily diet.
- Urge patient to return for appropriate follow-up care, especially if she's receiving bumetanide for a chronic condition.
- Tell diabetic patient to monitor blood glucose level regularly and to notify prescriber about persistent hyperglycemia.
- Advise patient to report any changes in skin that are new, unusual, persistent, or severe.

## buprenorphine

**Butrans, Sublocade, Subutex**

**buprenorphine  
hydrochloride**

**Belbuca, Buprenex**

## Class, Category, and Schedule

*Pharmacologic class:* Opioid

*Therapeutic class:* Opioid analgesic

*Controlled substance schedule:* III

## Indications and Dosages

- *To control pain severe enough to require opioid treatment and for which alternative treatment options (i.e., nonopioid analgesics or opioid combination products) are inadequate or not tolerated*

## **I.V. OR I.M. INJECTION (BUPRENEX)**

**Adults and adolescents.** 0.3 mg every 6 hr or more, as needed. A second 0.3-mg dose may be given 30 to 60 min after first dose, if needed. I.V. injection given over at least 2 min.

***DOSAGE ADJUSTMENT*** For patients not at high risk for opioid toxicity, I.M. dose increased to 0.6 mg or frequency increased to every 4 hr, if needed, depending on pain severity and patient response. For elderly or debilitated patients and patients who have respiratory disease or also use another CNS depressant, I.V. or I.M. dose reduced by half.

**Children ages 2 to 12.** 2 to 6 mcg/kg every 4 to 6 hr, as needed.

- *To control severe chronic pain in patients requiring a continuous, around-the-clock opioid analgesic for an extended period of time for which alternative treatment options are inadequate*

## **TRANSDERMAL PATCH (BUTRANS)**

**Opioid-naïve adults and adults whose daily dose of oral morphine or equivalent was less than 30 mg.**

*Initial:* 5 mcg/hr, increased after 72 hr, as needed, to 10 mcg/hr with patch changed every 7 days. *Maximum:* 20 mcg/hr.

**Adults whose daily dose of oral morphine or equivalent was between 30 and 80 mg.**

*Initial:* Current around-the-clock opioid use tapered for up to 7 days to no more than 30 mg of morphine or equivalent

per day. Then a 10 mcg/hr patch applied, increased after 72 hr, as needed, to 20 mcg/hr with patch changed every 7 days.

*Maximum:* 20 mcg/hr.

## **BUCCAL FILM (BELBUCA)**

**Opioid-naïve adults and adults whose daily dose of oral morphine or equivalent was less than 30 mg.**

*Initial:* 75 mcg once daily, or if tolerated, every 12 hr for at least 4 days, then increased to 150 mcg every 12 hr. Then, dosage increased in increments of 150 mcg every 4 or more days, as needed. *Maximum:* 900 mcg every 12 hr.

**Adults whose daily dose of oral morphine or equivalent was between 30 and 89 mg.** *Initial:* 150 mcg every 12 hr, then increased in increments of 150 mcg every 4 or more days, as needed. *Maximum:* 900 mcg every 12 hr.

**Adults whose daily dose of oral morphine or equivalent was between 90 and 160 mg.** *Initial:* 300 mcg every 12 hr, then increased in increments of 150 mcg every 4 or more days, as needed. *Maximum:* 900 mcg every 12 hr.

***DOSAGE ADJUSTMENT*** For patients with oral mucositis or severe hepatic impairment, initial dose and subsequent titrations, dosage decreased by half.

➤ *To treat opioid dependence*

## **SUBLINGUAL TABLETS (SUBUTEX)**

**Adults.** *Induction:* 8 mg daily on day 1 followed by 16 mg daily on days 2 to 4. *Maintenance:* 4 to 24 mg daily, with increases or decreases in 2- to 4-mg increments, as needed. *Maximum:* 24 mg daily.

***DOSAGE ADJUSTMENT*** For patients with severe hepatic impairment, initial dose and subsequent titrations, dosage decreased by half.

- *To treat moderate to severe opioid use disorder in patients who have initiated treatment with a transmucosal buprenorphine-containing product, followed by dose adjustment for a minimum of seven days*

## **SUBCUTANEOUS INJECTION (SUBLOCADE)**

**Adults.** 300 mg monthly for first 2 months followed by maintenance dose. *Maintenance:* 100 mg monthly. Maintenance dose may be increased to 300 mg monthly, if needed.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
I.V.	Under 15 min	Under 1 hr	6-10 hr*
I.M.	15 min	1 hr	6-10 hr*
Transdermal	Unknown	17 hr	Unknown
Sublingual	Unknown	1.40 hr	Unknown

\* 4 to 5 hr in children ages 2 to 12.

## **Mechanism of Action**

May bind with CNS receptors to alter the perception of and emotional response to pain. Buprenorphine may act by displacing narcotic agonists from their binding sites and competitively inhibiting their actions.

## **Incompatibilities**

Don't give I.V. buprenorphine through the same I.V. line as diazepam or lorazepam.

## **Contraindications**

Acute or severe bronchial asthma in an unmonitored setting or in the absence of resuscitative equipment, hypersensitivity to buprenorphine or its components, known or suspected GI obstruction including paralytic ileus, significant respiratory depression

## Interactions

### DRUGS

*anticholinergic drugs*: Increased risk of urinary retention and/or severe constipation that could lead to paralytic ileus  
*antimigraine agents, cyclobenzaprine; dextromethorphan; dolasetron; granisetron; linezolid; MAO inhibitors; methylene blue; ondansetron; palonosetron; selected psychiatric drugs such as amoxapine, buspirone, lithium, mirtazapine, nefazodone, trazodone, vilazodone; selective serotonin reuptake inhibitors; serotonin-norepinephrine reuptake inhibitors; St. John's wort; tricyclic antidepressants; tryptophan*: Increased risk of serotonin syndrome

*benzodiazepines, CNS depressants, other opioids, sedating antihistamines, tricyclic antidepressants*: Increased risk of significant respiratory depression and other life-threatening adverse effects

*CNS depressants, MAO inhibitors*: Additive hypotensive and respiratory and CNS depressant effects of these drugs that may be life-threatening

*CYP3A4 inducers such as carbamazepine, phenytoin, rifampin*: Possibly decreased plasma concentration of buprenorphine

*CYP3A4 inhibitors such as azole-antifungals (ketoconazole), macrolide antibiotics (erythromycin), protease inhibitors (ritonavir)*: Increased plasma concentration of

buprenorphine, causing increased or prolonged opioid effects

*diuretics*: Possibly reduced effectiveness of diuretics

*mixed agonist/antagonist and partial agonist opioid*

*analgesics such as butorphanol, nalbuphine, pentazocine*:

Possibly reduced analgesic effect of buprenorphine and/or precipitate withdrawal symptoms

*muscle relaxants*: Possibly enhanced neuromuscular blocking action of skeletal muscle relaxants; increased degree of respiratory depression

*non-nucleoside reverse transcriptase inhibitors (NNRTIs)*

*such as delavirdine, efavirenz*: Significant pharmacokinetic interactions that has potential to affect action of buprenorphine

*protease inhibitors such as atazanavir, ritonavir*: Increased levels of buprenorphine causing symptoms of opioid excess, including increased sedation

### **Activities**

*alcohol use*: Increased serum buprenorphine levels possibly resulting in fatal overdose owing to CNS and respiratory depression

## **Adverse Reactions**

**CNS**: **CNS depression**, dizziness, headache, sedation, **seizures**, vertigo

**CV**: **Bradycardia**, hypertension, **hypotension**, **QT prolongation**

**EENT**: Miosis; *Sublingual form*: Burning mouth syndrome, glossitis, mucosal erythema, oral hypoesthesia, stomatitis

**ENDO**: **Adrenal insufficiency (rare)**

**GI**: Elevated liver enzymes or serum amylase level, **hepatitis**, **hepatotoxicity**, jaundice, nausea, spasm of the

sphincter of Oddi, vomiting

**GU:** Androgen deficiency with chronic use, decreased libido, erectile dysfunction, impotency, infertility, lack of menstruation

**RESP:** **Bronchospasm, hypoventilation, respiratory depression**

**SKIN:** Diaphoresis, pruritus, rash, urticaria

**Other:** **Anaphylaxis; angioedema;** application-site inflammation, burns, discharge and vesicle occurrence; injection-site pain, redness, and swelling; physical and psychological dependence

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm but neonatal opioid withdrawal syndrome may occur in newborn infants of mothers receiving the drug.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Mothers who are opioid dependent on buprenorphine maintenance therapy may require additional analgesia during labor.
- Be aware that, as with all opioids, use of the drug prior to delivery may result in respiratory depression in the newborn.

### LACTATION

- Drug is present in breast milk.
- Breastfeeding is usually not recommended.

- If breastfeeding occurs, mother should be instructed to monitor infant for breathing difficulties and drowsiness.

## REPRODUCTION

- Chronic use of opioids may cause reduced fertility in females of childbearing age and in males.
- It is not known whether these effects on fertility are reversible.

## Nursing Considerations

- Evaluate patient's risk for abuse and addiction prior to the start of buprenorphine therapy, as excessive use of drug may lead to abuse, addiction, misuse, overdose, and possibly death. Be prepared to monitor patient's intake throughout therapy. Because of the potential risks associated with buprenorphine therapy, be aware that the FDA now requires a Risk Evaluation and Mitigation Strategy (REMS) for buprenorphine use.
- Know that the transdermal patch should not be used in patients whose prior total daily dose of opioid use is greater than 80 mg of oral morphine equivalents per day because the maximum 20 mcg/hr dosage may not provide adequate analgesia. An alternate analgesic should be considered.
- Be aware that opioids like buprenorphine should not be given to women during pregnancy and labor and while breast feeding, as the newborn or infant may experience neonatal opioid withdrawal syndrome (NOWS). This syndrome may exhibit as excessive or high-pitched crying, poor feeding, rapid breathing, or trembling.

**WARNING** Be aware that opioid therapy like buprenorphine should only be used concomitantly with benzodiazepine therapy in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of the opioid to be limited. Monitor patient closely for signs and symptoms of decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

- Use buprenorphine cautiously in patients with adrenal insufficiency, alcohol withdrawal syndrome, acute alcoholism, biliary tract dysfunction, CNS depression, coma, hypothyroidism, kyphoscoliosis, myxedema, prostatic hypertrophy, psychosis, severe hepatic or renal impairment, toxic psychosis, or urethral stricture. Also use cautiously in patients who take a drug that decreases hepatic clearance, are known drug abusers, or have been addicted to opioids.
- Use drug cautiously in patients with head injury, intracranial lesions, or other conditions that could increase CSF pressure. Be particularly cautious when administering drug to patients with chronic obstructive pulmonary disease or cor pulmonale and in patients who have decreased respiratory reserve, hypoxia, hypercapnia, or preexisting respiratory depression.
- Be aware that Subutex trade name of buprenorphine should not be used to treat pain because of the risk of overdose in opioid-naïve patients.
- Know that to avoid causing withdrawal, drug shouldn't be given for opioid dependence until signs of withdrawal occur.
- Expect to obtain liver function tests prior to initiation of buprenorphine therapy and periodically throughout therapy because drug may cause hepatic dysfunction ranging from transient asymptomatic elevations in liver enzymes to hepatic failure and death. Acute hepatitis may also occur and, in some cases, require the drug to be discontinued, although in other cases even a dosage reduction of buprenorphine may not be needed. Monitor patient closely and report any signs and symptoms of hepatic dysfunction to prescriber.
- Know that an extended-release formulation (Sublocade) given as a subcutaneous injection monthly is available for patients who have initiated treatment with a transmucosal buprenorphine-containing product, followed by dose adjustment for a minimum of seven days. Administer drug subcutaneously into the abdomen only. Administer only using the syringe and safety needle included with the product. Administer monthly with a minimum of 26 days between doses. If Sublocade is discontinued, monitor patient for several months for signs and symptoms of withdrawal and treat as prescribed.
- Remove subcutaneous form (Sublocade) from refrigerator at least 15 minutes prior to administration to allow drug to reach room temperature. Then remove the foil pouch and safety needle from the carton. Open pouch and remove the syringe. Check the solution, which should be colorless to yellow to amber. Attach the safety needle. Do not remove the plastic cover from the needle at this time. Choose an injection site on the patient's abdomen between the transpyloric and transtuberular planes that has adequate subcutaneous tissue that is free of excessive pigment,

lesions, or nodules. Also, do not inject into an area where the skin is bruised, infected, irritated, reddened, or scarred in any way. Have patient assume a supine position. Clean injection site with an alcohol swab. To avoid irritation, rotate injection sites, which requires keeping a monthly log of sites used. Remove excess air from syringe and administer drug. Use a slow, steady push to inject the drug until all of the drug is given. Withdraw the needle, lock the needle guard, and discard the syringe.

- Know that the drug (Sublocade) may be removed from a subcutaneous site surgically under local anesthesia within 14 days of the injection. If removed, monitor patient for signs and symptoms of withdrawal and treat appropriately, as prescribed.
- Be aware that an implantable form of the drug (Probuphine) may be prescribed for a patient who has achieved and sustained prolonged clinical stability on low-to-moderate doses of a transmucosal buprenorphine-containing product (i.e., doses of no more than 8 mg/day). It is not appropriate for patients new to a treatment program nor for those who have not achieved clinical stability. Because of the risks related to insertion and removal of the implant, the implant has restricted use.
- Give I.V. form over at least 2 minutes.
- Inspect injection site for local reactions; don't use the same site twice.
- Monitor vital signs and response to drug often, especially after giving first dose and if patient develops a fever. Be aware that drug may cause severe hypotension, including orthostatic hypotension and syncope in ambulatory patients.

**WARNING** Monitor patient closely for respiratory depression, especially in cachectic, debilitated, or elderly patients; when initiating and titrating dosages; or when other drugs that depress respiration are given together. Report respiratory depression immediately, because respiratory arrest may occur. Be prepared to provide emergency supportive care.

- Monitor patient with a seizure disorder, as buprenorphine may worsen seizure control.
- Assess elderly patients for signs and symptoms of toxicity or overdose, as these patients may be at increased risk because of decreased cardiac, hepatic, or renal function and the presence of concomitant disease and other drug therapy.

**WARNING** Know that many drugs may interact with opioids like buprenorphine to cause serotonin syndrome. Monitor patient closely for signs and symptoms such as agitation, diaphoresis, diarrhea, fever, hallucinations, labile blood pressure, muscle twitching or stiffness, nausea, shakiness, shivering, tachycardia, trouble with coordination, or vomiting. Notify prescriber at once because serotonin syndrome may be life-threatening. Be prepared to discontinue drug, if possible and ordered, and provide supportive care.

- Monitor patient for adrenal insufficiency. Although rare, this can be life-threatening. Monitor patient for anorexia, dizziness, fatigue, hypotension, nausea, vomiting, or weakness. Notify prescriber if adrenal insufficiency is suspected and expect diagnostic testing to be done to determine if present. If diagnosis is confirmed, expect to administer corticosteroids and wean patient off buprenorphine, if possible.
- Do not discontinue therapy abruptly when buprenorphine therapy is no longer needed. Instead, expect a gradual downward titration of the dose to prevent signs and symptoms of withdrawal.
- Be aware that dosage adjustments of buprenorphine may be required during pregnancy even if patient was stable prior to pregnancy. Monitor pregnant patient closely for signs and symptoms of withdrawal and expect dosage to be adjusted as needed.

## **PATIENT TEACHING**

- Warn patient not to take more drug than prescribed and not to take it longer than absolutely needed, because excessive or prolonged use can lead to abuse, addiction, misuse, overdose, and possibly death.
- Advise patient that if a dose is missed, patient should take it as soon as it is remembered but if it is almost time for the next dose, the missed dose should be skipped and the next dose taken at the regular time. Dose should never be doubled to make up for a missed dose.

**WARNING** Warn patient not to consume alcohol or take benzodiazepines or other CNS depressants including other opioids, during buprenorphine therapy without

prescriber knowledge, as severe respiratory depression can occur that may lead to death.

**WARNING** Inform patient about potentially fatal additive effects of combining buprenorphine with benzodiazepines or other opioids. Instruct patient to inform all prescribers of buprenorphine use.

- Explain that buprenorphine may be habit forming. Urge her to notify prescriber if she develops any unusual or persistent symptoms.
- Instruct patient taking sublingual form to place tablets under her tongue until they dissolve. If patient takes more than two tablets per dose, tell her to place all tablets under her tongue at the same time. If they won't fit, tell her to place two at a time under her tongue until full dose has dissolved. Caution against swallowing tablets.

**WARNING** Instruct patient not to crush or dissolve tablet form of drug and then inject it as life-threatening infections, precipitated withdrawal, and other serious health problems could occur.

- Instruct patient prescribed the transdermal patch to place patch only on intact skin that is hairless and clean (washed with water only) and dry. If a hairless site is not available, instruct patient to clip, not shave, area prior to application. Emphasize importance of not applying patch to irritated skin. Inform patient patch must be applied immediately after its removal from pouch and placed on her upper outer arm, upper back, upper chest, or the side of her chest. Tell patient patch is to be worn for 7 days and that she should not cut the patch. If problems with adhesion occur, she may tape the edges of the patch with first-aid tape. If the patch should fall off during the 7-day interval, tell her to dispose of the patch and apply a new one at a different skin site. When removing the patch, tell patient to fold it over on itself and flush it down the toilet or seal it in the patch disposal unit provided and dispose of it in the trash.
- Instruct patient prescribed the buccal film form to first use his tongue to wet the inside of his cheek or rinse his mouth with water to wet the area. Then, he should place the yellow side of the film against the inside of his cheek after immediately removing it from the package and using clean, dry fingers, hold it in place for 5 seconds following which the film should be left in place until fully dissolved, usually within 30 minutes. Doing this time he should not manipulate the film with his tongue or fingers nor should he eat or drink anything until the film has dissolved. Remind

patient to dispose of unused film by removing from the foil packages and flush down the toilet. Discard foil packaging in the trash. He should not flush the drug down the toilet in the foil package.

- Tell patient receiving the drug as an extended-release subcutaneous injection that a lump may appear at injection site and last for several weeks. Tell patient not to massage or rub the injection site and to be careful of the placement of any belts or clothing waistbands so as not to irritate the site.
- Caution patient to keep drug, including patch form, out of the reach of others, especially children, as exposure to even one dose or patch could be fatal.
- Inform patient wearing a buprenorphine patch not to expose it to any external heat source such as heating pads, electric blankets, heat lamps, saunas, heated water beds or hot tubs, as absorption may be affected.
- Warn patient not to stop taking drug abruptly.
- Advise patient to get up slowly from a lying or sitting position to avoid a sudden drop in blood pressure.
- Caution patient to avoid hazardous activities while receiving buprenorphine.
- Instruct patient not to drink alcohol or take CNS depressants or sleep aids without checking with prescriber first.
- Inform patient that long-term use of opioids like buprenorphine may decrease sex hormone levels causing decreased libido, erectile dysfunction, impotence, infertility, or lack of menstruation. Encourage patient to report any such symptoms.
- Advise patient to report any persistent, severe, or unusual signs and symptoms to prescriber.
- Advise patient to keep buprenorphine in a safe place and to protect it from theft because of it being an opioid.
- Advise patient to notify prescriber if she becomes pregnant or is breastfeeding, as drug may have to be discontinued or dosage altered. Also tell mothers who are taking buprenorphine while breastfeeding to monitor their infant for breathing difficulties and increased drowsiness. If present, tell patient to stop breastfeeding and notify prescriber.
- Caution patient to dispose of expired, unwanted, or unused drug properly. Tell patients to visit the website: [www.fda.gov/drugdisposal](http://www.fda.gov/drugdisposal) for instructions. The drug can also be flushed down the toilet after removing foil, if present, if a drug take-back option is not available.

# bupropion hydrobromide

**Aplenzin**

# bupropion hydrochloride

**Forfivo XL, Wellbutrin, Wellbutrin SR, Wellbutrin XL, Zyban**

## Class and Category

*Pharmacologic class:* Aminoketone

*Therapeutic class:* Antidepressant, smoking cessation adjunct

## Indications and Dosages

➤ *To treat depression*

### **E.R. TABLETS (WELLBUTRIN SR)**

**Adults.** *Initial:* 150 mg daily in morning for 3 days; then 150 mg twice daily with at least 8 hr between successive doses and, after several wk, 200 mg twice daily, as needed and tolerated. *Maximum:* 400 mg daily, given as 200 mg twice daily. Single doses should not exceed 200 mg/dose.

### **E.R. TABLETS (WELLBUTRIN XL)**

**Adults.** *Initial:* 150 mg daily in morning for 4 days; then 300 mg daily in the morning.

## **E.R. TABLETS (APLENZIN)**

**Adults.** *Initial:* 174 mg daily in the morning for 4 days. Then, if tolerated well, dosage increased to 348 mg daily in the morning.

## **E.R. TABLETS (FORFIVO XL)**

**Adults.** 450 mg once daily (not used to initiate treatment).

## **TABLETS (WELLBUTRIN)**

**Adults.** *Initial:* 100 mg twice daily, increased after 3 or more days to 100 mg three times daily with at least 6 hr between successive doses, as needed. *Maximum:* 450 mg daily or 150 mg/dose.

➤ *To aid in smoking cessation*

## **E.R. TABLETS (ZYBAN)**

**Adults.** *Initial:* 150 mg daily for 3 days and then 150 mg twice daily with at least 8 hr between each dose for 7 to 12 wk. *Maximum:* 300 mg daily or 150 mg/dose.

➤ *To prevent seasonal major depressive episodes in patient with seasonal affective disorder*

## **E.R. TABLETS (WELLBUTRIN XL)**

**Adults.** *Initial:* 150 mg once daily in morning starting in autumn, increased after 1 wk to 300 mg once daily in morning, if tolerated and needed. Decreased to 150 mg once daily 2 wk before stopping in early spring if dosage was 300 mg once daily.

## **E.R. TABLETS (APLENZIN)**

**Adults.** *Initial:* 174 mg once daily in morning starting in autumn, increased after 1 wk to 348 mg once daily in morning, if tolerated and needed. Decreased to 174 mg once daily 2 wk before stopping in early spring if dosage was 348 mg once daily.

**DOSAGE ADJUSTMENT** For patients with severe hepatic cirrhosis, no more than 75 mg daily of Wellbutrin, 100 mg daily or 150 mg every other day of Wellbutrin SR, 150 mg every other day of Wellbutrin XL or Zyban, and 174 mg every other day of Aplenzin. In renal impairment, dosage or frequency decreased on an individual basis.

Route	Onset	Peak	Duration
P.O.	1-3 wk	Unknown	Unknown

## Mechanism of Action

May inhibit dopamine, norepinephrine, and serotonin uptake by neurons, which significantly relieves evidence of depression.

## Contraindications

Hypersensitivity to bupropion or its components, seizure disorder or conditions that increase risk of seizures (i.e., abrupt discontinuation of alcohol, antiepileptic drugs, barbiturates or benzodiazepines; anorexia nervosa or bulimia; use within 14 days of an MAO inhibitor (MAOI), including reversible MAOIs such as linezolid or intravenous methylene blue; use of another form of bupropion concurrently

## Interactions

## DRUGS

*amantadine, levodopa*: Increased CNS adverse reactions to bupropion, *antidepressants, antipsychotics, concurrent use of other bupropion products, systemic corticosteroids,*

*theophylline*: Increased risk of seizures

*carbamazepine, phenobarbital, phenytoin*: Increased bupropion metabolism resulting in decreased bupropion exposure

*CYP2B6 inducers such as efavirenz, lopinavir, ritonavir*: Possibly decreased bupropion exposure and subsequent effectiveness

*CYP2B6 inhibitors such as clopidogrel, ticlopidine*: Possibly increased bupropion exposure and risk of adverse reactions

*digoxin*: Possibly decreased digoxin levels

*drugs metabolized by CYP2D6 such as certain*

*antidepressants (i.e. desipramine, fluoxetine, imipramine, nortriptyline, paroxetine, sertraline, venlafaxine).*

*antipsychotics (i.e. haloperidol, risperidone, thioridazine),*

*beta blockers (i.e. metoprolol), type IC antiarrhythmics (i.e. flecainide, propafenone)*: Increased blood exposure of these drugs and risk of adverse reactions

*MAO inhibitors including reversible MAOIs such as*

*linezolid and intravenous methylene blue*: Increased risk of acute bupropion toxicity and serious hypertensive reactions

*tamoxifen*: Possibly reduced effectiveness of tamoxifen

## ACTIVITIES

*alcohol use, recreational drug abuse*: Possible rare adverse neuropsychiatric events; reduced alcohol tolerance

## Adverse Reactions

**CNS:** Abnormal coordination, abnormal EEG, aggression, agitation, akathisia, akinesia, anxiety, aphasia, asthenia, CNS stimulation, **coma**, confusion, **CVA**, decreased concentration or memory, delirium, delusions, depersonalization, depression, dizziness, dream abnormalities, emotional lability, euphoria, extrapyramidal syndrome, fever, general or migraine headache, hallucinations, **homicidal ideation**, hostility, hyperkinesia, hypertonia, hyperesthesia, insomnia, irritability, mania, nervousness, neuralgia, neuropathy, panic, paranoia, paresthesia, parkinsonism, psychosis and other neuropsychiatric reactions, restlessness, **seizures**, sleep disorder, somnolence, **suicidal ideation**, syncope, tremor, unmasking tardive dyskinesia, vertigo

**CV:** **Arrhythmias**, chest pain, **complete AV block**, **extrasystoles**, hypertension, **MI**, orthostatic hypotension, palpitations, phlebitis, tachycardia, vasodilation

**EENT:** Acute-angle glaucoma, altered taste, amblyopia, blurred vision, dry mouth, gum hemorrhage, hearing loss, increased ocular pressure, increased salivation, mydriasis, pharyngitis, sinusitis, taste perversion, tinnitus

**ENDO:** Hyperglycemia, **hypoglycemia**, syndrome of inappropriate ADH secretion

**GI:** Abdominal pain, anorexia, colitis, constipation, diarrhea, dysphagia, esophagitis, flatulence, **GI hemorrhage**, GI ulceration, **hepatic dysfunction**, **hepatitis**, increased appetite, **intestinal perforation**, nausea, **pancreatitis**, vomiting

**GU:** Abnormal ejaculation, cystitis, decreased or increased libido, dyspareunia, dysuria, incontinence, painful erection, prostate disorder, salpingitis, urinary frequency and urgency, UTI, vaginal hemorrhage, vaginitis

**HEME:** Anemia, leukocytosis, **leukopenia**, lymphadenopathy, **pancytopenia**, **thrombocytopenia**

**MS:** Arthralgia; arthritis; muscle rigidity, twitching, and weakness; myalgia; **rhabdomyolysis**

**RESP:** **Bronchospasm**, cough, dyspnea, pneumonia, **pulmonary embolism**

**SKIN:** Alopecia, diaphoresis, **erythema multiforme**, **exfoliative dermatitis**, flushing, hirsutism, pruritus, rash, **Stevens-Johnson syndrome**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, generalized pain, hot flashes, **hyponatremia**, infection, serum sickness-like reaction, weight loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-844-405-6185 or visit <https://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/antidepressants/>.
- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that certain forms of bupropion are not approved for smoking cessation treatment, such as Aplenzin, Forfivo XL, Wellbutrin SR, and

## Wellbutrin XL

- Be aware that Forfivo XL should not be used in patients with hepatic or renal impairment because the only dosage available for Forfivo XL is 450 mg once daily, which may be too high a dose for the kidneys or liver to handle.
- Use cautiously in patients with renal impairment (all other brands); drug is excreted by kidneys.
- Know that Forfivo XL should never be used to initiate treatment of depression because the dose is too high. Only after the patient has received other bupropion products first and then requires a 450-mg dose should Forfivo XL be used.
- Assess patient's blood pressure before bupropion therapy begins and monitor periodically during therapy because bupropion may cause hypertension.
- Monitor depressed patients closely for worsened depression and increased suicide risk, especially when therapy starts or dosage changes.
- Monitor patient taking bupropion to stop smoking for neuropsychiatric symptoms, including suicidal ideation. If present, notify prescriber immediately, begin safety measures, and expect to discontinue drug.

**WARNING** Monitor patient for seizures. To reduce seizure risk, allow at least 4 hours (tablets) or 8 hours (E.R. tablets) between doses. Know that maximum dosage should not be exceeded and dosage reduction should be gradual because risk of seizures is dose-related.

- Use seizure precautions, especially in patients who are addicted to cocaine, opioids, or stimulants; have a history of CNS tumors, head trauma, or seizures; have hyponatremia, hypoxia, or severe hepatic cirrhosis; take drugs that lower the seizure threshold; take insulin or an oral antidiabetic; take OTC stimulants or anorectics; or use excessive alcohol, benzodiazepines, hypnotics, or sedatives.
- Know that using transdermal nicotine with bupropion may cause hypertension. Watch closely.

## PATIENT TEACHING

- Advise patient to take bupropion for 7 or more days before stopping smoking.
- Tell patient to swallow E.R. tablets whole and not to cut, crush, or chew them.
- Tell patient to take bupropion with food and to store tablets at room temperature while keeping tablets dry and out of the light.
- Urge patient to avoid or minimize consuming alcohol and sedatives during therapy and not to stop drug abruptly or exceed dosage prescribed because seizures may occur. Also warn patient not to abruptly stop taking antiseizure drugs or prescribed benzodiazepines or sedatives.

**WARNING** Advise patient to seek medical help immediately and stop taking drug if signs of rash, itching, hives, chest pain, shortness of breath, or swelling, especially of face, occurs.

- Urge caregivers to monitor depressed patient closely for worsened depression, especially when therapy starts or dosage changes. Also inform caregiver that drug may cause a variety of neuropsychiatric adverse events that could be serious. If changes in behavior or thought patterns emerge with bupropion use, instruct caregiver to notify prescriber immediately.
- Alert patient that drug may cause mild pupillary dilation, which can lead to an episode of acute-closure glaucoma. Encourage him to have an eye exam to determine if he is susceptible to angle closure.
- Warn patient taking bupropion for smoking cessation by explaining that it may cause serious adverse effects, including suicidal thoughts and behavior. If present, patient should notify prescriber immediately and expect to discontinue drug.
- Alert patient that bupropion therapy may produce a false-positive urine screening test for amphetamines even after drug has been discontinued. Other tests may be required to distinguish bupropion from amphetamines.

## bupirone hydrochloride

**Bustab (CAN)**

## Class and Category

*Pharmacologic class:* Azaspirone

*Therapeutic class:* Anxiolytic

## Indications and Dosages

➤ *To manage anxiety*

### **TABLETS**

**Adults.** *Initial:* 7.5 mg twice daily increased by 5 mg daily at 2- to 3-day intervals until desired response occurs.

*Maintenance:* 20 to 30 mg daily (usual therapeutic range).

*Maximum:* 60 mg daily.

***DOSAGE ADJUSTMENT*** When used with CYP3A4 inhibitors, dosage lowered. When used with nefazodone, dosage decreased to 2.5 mg daily. Concomitant therapy with CYP3A4 inducers may require dosage to be increased.

Route	Onset	Peak	Duration
P.O.	1-4 wk	3-6 wk	Unknown

## Mechanism of Action

May act as a partial agonist at serotonin 5-hydroxytryptamine<sub>1A</sub> receptors in the brain, producing antianxiety effects.

## Contraindications

Hypersensitivity to buspirone or its components, severe hepatic or renal impairment

# Interactions

## DRUGS

*CYP3A4 inducers, such as certain anticonvulsants (carbamazepine, phenobarbital, phenytoin) and dexamethasone:* Possibly increased rate of buspirone metabolism and decreased effectiveness of buspirone

*CYP3A4 inhibitors, such as ketoconazole and ritonavir:* Possibly inhibited buspirone metabolism and increased blood level of buspirone

*diltiazem, erythromycin, itraconazole, nefazodone, nordiazepam, verapamil:* Increased blood level and adverse effects of buspirone

*haloperidol:* Increased haloperidol level

*MAO inhibitors:* Increased risk of hypertension

*rifampin:* Decreased blood buspirone level and pharmacodynamic effects

## FOODS

*any food:* Possibly decreased buspirone clearance

*grapefruit juice:* Increased blood buspirone level

## Adverse Reactions

**CNS:** Akathisia, anger, ataxia, cogwheel rigidity, confusion, decreased concentration, depression, dizziness, dream disturbances, drowsiness, dyskinesias, dystonia, excitement, extrapyramidal symptoms, fatigue, headache, hostility, insomnia, lack of coordination, light-headedness, mood swings, nervousness, paresthesia, parkinsonism, restless leg syndrome, restlessness, **serotonin syndrome**, transient recall impairment, tremor, weakness

**CV:** Chest pain, palpitations, tachycardia

**EENT:** Blurred vision, dry mouth, nasal congestion, pharyngitis, tinnitus, tunnel vision

**GI:** Abdominal or gastric distress, constipation, diarrhea, nausea, vomiting

**GU:** Urine retention

**MS:** Myalgia

**SKIN:** Diaphoresis, ecchymosis, rash, urticaria

**Other:** **Angioedema**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Drug use during breastfeeding is not recommended.

## Nursing Considerations

- Use buspirone cautiously in patients with hepatic or renal impairment.
- Institute safety precautions because of possible adverse CNS reactions.
- Follow closely if patient is being withdrawn from long-term therapy with benzodiazepines or other sedative-hypnotic drugs while starting buspirone because buspirone won't prevent withdrawal symptoms.

### PATIENT TEACHING

- Advise patient to take buspirone consistently, either always with or always without food.
- Caution patient to avoid drinking large amounts of grapefruit juice.
- Inform patient that 1 to 2 weeks of therapy may be needed before she notices drug's antianxiety effect.
- Emphasize the importance of not taking more buspirone than prescribed.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.

## butorphanol tartrate

### Class, Category, and Schedule

*Pharmacologic class:* Opioid agonist-antagonist

*Therapeutic class:* Anesthesia adjunct, opioid analgesic

*Controlled substance schedule:* IV

### Indications and Dosages

➤ *To manage pain*

#### I.V. INJECTION

**Adults.** 0.5 to 2 mg (usually 1 mg) every 3 to 4 hr, as needed.

#### I.M. INJECTION

**Adults.** 1 to 4 mg (usually 2 mg) every 3 to 4 hr, as needed. *Maximum:* 4 mg/single dose.

#### NASAL INHALATION

**Adults.** 1 mg (1 spray) in one nostril. Dose repeated after 60 to 90 min, as needed; two-dose sequence repeated every 3 to 4 hr after the second dose of the sequence, as needed. For severe pain, 2 mg (1 spray in each nostril) every 3 to 4 hr, as needed.

**DOSAGE ADJUSTMENT** Dose reduced to 1 spray in one nostril for elderly patients and those with impaired hepatic or renal function. Dose repeated after 90 to 120 min, as needed; two-dose sequence repeated every 6 hr or more, as needed.

➤ *As adjunct to provide preoperative anesthesia*

## **I.M. INJECTION**

**Adults.** Individualized. *Usual:* 2 mg 60 to 90 min before surgery.

➤ *As adjunct to provide anesthesia*

## **I.V. INJECTION**

**Adults.** Individualized. *Usual:* 1 to 4 mg and then supplemental doses of 0.5 to 1 mg, as needed. Total usually required during surgery is 60 to 180 mcg/kg.

➤ *Adjunct to balanced anesthesia*

## **I.V. INJECTION**

**Adults.** 2 mg shortly before induction and/or 0.5 to 1 mg in increments during anesthesia, as needed.

➤ *To relieve pain during labor*

## **I.M INJECTION, I.V. INJECTION**

**Pregnant women at full term in early labor.** 1 to 2 mg repeated in 4 hr.

**DOSAGE ADJUSTMENT** For elderly patients and patients with impaired hepatic or renal function, initial parenteral dose kept at 1 mg followed, if needed, by 1 mg in 90 to 120 min and dosage interval for subsequent doses increased to at least 6 hr or more.

Route	Onset	Peak	Duration
I.V.	2-3 min	30 min	2-4 hr
I.M.	10-30 min	30-60 min	3-4 hr
Inhalation	15 min	1-2 hr	4-5 hr

## Mechanism of Action

Binds with specific CNS receptors to alter the perception of and emotional response to pain.

## Contraindications

Acute or severe bronchial asthma in an unmonitored setting or in the absence of resuscitative equipment; GI obstruction, including paralytic ileus; hypersensitivity to butorphanol or its components (including the preservative benzethonium chloride); significant respiratory depression

## Interactions

### DRUGS

*benzodiazepines, other CNS depressants:* Additive CNS depression that can be significant, causing coma, prolonged sedation, or significant respiratory depression  
*Nasal vasoconstrictors, such as oxymetazoline:* Decreased absorption rate and delayed onset of butorphanol  
*serotonergic drugs:* Increased risk of serotonin syndrome

## ACTIVITIES

*alcohol use:* Additive CNS depression that could be significant

## Adverse Reactions

**CNS:** Anxiety, confusion, difficulty making purposeful movements, difficulty speaking, dizziness, euphoria, floating feeling, headache, insomnia (with nasal form), lethargy, nervousness, paresthesia, sensation of heat, somnolence, syncope, tremor, vertigo

**CV:** Chest pain, **hypotension**, palpitations, tachycardia, vasodilation

**EENT:** Blurred vision, dry mouth, ear pain, epistaxis, nasal congestion or irritation (with nasal form), pharyngitis, rhinitis, sinus congestion, sinusitis, tinnitus, unpleasant taste

**GI:** Anorexia, constipation, epigastric pain, nausea, vomiting

**RESP:** **Apnea**, bronchitis, cough, dyspnea, **respiratory depression, shallow breathing**, upper respiratory tract infection

**SKIN:** Clammy skin, pruritus

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LABOR & DELIVERY**

- Drug may prolong labor.
- Use of drug during pregnancy for prolonged time may cause neonatal opioid withdrawal syndrome in infants causing respiratory depression and excessive sedation in the neonate shortly after birth.

## **LACTATION**

- Drug may be present in breast milk.
- Patient should check with prescriber before breastfeeding
- If breastfeeding occurs, mother should be instructed to monitor infant for breathing difficulties and drowsiness.
- Withdrawal symptoms can occur in breastfed infants when mother stops taking drug or breastfeeding stops.

## **Nursing Considerations**

- Know that butorphanol should be used cautiously, if at all, in patients with depression, suicidal tendency, history of drug abuse, or hepatic or renal dysfunction.
- Use it cautiously, if at all, in patients with head injury because drug can raise CSF pressure. Because it can increase cardiac workload, use with extreme caution in patients with acute MI, ventricular dysfunction, or coronary insufficiency.
- Be aware that butorphanol has a high potential for abuse.
- Monitor patient after first dose of nasal form; hypotension and syncope may occur.
- Take safety precautions because butorphanol causes CNS depression.
- Assess respiratory status closely because drug causes respiratory depression, which could become life-threatening.
- Monitor blood pressure often after giving drug. If severe hypertension develops (rare), stop drug at once and notify prescriber. If patient isn't narcotic-dependent, expect to administer naloxone to reverse butorphanol's effects.

## PATIENT TEACHING

- Emphasize the importance of taking butorphanol exactly as prescribed because it can be addictive. Warn patient not to increase the dose or decrease the dosage interval without consulting prescriber.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Tell patient to avoid alcohol and other CNS depressants, including OTC drugs, while taking butorphanol because of additive adverse CNS reactions.
- Teach patient how to use nasal form properly by giving these instructions:  
After blowing nose to clear the nostrils, pull clear cover from the pump unit and remove protective clip from its neck. Prime pump unit by placing the nozzle between first and second fingers with thumb on the bottom of the bottle. Then pump sprayer unit firmly and quickly until a fine spray appears (7 or 8 strokes). Insert spray tip about 1 cm (one-third inch) into one nostril, pointing tip toward the back of the nose. Close other nostril with one finger and tilt head slightly forward. Then pump sprayer firmly and quickly by pushing down on the pump unit's finger grips and against the thumb at the bottom of the bottle. Sniff gently with mouth closed. After spraying, remove pump from nose, tilt head back, and sniff gently for a few more seconds. Then replace protective clip and clear cover.

# C

## cabergoline

**Dostinex**

### Class and Category

*Pharmacologic class:* Dopamine agonist

*Therapeutic class:* Antihyperprolactinemic

### Indications and Dosages

- *To treat idiopathic or pituitary adenoma-induced hyperprolactinemic disorders*

#### **TABLETS**

**Adults.** 0.25 mg twice/wk. Increased by 0.25 mg twice/wk at 4-wk intervals, if needed, up to 1 mg twice/wk.

Route	Onset	Peak	Duration
P.O.	Unknown	48 hr	Up to 14 days

### Mechanism of Action

Binds with dopamine D<sub>2</sub> receptors to block prolactin synthesis and secretion by the anterior pituitary gland, thereby reducing the serum prolactin level.

# Contraindications

History of cardiac valvular, pericardial, pulmonary, or retroperitoneal fibrotic disorders; hypersensitivity to cabergoline, ergot derivatives, or their components; uncontrolled hypertension

# Interactions

## DRUGS

*antihypertensives*: Increased risk of hypotension  
*dopamine antagonists (butyrophenones, metoclopramide, phenothiazines, or thioxanthenes)*: Decreased cabergoline effectiveness

# Adverse Reactions

**CNS**: Aggression, asthenia, compulsive/impulse control behaviors (hypersexuality, increased libido, pathological gambling), depression, fatigue, headache, nervousness, paresthesia, somnolence, psychotic disorder, vertigo

**CV**: Orthostatic hypotension, **valvulopathy**

**EENT**: Dry mouth

**ENDO**: Breast pain

**GI**: Abdominal pain, constipation, diarrhea, flatulence, indigestion, nausea, vomiting

**GU**: Dysmenorrhea, increased libido

**RESP**: Pulmonary effusion, **pulmonary fibrosis**

**SKIN**: Alopecia

**Other**: Extracardiac fibrotic reactions

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Drug is not recommended for women who are or wish to breastfeed because drug action may interfere with lactation.
- A decision should be made to discontinue breastfeeding or the drug.

# Nursing Considerations

- Ensure that patient has undergone a cardiovascular evaluation, including an echocardiogram to determine the presence of valvular disease prior to administering cabergoline because the presence of valvular disease is a contraindication to the use of cabergoline therapy.
- Obtain a chest x-ray, an erythrocyte sedimentation rate, and serum creatinine measurement, as ordered, prior to initiating cabergoline therapy and repeat during therapy if the patient develops any signs and symptoms of an extracardiac fibrotic reaction.
- Check serum prolactin level to assess cabergoline's effectiveness before each dose increase.
- Know that if patient has moderate to severe hepatic impairment, monitor closely for adverse reactions because of decreased cabergoline metabolism.
- Expect patient who takes cabergoline long term to undergo periodic reassessment of cardiac status, including echocardiography, because valvulopathy can occur with prolonged cabergoline use.
- Monitor erythrocyte sedimentation rate, as it may increase in a patient with pleural effusion or pleural fibrosis.

**WARNING** Monitor patient for evidence of overdose, such as hallucinations, light-headedness, nasal congestion, syncope, and tachycardia. If present, prescribe and treat as ordered.

## **PATIENT TEACHING**

- Urge patient to read and follow printed information that explains how to use cabergoline for best therapeutic results.
- Advise patient to take drug with meals to help decrease GI distress.
- Tell patient to take a missed dose as soon as possible within 1 to 2 days. If missed dose isn't remembered until it's time for the next dose, instruct him to double the dose if drug is generally well tolerated and doesn't cause nausea. If drug isn't well tolerated, instruct patient to consult prescriber before taking the missed dose.
- Urge patient to change positions slowly to avoid orthostatic hypotension. Tell him to notify prescriber if it occurs.
- Urge patient to keep regular appointments to monitor drug effectiveness.
- Advise patient that drug therapy will end when serum prolactin level is normal for 6 months. Explain that he'll need periodic monitoring to determine whether therapy should resume.
- Tell female patient of childbearing age to notify prescriber if she is, could be, or plans to become pregnant during therapy; drug may need to be discontinued.
- Inform patient that cabergoine may cause compulsive or impulse control behaviors such as hypersexuality, increased libido, and pathological gambling. If present, patient should contact prescriber because a dosage reduction or discontinuation of the drug may be needed. Caution patient to avoid gambling during therapy.

**calcitonin, salmon**

**Calcimar (CAN), Fortical, Miacalcin**

## Class and Category

*Pharmacologic class:* Hormone

*Therapeutic class:* Antihypercalcemic, anti-osteoporitic

## Indications and Dosages

- *To treat an early hypercalcemic emergency*

### **I.M. OR SUBCUTANEOUS INJECTION (MIACALCIN)**

**Adults.** *Initial:* 4 international units/kg every 12 hr. Increased after 1 or 2 days, if needed, to 8 international units/kg every 12 hr and then 8 international units/kg every 6 hr after 2 more days, if needed. *Maximum:* 8 international units/kg every 6 hr.

- *To treat postmenopausal osteoporosis in women who are at least 5 years postmenopausal*

### **I.M. OR SUBCUTANEOUS INJECTION (MIACALCIN)**

**Adults.** *Initial:* 100 international units daily.

### **NASAL SPRAY (FORTICAL)**

**Adults.** 200 international units (1 spray) daily, alternating nostrils.

- *To treat symptomatic Paget's disease of the bone*

### **I.M. OR SUBCUTANEOUS INJECTION (MIACALCIN)**

**Adults.** *Initial:* 100 international units daily.

Route	Onset	Peak	Duration
I.M., SubQ	In 15 min*	2 hr <sup>†</sup>	6–8 hr <sup>†</sup>
Nasal spray	10 min	Unknown	Unknown

\* For hypercalcemia; 6 to 24 mo for Paget's disease.

† For hypercalcemia; unknown for other indications.

## Mechanism of Action

Directly inhibits bone resorption. Besides reducing the serum calcium level, this action slows bone metabolism (a major factor in the development of Paget's disease) and calcium loss from the bone (a major factor in the development of osteoporosis).

## Contraindications

Hypersensitivity to calcitonin salmon or its components

## Interactions

### DRUGS

*lithium*: Possibly decreased lithium level

## Adverse Reactions

**CNS:** Agitation, anxiety, **CVA**, dizziness, fatigue, headache, insomnia, neuralgia, paresthesia, tremor, vertigo

**CV:** **Bundle branch block**, hypertension, **MI**, palpitations, peripheral edema, tachycardia, thrombophlebitis

**EENT:** Blurred vision; dry mouth; earache; epistaxis; eye pain; hearing loss; nasal irritation or ulceration (nasal

spray), lesions, or redness; pharyngitis; rhinitis; salty taste; sinusitis; taste perversion; tinnitus; vitreous floaters

**ENDO:** Goiter, hyperthyroidism

**GI:** Abdominal pain, anorexia, cholelithiasis, diarrhea, epigastric discomfort, flatulence, gastritis, **hepatitis**, increased appetite, nausea, thirst, vomiting

**GU:** Hematuria, nocturia, polyuria, **pyelonephritis**, renal calculi

**HEME:** Anemia

**MS:** Arthralgia, arthrosis, back or musculoskeletal pain, joint stiffness, polymyalgia rheumatica

**RESP:** Bronchitis, **bronchospasm**, cough, dyspnea, pneumonia, upper respiratory tract infection

**SKIN:** Alopecia, diaphoresis, eczema, flushing of face or hands, pruritus of earlobes, rash, ulceration, urticaria

**Other:** **Anaphylaxis**, **anaphylactic shock**, **angioedema**, antibody formation, feverish sensation, **hypocalcemia**, influenza-like symptoms, injection-site inflammation, lymphadenopathy, **malignancies**, mild tetanic symptoms

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.

- Drug is not recommended for women who are or wish to breastfeed because drug action may interfere with lactation.

## Nursing Considerations

- Expect to perform a skin test before giving drug if sensitivity to drug is suspected. Prepare a mixture of 10 international units/ml by withdrawing 0.05 ml from a 200-international unit solution in a tuberculin syringe and filling the syringe to 1 ml with sodium chloride for injection. Mix well, discard 0.9 ml, and inject 0.1 ml intradermally on the inner forearm. Observe the site for 15 minutes after injection. If you detect evidence of sensitivity, such as more than mild erythema or a wheal, notify prescriber.

**WARNING** Monitor all patients for hypersensitivity reactions, which could be severe. Have appropriate equipment and drugs present to treat a hypersensitivity reaction if it occurs. Notify prescriber, expect drug to be discontinued, and provide supportive care, as directed by prescriber.

- Monitor serum calcium level, as ordered, if patient receives calcitonin for hypercalcemia. During first several doses, keep parenteral calcium available in case the calcium level is inadvertently overcorrected.
- Know that if prescribed calcitonin dose exceeds 2 ml, expect to use I.M. route and multiple injection sites.
- Know that for patient receiving calcitonin for postmenopausal osteoporosis, know that hypocalcemia and other mineral metabolism disorders, such as vitamin D deficiency, must be corrected before calcitonin therapy begins. These patients should also be monitored during therapy for signs and symptoms of hypocalcemia such as muscle cramps, twitching, and seizures. Also, expect to give 1.5 g of supplemental calcium carbonate and at least 400 units of vitamin D daily. Plan to provide a balanced diet that includes foods high in calcium and vitamin D.
- Periodically examine patient using nasal spray for nasal ulcers. If severe ulceration of the nasal mucosa occurs (ulcers greater than 1.5 mm, ulcers penetrating below the mucosa, or ulcers causing heavy bleeding), notify prescriber and expect nasal spray form to be discontinued. Also, know that nasal spray should be discontinued for smaller or less severe ulcers until healing occurs.

- Assess for nausea, especially with the first dose. Nausea tends to decrease or disappear with continued use.
- Be aware if patient with Paget's disease relapses after treatment, check for antibody formation, as ordered.

## **PATIENT TEACHING**

- Tell patient to refrigerate injection or unopened nasal spray container.
- Teach patient to self-administer injections.
- Be aware that if patient has postmenopausal osteoporosis, teach her about dietary needs, including foods rich in calcium and vitamin D.
- Teach patient how to administer nasal spray, if ordered. Explain how to activate nasal pump by holding the bottle upright and depressing two white side arms toward the bottle six times. When bottle emits a faint spray, pump is activated. Tell patient to store activated nasal pump upright at room temperature and to discard it after 30 days.
- Instruct patient to place nozzle firmly into one nostril while holding head upright. Tell her to then depress the pump toward the bottle.
- Remind patient that she doesn't need to reactivate the pump before each dose.
- Instruct patient to report nasal symptoms to prescriber.

**calcitriol (1,25-dihydroxy-cholecalciferol)**

**Calcijex, Rocaltrol**

## **Class and Category**

*Pharmacologic class:* Vitamin D analogue

*Therapeutic class:* Antihypocalcemic

# Indications and Dosages

- *To treat hypocalcemia in dialysis patients*

## **CAPSULES, ORAL SOLUTION (ROCALTROL)**

**Adults.** *Initial:* 0.25 mcg daily. Increased by 0.25 mcg daily every 4 to 8 wk, if needed to achieve normal serum calcium level. *Maintenance:* 0.5 to 1 mcg daily.

## **I.V. INJECTION (CALCIJEX)**

**Adults.** *Initial:* 0.5 mcg every other day, 3 times/wk given rapidly at end of dialysis. Increased by 0.25 mcg or 0.5 mcg at 2- to 4-wk intervals, if needed. *Usual:* 0.5 mcg to 3 mcg 3 times a wk.

- *To treat hypocalcemia in predialysis patients*

## **CAPSULES, ORAL SOLUTION (ROCALTROL)**

**Adults and children age 3 and over.**

*Initial:* 0.25 mcg daily. Increased after 4 to 8 wk, if needed, to 0.5 mcg daily.

## **ORAL SOLUTION**

**Children up to age 3.** 10 to 15 ng/kg daily.

- *To treat hypoparathyroidism*

## **CAPSULES, ORAL SOLUTION (ROCALTROL)**

**Adults and children age 6 and over.** *Initial:* 0.25 mcg daily in the morning. Increased every 2 to 4 wk, if needed, to achieve normal serum calcium level. *Usual:* 0.5 to 2 mcg daily.

**Children ages 1 to 5.** 0.25 to 0.75 mcg daily in the morning.

Route	Onset	Peak	Duration
I.V.	Unknown	Unknown	3-5 days
P.O.	2-6 hr	10 hr	3-5 days

## Mechanism of Action

Binds to specific receptors on intestinal mucosa to increase calcium absorption from intestine. Drug may also regulate calcium ion transfer from bone to blood and stimulate calcium reabsorption in the distal renal tubules, making more calcium available in the body.

## Contraindications

Hypercalcemia, hypersensitivity to calcitriol or its components, vitamin D toxicity

## Interactions

### DRUGS

*calcium supplements*: Increased risk of hypercalcemia

*cholestyramine*: Decreased calcitriol absorption

*corticosteroids*: Possibly inhibits calcium absorption

*digitalis glycosides*: Possibly arrhythmias

*ketoconazole*: Decreased calcitriol level

*magnesium-containing antacids*: Hypermagnesemia

*mineral oil*: Decreased blood calcitriol level (with prolonged use of mineral oil)

*phenobarbital, phenytoin*: Decreased synthesis and blood level of calcitriol

*phosphate-binding agents*: Possibly altered phosphate transport in bone, intestine, and kidneys

*thiazide diuretics*: Hypercalcemia

*vitamin D*: Additive effects, including possible hypercalcemia

## Adverse Reactions

**SKIN:** Erythema multiforme, lip swelling, pruritus, rash, urticaria

**Other:** Anaphylaxis

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm. However, upon birth, the neonate may exhibit mild signs and symptoms of hypercalcemia for several days.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug may be present in breast milk.
- Breastfeeding should not be done during drug therapy

## Nursing Considerations

- Check to be sure patient receives enough calcium.
- Store drug at room temperature, and protect from heat and direct light.
- Monitor patient closely. In high-dose or long-term calcitriol therapy, be alert for vitamin D toxicity. Early evidence includes abdominal or bone pain, constipation, dry mouth, headache, metallic taste, myalgia, nausea, somnolence, vomiting, and weakness. Late evidence includes albuminuria, anorexia, arrhythmias, azotemia, conjunctivitis (calcific), decreased libido, elevated AST and ALT levels, elevated BUN level, vascular calcification, hypercholesterolemia, hypertension, hyperthermia, irritability, mild

acidosis, nephrocalcinosis, nocturia, pancreatitis, photophobia, polydipsia, polyuria, pruritus, rhinorrhea, and weight loss.

## **PATIENT TEACHING**

- Warn patient not to take other forms of vitamin D while taking calcitriol.
- Instruct patient to take a missed dose as soon as possible.
- Advise patient to notify prescriber immediately about possible toxicity, such as headache, irritability, nausea, photophobia, vomiting, weakness, and weight loss.

### **calcium acetate**

**Calphron, Eliphos, PhosLo, Phoslyra**

### **calcium carbonate**

**Apo-Cal (CAN), Calci-Mix, Calsan (CAN), Liqui-Cal, Liquid Cal-600, Titalac**

### **calcium chloride**

**Calciject (CAN)**

### **calcium citrate**

**Cal-C Cap, Cal-Cee, Citracal**

### **calcium gluconate**

# calcium lactate

**Cal-Lac**

## Class and Category

*Pharmacologic class:* Calcium salts

*Therapeutic class:* Antacid, antihypermagnesemic, antihyperphosphatemic, antihypocalcemic, calcium replacement, cardiotonic

## Indications and Dosages

➤ *To treat hyperphosphatemia*

### **CAPSULES, TABLETS (CALCIUM ACETATE)**

**Adults.** *Initial:* 2 capsules or tablets three times daily with meals. Dosage increased to reduce serum phosphorus level below 6 mg/dl as long as hypercalcemia doesn't develop.

*Usual:* 3 or 4 capsules or tablets three times daily with each meal.

### **ORAL SOLUTION (CALCIUM ACETATE)**

**Adults.** *Initial:* 10 ml with each meal. Dosage increased every 2 to 3 wk to reduce serum phosphorus levels to the target range, as long as hypercalcemia doesn't develop.

*Usual:* 15 to 20 ml with each meal.

➤ *To prevent hypocalcemia with oral supplementation*

### **CAPSULES, ORAL SUSPENSION, TABLETS (CALCIUM CARBONATE); EFFERVESCENT**

## **TABLETS, TABLETS (CALCIUM CITRATE); TABLETS (CALCIUM GLUCONATE OR LACTATE)**

**Adults.** 1,000 to 1,200 mg daily.

**Pregnant and breastfeeding women.** 1,000 to 1,300 mg daily.

**Children ages 9 to 18.** 1,300 mg daily.

**Children ages 4 to 8.** 1,000 mg daily.

**Children ages 1 to 4.** 700 mg daily.

**Children ages 7 to 12 months.** 260 mg daily.

**Infants up to 6 months.** 200 mg daily.

➤ *To provide antacid effects*

## **CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS (CALCIUM CARBONATE)**

**Adults and children age 12 and over.** 350 to 1,500 mg 1 hr after meals and at bedtime, as needed.

➤ *To provide emergency treatment for hypocalcemia*

## **I.V. INJECTION (CALCIUM CHLORIDE)**

**Adults.** 500 to 1,000 mg given slowly over 5 to 10 min, repeated as needed.

## **I.V. INFUSION (CALCIUM GLUCONATE)**

**Adults with mild hypocalcemia.** 1,000 to 2,000 mg infused over 2 hr.

**Adults with severe hypocalcemia but without seizure or tetany.** 0.5 mg/kg/hr, increased up to 2 mg/kg/hr, as needed. *Maximum:* 4,000 mg over 4 hr.

**Infants and children with severe hypocalcemia but without tetany.** 200 to 500 mg/kg/day as continuous infusion or divided every 6 hr as intermittent infusions.

**Neonates with severe hypocalcemia but without tetany.** 200 to 800 mg/kg/day by continuous infusion or divided every 6 hr as intermittent infusions.

## **I.V. INJECTION, I.V. INFUSION (CALCIUM GLUCONATE)**

**Adults with tetany.** 100 to 300 mg elemental calcium given as a bolus over 5 to 10 min, not to exceed 200 mg/min, followed by continuous infusion at 0.5 mg/kg/hr, increased to 2 mg/kg/hr, as needed, with rate adjusted, as needed, based on serum calcium levels.

**Children with tetany.** 100 to 200 mg/kg given as bolus over 10 min, not to exceed 100 mg/min, repeated after 6 hr, as needed. Alternatively, up to 500 mg/kg/day as continuous infusion with rate adjusted, as needed, based on serum calcium levels.

- *As adjunct to treat magnesium intoxication*

## **I.V. INJECTION (CALCIUM CHLORIDE)**

**Adults.** 500 to 1,000 mg given over 2 to 5 min and repeated if CNS depression persists.

- *To treat arrhythmias associated with hyperkalemia, hypermagnesemia, or hypocalcemia*

## **I.V. INJECTION (CALCIUM CHLORIDE)**

**Adults.** 500 to 1,000 mg given slowly over 5 to 10 min.

- *To treat beta-blocker overdose that is refractory to glucagon and high-dose vasopressor treatment*

## **I.V. INJECTION (CALCIUM CHLORIDE)**

**Adults.** 1,000 mg given via a central line.

- *To treat calcium channel blocker overdose*

## **I.V. INFUSION (CALCIUM CHLORIDE)**

**Adults.** 1,000 to 2,000 mg infused over 10 to 20 min, repeated every 20 min, as needed, up to 5 doses.

## **Mechanism of Action**

Increases levels of intracellular and extracellular calcium, which is needed to maintain homeostasis, especially in the nervous and musculoskeletal systems. Also plays a role in normal cardiac and renal function, respiration, coagulation, and cell membrane and capillary permeability. Helps regulate the release and storage of neurotransmitters and hormones. Oral forms also neutralize or buffer stomach acid to relieve discomfort caused by hyperacidity.

## **Contraindications**

Cardiac resuscitation with risk of existing digitalis toxicity or presence of ventricular fibrillation (I.V.), concurrent use of calcium supplements, hypercalcemia, hypersensitivity to calcium salts or their components, hypophosphatemia, renal calculi

## **Incompatibilities**

To avoid precipitation, don't give I.V. calcium chloride, or gluconate through same I.V. line as bicarbonates, carbonates, phosphates, sulfates, or tartrates.

## **Interactions**

### **DRUGS**

*bisphosphonates (alendronate, etidronate, ibandronate, risedronate):* Possibly decreased absorption of bisphosphonates  
*calcium supplements, magnesium-containing preparations:* Increased serum calcium or magnesium level, especially in patients with impaired renal function  
*digitalis glycosides:* Increased risk of arrhythmias  
*fluoroquinolones:* Reduced fluoroquinolone absorption by calcium carbonate  
*iron salts:* Decreased gastric iron absorption  
*levothyroxine:* Decreased absorption of levothyroxine  
*tetracyclines:* Decreased tetracycline absorption and blood level, leading to decreased anti-infective response  
*thiazide diuretics:* Possibly hypercalcemia  
*verapamil:* Reversed verapamil effects  
*vitamin D (high doses):* Excessively increased calcium absorption

## **FOODS**

*caffeine, high-fiber food:* Possibly decreased calcium absorption

## **ACTIVITIES**

*alcohol use (excessive), smoking:* Possibly decreased calcium absorption

## **Adverse Reactions**

**CNS:** Paresthesia (parenteral form)

**CV:** **Hypotension**, irregular heartbeat (parenteral form)

**GI:** Nausea or vomiting (parenteral form)

**SKIN:** Diaphoresis, flushing, or sensation of warmth (parenteral form)

**Other:** **Hypercalcemia**; injection-site burning, pain, rash, or redness (parenteral form)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Be aware that pregnancy may alter dosage needs for mother
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding. Dosage needs for mother may change if breastfeeding.

## Nursing Considerations

- Store at room temperature, and protect from heat, moisture, and direct light. Don't freeze.
- Warm solution to room temperature before parenteral administration.
- Keep patient in a recumbent position for 30 minutes after parenteral administration to prevent dizziness from hypotension.
- Administer I.V. calcium through an infusing I.V. solution using a small-bore needle inserted into a large vein to minimize irritation. Give calcium slowly to prevent excess calcium from reaching the heart and causing adverse cardiovascular reactions. Adverse reactions often result from too-rapid administration. If ECG tracings are abnormal or patient reports injection-site discomfort, expect to temporarily discontinue administration.

- Check regularly for infiltration because calcium causes necrosis. If infiltration occurs, stop infusion and tell prescriber immediately.
- Monitor serum calcium level, as ordered, and evaluate therapeutic response by assessing for Chvostek's and Trousseau's signs, which shouldn't appear.
- Be aware that calcium chloride injection contains three times as much calcium per milliliter as calcium gluconate injection.

## **PATIENT TEACHING**

- Urge patient to chew chewable tablets thoroughly before swallowing and to drink a glass of water afterward.
- Tell patient to shake bottle well before each use if suspension form is prescribed.
- Tell patient to dissolve calcium citrate effervescent tablets in water and drink immediately.
- Instruct patient to take calcium carbonate tablets 1 to 2 hours after meals and other forms with meals.
- Advise storing calcium at room temperature away from heat, moisture, and light. Warn against freezing suspension or syrup.
- Instruct patient to avoid taking calcium within 2 hours of another oral drug because of risk of interactions.
- Urge patient to ask prescriber before taking OTC drugs because of risk of interactions.
- Tell patient to avoid excessive use of tobacco and excessive consumption of alcoholic beverages, caffeine-containing products, and high-fiber foods because these substances may decrease calcium absorption.
- Remind patient to take calcium separate from other prescribed drugs. For example, tell the patient to take fluoroquinolone at least 2 hours before or 6 hours after calcium; if prescribed levothyroxine to take it at least 4 hours before or after calcium; if prescribed a tetracycline to take it at least 1 hour before calcium.

**canagliflozin**

# Invokana

## Class and Category

*Pharmacologic class:* Sodium-glucose co-transporter 2 (SGLT2) inhibitor

*Therapeutic class:* Antidiabetic

## Indications and Dosages

- *To control blood glucose level in type 2 diabetes mellitus; to reduce the risk of major adverse cardiovascular events such as nonfatal myocardial infarction and nonfatal stroke in patients with type 2 diabetes mellitus and established cardiovascular disease; to reduce the risk of end-stage kidney disease (ESKD), doubling of serum creatinine, cardiovascular death, and hospitalization for heart failure in patients with type 2 diabetes mellitus and diabetic nephropathy with albuminuria greater than 300 mg/day.*

## TABLETS

**Adults.** 100 mg once daily before first meal of the day, followed by dosage increase to 300 mg once daily before first meal of the day, if needed, and patient has a glomerular filtration rate of 60 ml/min or greater.

*Maximum:* 300 mg once daily before first meal of the day.

***DOSAGE ADJUSTMENT*** For patients with glomerular filtration rate less than 60 ml/min but at least 45 ml/min dosage limited to 100 mg once daily. For patients receiving an UDP-glucuronosyltransferase (UGT) enzyme inducer such as phenobarbital, phenytoin, rifampin, or ritonavir and have

a glomerular filtration rate of 60 ml/min or greater, dosage may be increased to 200 mg once daily if patient is tolerating 100 mg daily or increased to 300 mg once daily if patient is tolerating 200 mg daily. For patients receiving an UGT enzyme inducer as indicated above and the glomerular filtration rate is less than 60 ml/min, dosage increased to 200 mg once daily in patients tolerating 100 mg once daily.

## **Mechanism of Action**

Inhibits sodium-glucose co-transporter 2 (SGLT2) responsible for the majority of the reabsorption of filtered glucose from the tubular lumen in the kidneys. By inhibiting SGLT2, reabsorption of filtered glucose is reduced along with a lowering of the renal threshold for glucose, which increases urinary glucose excretion.

## **Contraindications**

Hypersensitivity to canagliflozin or its components, severe renal impairment (glomerular filtration rate less than 30 ml/min), use of dialysis

## **Interactions**

### **DRUGS**

*digoxin*: Possibly increased serum digoxin levels and digitalis toxicity

*insulin, insulin secretagogues*: Possibly increased risk of hypoglycemia

*phenobarbital, phenytoin, rifampin, ritonavir*: Decreased effectiveness of canagliflozin

## **Adverse Reactions**

**CNS:** Asthenia, excessive thirst, fatigue, postural dizziness, syncope

**CV:** Elevation of low-density lipoprotein cholesterol (LDL-C) and non-high-density lipoprotein cholesterol (non-HDL-C), **hypotension**, orthostatic hypotension

**ENDO:** **Hypoglycemia, ketoacidosis**

**EENT:** Dry mouth

**GI:** Abdominal pain, constipation, nausea, **pancreatitis**

**GU:** **Acute renal failure**, decreased glomerular filtration rate, elevated serum creatinine levels, genital mycotic infections, **necrotizing fasciitis of the perineum (Fournier's gangrene)**, **pyelonephritis**, polyuria, renal impairment, UTIs, vulvovaginal pruritus, **urosepsis**

**HEME:** Elevated hemoglobin

**MS:** Bone fracture, decreased bone density, lower limb amputation

**SKIN:** Erythema, photosensitivity, pruritus, rash, urticaria

**Other:** **Anaphylaxis, angioedema**, dehydration, elevated phosphate levels, **hyperkalemia, hypermagnesemia**

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm by adversely affecting kidney function of the fetus.
- Drug is not recommended during the second and third trimester of pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- Drug should not be given to women who are breastfeeding since kidney maturation in infant continues for 2 years following birth.

## Nursing Considerations

- Use drug cautiously in patients with chronic kidney insufficiency, congestive heart failure, decreased blood volume, and in patients taking medications such as angiotensin-converting enzyme inhibitors and angiotensin receptor blockers, diuretics, and NSAIDs because these conditions and treatments may predispose the patient to acute kidney injury while receiving canagliflozin. Ensure that kidney function has been assessed prior to start of canagliflozin therapy and then periodically thereafter.
- Know that patients with volume depletion should have the condition corrected before canagliflozin therapy is begun because drug causes intravascular volume contraction. Patients especially at risk for symptomatic hypotension caused by volume depletion include patients with impaired renal function, the elderly, patients taking either diuretics or drugs that interfere with the renin-angiotensin-aldosterone system, or patients with low systolic blood pressure.
- Expect drug to be temporarily discontinued in patients who develop a reduced oral intake, such as in an acute illness or fasting, or who experience excessive fluid losses because of significant heat exposure or gastrointestinal illness, to reduce risk of acute kidney injury.
- Be aware that canagliflozin dosage should only be increased in patients who have at least a glomerular filtration rate of 60 ml/min and need greater glucose control.
- Assess renal function, as ordered prior to starting canagliflozin therapy and then periodically thereafter, because canagliflozin may cause renal impairment, especially in patients with hypovolemia. Expect drug to be discontinued if patient develops acute kidney injury. Also monitor patient for a UTI, because canagliflozin increases risk of UTIs. Report promptly and expect to treat because the UTI can quickly become serious, developing into pyelonephritis and urosepsis.
- Monitor serum potassium levels regularly, as ordered, during canagliflozin therapy in patients with impaired renal function and in patients predisposed to hyperkalemia due to medications or other medical conditions.

- Monitor patient's blood glucose levels to determine effectiveness of canagliflozin therapy. Be aware that canagliflozin can increase urinary glucose excretion, leading to positive urine glucose tests, and should not be used to monitor glucose levels in patients with diabetes mellitus. Assess patient also receiving insulin or insulin secretagogues for hypoglycemia.

**WARNING** Monitor patient closely for ketoacidosis that may occur despite the patient having type 2 diabetes and even may be present even if a blood glucose level is less than 250 mg/dl. If signs and symptoms occur such as dehydration, fruity odor to breath, malaise, nausea, shortness of breath, and vomiting, notify prescriber and expect drug to be discontinued. Provide supportive care, as ordered.

- Be aware that patients with a history of genital mycotic infections, as well as uncircumcised males, are at greater risk for developing genital mycotic infections.

**WARNING** Report immediately signs and symptoms of necrotizing fasciitis of the perineum (Fournier's gangrene), a rare but serious and life-threatening necrotizing infection that has been linked to canagliflozin therapy. Report patient's complaints of erythema, pain or tenderness, or swelling in the genital or perineal area, along with fever or malaise, as treatment requires urgent surgical intervention along with immediate broad-spectrum antibiotic therapy. If confirmed, expect canagliflozin to be discontinued and an alternative treatment for glycemic control prescribed.

- Monitor patient's lipid levels and expect to treat if an elevation occurs.

**WARNING** Assess patient for hypersensitivity reactions such as angioedema and generalized urticaria, especially

within hours to days after canagliflozin therapy is begun. The hypersensitivity reaction can become severe, causing anaphylaxis. If hypersensitivity to canagliflozin occurs, expect drug to be discontinued and provide supportive care as ordered.

- Institute safety precautions to prevent falls because drug may increase risk of falls leading to bone fracture. The risk of bone fracture may occur as early as 12 weeks after therapy is begun.
- Be aware that canagliflozin has been linked to an increase in foot and leg amputations in patients receiving the drug. Assess patient's feet and legs regularly for any abnormalities and notify prescriber immediately if present. Be aware that patients may be at higher risk of lower-limb amputation if they have had diabetic foot sores or ulcers, have had blocked or narrowed blood vessels (usually in leg), have had damage to the nerves (neuropathy) in the leg, or have a history of amputation, heart disease, or are at risk for heart disease. Know that canagliflozin may be discontinued if abnormalities develop.

## **PATIENT TEACHING**

- Instruct patient to take canagliflozin before the first meal of the day. Tell her that if a dose is missed, she should take it as soon as she remembers unless it is almost time for the next dose. Then patient should skip the missed dose and take his normal dose of canagliflozin at the regular time. He should never double the dose.
- Urge patient not to skip doses or increase dosage without consulting prescriber. However, tell patient to notify prescriber if he is unable to take a normal amount of daily fluids due to illness or fasting or experiences an excessive loss of fluids from excessive perspiration or gastrointestinal illnesses, as drug may need to be temporarily withheld.
- Emphasize importance of reporting signs of hypoglycemia, such as anxiety, confusion, dizziness, excessive sweating, headache, and nausea.
- Tell patient to carry identification indicating that he has diabetes.
- Teach patient how to monitor his blood glucose level. Advise patient with diabetes mellitus not to use urine glucose tests to monitor her glycemic control, as drug will cause a false positive result. Review signs and symptoms of ketoacidosis with patient and urge her to seek immediate medical attention, if present, even if blood glucose level is less than 250 mg/dl.

- Inform patient that canagliflozin is not a substitute for diet and exercise management.
- Inform patient that drug may increase his risk for bone fractures and to take safety precautions to prevent falls.
- Advise patient to avoid direct sunlight and to wear sunscreen when outdoors.
- Instruct patient to notify prescriber right away if he notices any new pain or tenderness, sores or ulcers, or symptoms of infections in his feet or legs. Tell patient this is very important, because canagliflozin therapy increases the risk of lower-limb amputations.
- Advise patient to seek medical care promptly if pain or tenderness, redness, or swelling of the genitals or the area from the genitals back to the rectum occurs, along with a fever above 38°C (100.4°F) or malaise develops.

## candesartan cilexetil

**Atacand**

### Class and Category

*Pharmacologic class:* Angiotensin receptor blocker

*Therapeutic class:* Antihypertensive

### Indications and Dosages

➤ *To manage, or as adjunct in managing, hypertension*

#### ORAL SUSPENSION, TABLETS

##### **Adults.**

*Initial:* 16 mg daily. *Maintenance:* 8 to 32 mg daily or 4 to 16 mg every 12 hr. *Maximum:* 32 mg daily.

**Children ages 6 to 17 weighing more than 50 kg (110 lb).** *Initial:* 8 to 16 mg daily. *Maintenance:* 4 to 32 mg once daily or in divided doses daily. *Maximum:* 32 mg daily.

**Children ages 6 to 17 weighing 50 kg (110 lb) or less.** *Initial:* 4 to 8 mg daily. *Maintenance:* 4 to 16 mg once daily or in divided doses daily. *Maximum:* 16 mg daily.

**Children ages 1 to 6.** *Initial:* 0.20 mg/kg daily. *Maintenance:* 0.05 to 0.4 mg/kg daily or in divided doses daily. *Maximum:* 0.4 mg/kg daily.

***DOSAGE ADJUSTMENT*** For adult patients with moderate hepatic impairment, initial dosage reduced to 8 mg daily.

➤ *To treat heart failure in patients with an ejection fraction of 40% or less and NYHA class II–IV to reduce the risk of death from cardiovascular causes and reduce hospitalizations for heart failure*

## ORAL SUSPENSION, TABLETS

**Adults.** *Initial:* 4 mg daily for 2 wk; then doubled every 2 wk as tolerated until reaching target dose of 32 mg daily.

Route	Onset	Peak	Duration
P.O.	In 2 wk	4–5 wk	Unknown

## Mechanism of Action

Selectively blocks binding of angiotensin (AT) II to AT<sub>1</sub> receptor sites in many tissues, including adrenal glands and vascular smooth muscle. This inhibits vasoconstrictive and aldosterone-secreting effects of AT II, which reduces blood pressure.

## Contraindications

Concurrent aliskiren therapy in presence of diabetes, hypersensitivity to candesartan or its components

## Interactions

### DRUGS

*aliskiren (in presence of diabetes or renal impairment), angiotensin-converting enzyme inhibitors, angiotensin receptor blockers:* Increased risk of hypotension, hyperkalemia, and renal dysfunction

*lithium:* Increased blood lithium level

*NSAIDs:* Possible decreased renal function in patients who are elderly, volume-depleted, or have a compromised renal function

*potassium-sparing diuretics, potassium supplements, potassium-containing salt substitutes:* Possibly increased risk of hyperkalemia

## Adverse Reactions

**CNS:** Dizziness, headache

**CV:** **Hypotension**

**EENT:** Pharyngitis, rhinitis

**GI:** Elevated liver enzymes, **hepatitis**, impaired liver function

**GU:** Elevated BUN and serum creatinine levels

**HEME:** **Agranulocytosis, leukopenia, neutropenia**

**MS:** Back pain, **rhabdomyolysis**

**RESP:** Cough, upper respiratory tract infection

**SKIN:** Pruritus, rash, urticaria

**Other:** Angioedema, hyperkalemia, hyponatremia

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm.
- Drug given during the second or third trimester reduces fetal renal function and increases fetal and neonatal morbidity and death. Resulting oligohydramnios can cause fetal lung hypoplasia and skeletal malformations.
- Drug is contraindicated during pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Determine if patient has fluid or salt depletion prior to starting candesartan. If patient has known or suspected hypovolemia and/or salt depletion such as may occur with prolonged diuretic therapy, dietary salt restriction, dialysis, diarrhea or vomiting, expect to provide treatment, such as I.V. normal saline solution, as prescribed, to correct it before starting candesartan. Continue to monitor blood pressure throughout candesartan therapy, especially after a dosage increase.
- Monitor patient closely during major surgery and anesthesia because candesartan increases risk of hypotension by blocking renin-angiotensin system.
- Watch for elevated BUN and serum creatinine levels, especially if patient has heart failure or impaired renal function; drug may cause acute renal failure. Report significant or persistent increases immediately.

**WARNING** Know that if patient receives a diuretic or antihypertensive with candesartan, has heart failure, or is elderly, assess blood pressure often because of added risk of hypotension.

- Monitor patient for hypotension. If patient develops hypotension, expect to stop drug temporarily. Immediately place patient in supine position and prepare to give I.V. normal saline solution, as prescribed. Expect to resume therapy after blood pressure stabilizes.
- Monitor patient for fluid deficit. If patient receives a diuretic, provide hydration, as ordered, to help prevent hypovolemia. Watch for evidence, such as hypotension with dizziness and fainting. If patient has heart failure and develops hypotension, dosage of diuretic, candesartan, or both may be reduced when blood pressure stabilizes and therapy resumes.
- Check CBC for decreases in hemoglobin and hematocrit. If they're significant or persistent, notify prescriber immediately.

## PATIENT TEACHING

- Advise patient that full effects of candesartan may not occur for 4 to 5 weeks.
- Explain importance of lifestyle choices in controlling hypertension.
- Advise female patient of childbearing age to immediately report known or suspected pregnancy. Explain that if she becomes pregnant, candesartan will need to be discontinued as soon as possible and treatment started with another antihypertensive that's safe to use during pregnancy.

**cangrelor**

**Kengreal**

## Class and Category

*Pharmacologic class: P2Y<sub>12</sub> platelet inhibitor*

*Therapeutic class: Antiplatelet*

## **Indications and Dosages**

- *Adjunct to percutaneous coronary intervention (PCI) to reduce risk of periprocedural myocardial infarction, repeat coronary revascularization and stent thrombosis in patients who have not been treated with a P2Y<sub>12</sub> platelet inhibitor and are not being given a glycoprotein IIb/IIIa inhibitor*

### **I.V. INFUSION, I.V. INJECTION**

**Adults.** 30 mcg/kg IV bolus prior to PCI followed immediately by a 4 mcg/kg/min infusion for at least 2 hr or for the duration of PCI, whichever is longer.

## **Mechanism of Action**

Blocks ADP-induced platelet activation and aggregation by binding selectively and reversibly to the P2Y<sub>12</sub> receptor to prevent further signaling and platelet activation.

## **Contraindications**

Hypersensitivity to cangrelor or its components, significant active bleeding

## **Interactions**

### **DRUGS**

*thienopyridines such as clopidogrel, prasugrel:* Elimination effect of these drugs if given during cangrelor infusion; these drugs should be administered after cangrelor infusion is discontinued

## **Adverse Reactions**

**CNS:** Intracranial bleeding or hemorrhage

**CV:** Coronary artery dissection or perforation

**EENT:** Stridor

**GU:** Decreased renal function

**HEME:** Bleeding events

**RESP:** Bronchospasm, dyspnea

**Other:** Anaphylaxis including shock, angioedema

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LABOR & DELIVERY**

- Drug may increase risk of maternal bleeding and hemorrhage.
- Drug should be discontinued 1 hour prior to labor, delivery, or neuraxial blockade, if possible.

### **LACTATION**

- It is not known if drug is present in breast milk.

- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Reconstitute each 50 mg vial by adding 5 ml of sterile water for injection. Swirl gently until all material is dissolved. Avoid vigorous mixing. Allow any foam to settle. Ensure that the contents are fully dissolved and the reconstituted material is clear and colorless to pale yellow.
- Dilute reconstituted solution immediately with normal saline or 5% dextrose injection. For example, withdraw the contents from one reconstituted vial and add to one 250-ml saline bag. Mix the bag thoroughly. Know that patients weighing 100 kg or more will require a minimum of two bags. Diluted cangrelor is stable for 12 hr if diluted in 5% dextrose injection and 24 hr if diluted in normal saline and kept at room temperature.
- Administer via a dedicated I.V. line. Administer the bolus rapidly in less than 1 minute from the diluted bag via manual IV push or pump. Make sure the bolus is completely administered before the start of PCI and then start infusion immediately after administration of the bolus.
- Be aware that after cangrelor is discontinued, an oral P2Y<sub>12</sub> platelet inhibitor should be administered such as clopidogrel 600 mg after discontinuation of cangrelor, prasugrel 60 mg immediately after discontinuation of cangrelor, or ticagrelor 180 mg at any time during cangrelor infusion or immediately after discontinuation.
- Monitor patient closely for bleeding that can range from being minor to severe. Be prepared to treat bleeding events immediately and notify prescriber. Know that once cangrelor is discontinued, there is no antiplatelet effect after an hour.

**WARNING** Monitor patient closely for allergic reactions following administration. Alert prescriber immediately, if present, and be prepared to discontinue drug and provide supportive emergency care, as ordered.

## PATIENT TEACHING

- Tell patient to alert medical staff immediately if difficulty breathing occurs.

- Inform patient that the effects of cangrelor are gone after 1 hour of the drug being discontinued.

## captopril

### Class and Category

*Pharmacologic class:* Angiotensin-converting enzyme (ACE) inhibitor

*Therapeutic class:* Antihypertensive, vasodilator

### Indications and Dosages

- *To control hypertension*

#### **TABLETS**

**Adults.** *Initial:* 25 mg twice daily or three times daily. Increased to 50 mg twice daily or three times daily after 1 to 2 wk, if needed. If blood pressure isn't well controlled at this dosage and with the addition of a diuretic, dosage increased to 100 mg twice daily or three times daily and then, if needed, to 150 mg twice daily or three times daily while continuing diuretic. *Maximum:* 450 mg daily.

- *To control accelerated or malignant hypertension when temporary discontinuation of current antihypertensive therapy isn't practical or when prompt titration of blood pressure is needed*

#### **TABLETS**

**Adults.** *Initial:* 25 mg twice daily or three times daily while continuing diuretic but discontinuing current antihypertensive drug. Increased every 24 hr as needed until satisfactory response is obtained or maximum dosage is reached. *Maximum:* 450 mg daily.

➤ *To treat congestive heart failure*

## TABLETS

**Adults with normal or low blood pressure, who have been vigorously treated with diuretics.** *Initial:* 6.25 mg or 12.5 mg three times daily, increased gradually over several days to 50 mg three times daily. Further increases done in 2 wk intervals, as needed. *Maximum:* 450 mg daily.

**Adults.** *Initial:* 25 mg three times daily. Increased to 50 mg three times daily, as needed. After 14 days, increased to 100 mg three times daily and then to 150 mg three times daily, if needed. *Maximum:* 450 mg daily.

➤ *To treat left ventricular dysfunction after MI*

## TABLETS

**Adults.** *Initial:* 6.25 mg as single dose starting 3 days after MI and then 12.5 mg three times daily. Increased to 25 mg three times daily for several days and then again to maintenance dosage. *Maintenance:* 50 mg three times daily.

➤ *To treat diabetic nephropathy*

## TABLETS

**Adults.** 25 mg three times daily.

***DOSAGE ADJUSTMENT*** For patient with renal impairment, initial dosage reduced and smaller increments utilized for titration.

Route	Onset	Peak	Duration
P.O.	15-60 min	60-90 min	6-12 hr

## Mechanism of Action

By inhibiting angiotensin-converting enzyme, captopril:

- prevents conversion of angiotensin I to angiotensin II, a potent vasoconstrictor that also stimulates the adrenal cortex to secrete aldosterone. Inhibiting aldosterone increases sodium and water excretion, reducing blood pressure and water retention.
- may inhibit renal and vascular production of angiotensin II.
- decreases serum angiotensin II level and increases renin activity. This decreases aldosterone secretion, slightly increasing serum potassium level and fluid loss.
- decreases vascular tone and blood pressure.

## Contraindications

Combination therapy with a neprilysin inhibitor (e.g., sacubitril) or within 36 hours of switching to or from sacubitril/valsartan; concurrent aliskiren use in patients with diabetes or patients with renal impairment (GFR less than 60 ml/min); hypersensitivity to captopril, other ACE inhibitors, or their components

## Interactions

### DRUGS

*adrenergic neuron-blocking drugs, beta adrenergic drugs, ganglionic blocking drugs:* Possibly increased risk of hypotension

*aliskiren in patients with diabetes, other ACE inhibitors, angiotension receptor blockers:* Increased risk of

hypotension, hyperkalemia, and renal impairment

*antacids*: Possibly impaired captopril absorption

*capsaicin*: Possibly cause or worsening of cough from ACE inhibitor

*diuretics; hypotension-producing drugs, such as*

*hydralazine*: Additive hypotensive effects

*gold*: Increased risk of nitritoid reaction, including facial flushing, hypotension, nausea, and vomiting.

*lithium*: Increased risk of lithium toxicity

*mTOR (everolimus, sirolimus, temsirolimus), neprilysin*

*inhibitor such as sacubitril*: Increased risk for angioedema

*nitrates, other vasodilators*: Possibly potentiated effects

*NSAIDs*: Decreased antihypertensive response to captopril; possible decreased renal function in elderly patients or those who are volume-depleted or already have existing impaired renal function

*potassium-containing drugs, potassium-sparing diuretics,*

*potassium supplements*: Increased risk of hyperkalemia

## **ACTIVITIES**

*alcohol use*: Additive hypotensive effects

## **FOOD**

*moderate to high potassium-containing foods*: Possibly increased risk of hyperkalemia

## **Adverse Reactions**

**CNS**: Fever

**CV**: Chest pain, **hypotension**, orthostatic hypotension, palpitations, tachycardia

**EENT**: Loss of taste

**GU:** Dysuria, impotence, **nephrotic syndrome**, nocturia, oliguria, polyuria, proteinuria, urinary frequency

**HEME:** Eosinophilia

**MS:** Arthralgia

**RESP:** Cough

**SKIN:** Photosensitivity, pruritus, rash

**Other:** **Angioedema**, **hyperkalemia**, **hyponatremia**, positive ANA titer

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm.
- Drug given during the second or third trimester reduces fetal renal function and increases fetal and neonatal morbidity and death. Resulting oligohydramnios can cause fetal lung hypoplasia and skeletal malformations.
- Drug is contraindicated in pregnancy and should not be given to a pregnant woman unless no alternative is available.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Monitor closely patient's blood pressure, especially when therapy starts and dosage increases. Also know that excessive hypotension, although rare, may occur in hypertensive patients when captopril is used in patients with heart failure or those who are undergoing renal dialysis or

in patients with salt/volume depletion (such as occurs with vigorous treatment with diuretics). Keep patient supine if hypotension occurs.

- Monitor patient's blood pressure and electrolytes routinely if patient is receiving other drugs that also affect the renin-angiotensin system because hypotension and hyperkalemia may occur.
- Monitor renal function tests for signs of nephrotic syndrome, such as proteinuria and increased BUN and serum creatinine levels. Also watch for such renal evidence as oliguria, polyuria, and urinary frequency or other signs of impaired renal function, especially in patients who are receiving other drugs that also affect the renin-angiotensin system.
- Monitor WBC regularly, as ordered, especially if patient has collagen vascular disease or renal disease.

## **PATIENT TEACHING**

- Instruct patient to take captopril 1 hour before meals.
- Tell patient to rise slowly from sitting or lying to minimize orthostatic hypotension.
- Tell patient to avoid sunlight or wear sunscreen in direct sunlight because photosensitivity may occur.
- Warn patient not to stop taking drug abruptly.
- Urge patient not to use salt substitutes that contain potassium and to consult prescriber before increasing potassium intake to avoid increasing risk of hyperkalemia.
- Urge patient to tell prescriber about signs and symptoms of infection, such as sore throat or fever.
- Advise female patient of childbearing age to notify prescriber immediately if pregnancy occurs.

## **carbamazepine**

**Carbatrol, Carnexiv, Epitol, Equetro, Novo-Carbamaz (CAN), Tegretol,**

# Tegretol-XR

## Class and Category

*Pharmacologic class:* Iminostilbene derivative

*Therapeutic class:* Analgesic, anticonvulsant

## Indications and Dosages

➤ *To treat epilepsy*

### **E.R. CAPSULES (CARBATROL, EQUETRO), E.R. TABLETS (TEGRETOL-XR)**

#### **Adults and children age 12 and over.**

*Initial:* 200 mg twice daily. Increased weekly by up to 200 mg daily, if needed, and given in divided doses twice daily.

*Maximum:* 1,600 mg daily in adults, 1,200 mg daily in children age 16 to 18, and 1,000 mg daily in children ages 12 to 15.

#### **Children ages 6 to 12. *Initial:* 100 mg twice daily.**

Increased weekly by 100 mg daily, if needed, and given in divided doses twice daily. *Maximum:* 1,000 mg daily.

## **ORAL SUSPENSION**

#### **Adults and children age 12 and over.**

*Initial:* 100 mg four times daily. Increased weekly by up to 200 mg daily, if needed, given in divided doses three times daily or four times daily. *Maximum:* 1,600 mg daily in adults, 1,200 mg daily in children age 16 and over, and 1,000 mg daily in children ages 12 to 15.

#### **Children ages 6 to 12. *Initial:* 50 mg four times daily.**

Increased weekly by 100 mg daily, if needed, given in

divided doses three times daily or four times daily.

*Maximum:* 1,000 mg daily.

**Children up to age 6.** *Initial:* 10 to 20 mg/kg/day in divided doses four times daily. *Maximum:* 35 mg/kg daily.

## **TABLETS**

**Adults and children age 12 and over.**

*Initial:* 200 mg twice daily. Increased weekly by up to 200 mg/day, if needed, given in divided doses three times daily or four times daily. *Maximum:* 1,600 mg daily in adults, 1,200 mg daily in children age 16 and over, and 1,000 mg daily in children ages 12 to 15.

**Children ages 6 to 12.** *Initial:* 100 mg twice daily.

Increased weekly by up to 100 mg daily, if needed, given in divided doses three times daily or four times daily.

*Maximum:* 1,000 mg daily.

**Children up to age 6.** *Initial:* 10 to 20 mg/kg daily in divided doses twice daily or three times daily. Increased weekly, if needed, divided and given three times daily or four times daily. *Maximum:* 35 mg/kg/day.

- *To treat generalized tonic-clonic seizures, mixed seizure patterns, or partial seizures with complex symptomatology in patients unable to receive oral therapy temporarily*

## **I.V. INFUSION (CARNEXIV)**

**Adults.** 70% of total daily oral carbamazepine dose divided equally into four 30-minute infusions with each infusion separated by 6 hr.

- *To relieve pain in trigeminal neuralgia*

## **E.R. TABLETS (TEGRETOL-XR), TABLETS**

**Adults.** *Initial:* 100 mg twice daily. Increased by up to 200 mg daily, if needed, in increments of 100 mg every 12 hr. *Maintenance:* 200 to 1200 mg daily although usual maintenance dosage is 400 to 800 mg/day. *Maximum:* 1,200 mg daily.

## **E.R. CAPSULES (CARBATROL, EQUETRO)**

**Adults.** *Day 1:* 200 mg given as 1-200 mg capsule. Increased by up to 200 mg/day, if needed, in increments of 100 mg every 12 hr. *Maintenance:* 200 mg to 1,200 mg daily with usual dosage between 400 to 800 mg daily. *Maximum:* 1,200 mg daily.

## **ORAL SUSPENSION**

**Adults.** 50 mg four times daily. Increased by up to 200 mg daily, if needed, in increments of 50 mg four times daily. *Maintenance:* 400 to 800 mg daily. *Maximum:* 1,200 mg daily.

➤ *To treat acute manic and mixed episodes in bipolar disorder*

## **E.R. CAPSULES (EQUETRO)**

**Adults.** *Initial:* 200 mg twice daily, increased as needed in 200-mg increments. *Maximum:* 1,600 mg daily.

Route	Onset	Peak	Duration
P.O. (all forms)	In 1 mo*	Unknown	Unknown

\* For anticonvulsant use; 8 to 72 hr for use in trigeminal neuralgia.

## **Mechanism of Action**

Normally, sodium moves into a neuronal cell by passing through a gated sodium channel in the cell membrane. Carbamazepine may prevent or halt seizures by closing or blocking sodium channels, as shown here, thus preventing sodium from entering the cell. Keeping sodium out of the cell may slow nerve impulse transmission, thus slowing the rate at which neurons fire.

## Contraindications

Concurrent therapy with boceprevir, delavirdine or other non-nucleoside reverse transcriptase inhibitors, or nefazodone; history of bone marrow depression; hypersensitivity to carbamazepine, tricyclic compounds, or their components; MAO inhibitor therapy within 14 days

## Interactions

### DRUGS

*acetaminophen (long-term use)*: Increased metabolism, leading to acetaminophen-induced hepatotoxicity or decreased acetaminophen effectiveness

*acetazolamide, aprepitant, cimetidine, ciprofloxacin, clarithromycin, danazol, delavirdine or other non-nucleoside reverse transcriptase inhibitors, diltiazem, erythromycin, fluconazole, fluoxetine, fluvoxamine, ibuprofen, isoniazid, itraconazole, ketoconazole, loratadine, macrolides, niacinamide, nicotinamide, olanzapine, omeprazole, oxybutynin, propoxyphene, protease inhibitors, terfenadine, ticlopidine, trazodone, troleandomycin, verapamil, voriconazole*: Increased blood carbamazepine level

*albendazole, alprazolam, amitriptyline, aprepitant, aripiprazole, boceprevir, buprenorphine, bupropion, citalopram, clonazepam, clozapine, corticosteroids, cyclosporine, dicumarol, doxycycline, eslicarbazepine, ethosuximide, everolimus, felodipine, haloperidol, imatinib, imipramine, itraconazole, lamotrigine, lapatinib, levothyroxine, methadone, mianserin, midazolam, nefazodone, nortriptyline, olanzapine, oral and other hormonal contraceptives, oxcarbazepine, paliperidone, phensuximide, phenytoin, praziquantel, protease inhibitors, risperidone, sertraline, sirolimus, tacrolimus, tadalafil, temsirolimus, theophylline, tiagabine, topiramate,*

*tramadol, trazodone, valproate, warfarin, ziprasidone, zonisamide*: Decreased blood levels of these drugs  
*aminophylline, cisplatin, doxorubicin, felbamate, fosphenytoin, loxapine, phenobarbital, phenytoin, primidone, quetiapine, rifampin, theophylline valproic acid*: Decreased blood carbamazepine level  
*cyclophosphamide*: Possibly increased cyclophosphamide toxicity  
*furosemide, hydrochlorothiazide*: Possibly increased risk of symptomatic hyponatremia  
*isoniazid*: Increased risk of carbamazepine toxicity and isoniazid hepatotoxicity  
*hormonal contraceptives*: Possibly less effectiveness of hormonal contraceptives  
*lithium*: Increased risk of CNS toxicity  
*MAO inhibitors*: Increased risk of serotonin syndrome  
*nondepolarizing neuromuscular blockers*: Possibly reduced duration or decreased effectiveness of neuromuscular blocker  
*oral anticoagulants (direct acting such as apixaban, edoxaban, dabigatran, rivaroxaban)*: Increased metabolism and decreased effectiveness of anticoagulant

## **FOODS**

*grapefruit juice*: Increased blood carbamazepine level

## **ACTIVITIES**

*alcohol use*: Increased sedative effect

## **Adverse Reactions**

**CNS**: Chills, confusion, dizziness, drowsiness, fatigue, fever, headache, **suicidal ideation**, syncope, talkativeness, unsteadiness, visual hallucinations

**CV:** Arrhythmias, including AV block; edema; heart failure; hypertension; hypotension; thromboembolism; thrombophlebitis; worsened coronary artery disease

**EENT:** Blurred vision, conjunctivitis, dry mouth, glossitis, laryngeal edema, nystagmus, oculomotor disturbances, stomatitis, tinnitus, transient diplopia

**ENDO:** Syndrome of inappropriate ADH secretion, water intoxication

**GI:** Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, elevated liver enzymes, hepatitis, jaundice, nausea, pancreatitis, vanishing bile duct syndrome, vomiting

**GU:** Acute urine retention, albuminuria, azotemia, glycosuria, impotence, oliguria, renal failure, urinary frequency

**HEME:** Acute intermittent porphyria, agranulocytosis, aplastic anemia, bone marrow depression, eosinophilia, leukocytosis, leukopenia, pancytopenia, thrombocytopenia

**MS:** Arthralgia, leg cramps, myalgia, osteoporosis

**RESP:** Pulmonary hypersensitivity (dyspnea, fever, pneumonia, or pneumonitis)

**SKIN:** Aggravation of disseminated lupus erythematosus, alopecia, altered skin pigmentation, diaphoresis, erythema multiforme, erythema nodosum, exfoliative dermatitis, nail shedding (onychomadesis), photosensitivity reactions, pruritic and erythematous rash, purpura, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

**Other:** Adenopathy, anaphylaxis, angioedema, drug reaction with eosinophilia and systemic symptoms

(DRESS) multiorgan hypersensitivity or other hypersensitivity, hypocalcemia, hypogammaglobulinemia, hyponatremia, lymphadenopathy

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.
- Drug can cause fetal harm including anomalies of various body systems such as cardiovascular malformations, congenital malformations such as spina bifida, and developmental disorders.
- Drug should not be used in pregnancy unless the benefit to the mother outweighs the potential risk to the fetus.
- Be aware that drug should not be discontinued abruptly if used to prevent major seizures in mother because of potential for status epilepticus.
- There is a higher incidence of teratogenic effects associated with the use of anticonvulsants in combination therapy so if therapy must be continued in pregnancy, monotherapy is recommended.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Avoid using carbamazepine in patients with a history of hepatic porphyria because it may prompt an acute attack. Also, be aware that the Tegretol brand suspension contains sorbitol and should not be given to a patient with fructose intolerance.

**WARNING** Note patient's ancestry. If patient has Asian ancestry, make sure he has been evaluated for the genetic allelic variant HLA-B 1502 before starting carbamazepine therapy. If patient has African-American, Chinese, European, Indian including Native American, Japanese, Korean, Latin American, Taiwanese or Thai ancestry, make sure he has been evaluated for the genetic allelic variant HLA-A 3101 before starting carbamazepine therapy. Patients positive for HLA-A 3101 or HLA-B 1502 shouldn't take carbamazepine because of the risk of serious, sometimes fatal, dermatologic reactions. The risk is between 5% and 15% in patients with these variants.

- Use carbamazepine cautiously in patients with impaired hepatic function because it's mainly metabolized in the liver. Monitor liver function tests, as directed.
- Prepare intravenous form by transferring the single dose volume to 100 ml of diluent solution such as 0.9% sodium chloride, 5% dextrose and water, or lactated Ringer's solution and mixing gently. Prepared solution may be stored up to 4 hours at room temperature or 24 hours refrigerated. Administer each infusion over 30 minutes.

**WARNING** Be aware that anaphylaxis and angioedema may occur in patients after taking the first or subsequent doses of carbamazepine. Monitor patient closely.

- Monitor patient closely for other adverse reactions because many of them are serious and some can become life-threatening, such as DRESS multiorgan hypersensitivity.
- Periodically monitor blood carbamazepine level, as ordered, to assess for therapeutic and toxic levels; a blood level of 6 to 12 mcg/ml is optimal for anticonvulsant effects.
- Monitor patient's electrolytes, especially sodium level, as ordered. Hyponatremia may occur as an adverse reaction to carbamazepine therapy, especially in the elderly and patients treated with diuretics. Assess patient regularly for signs and symptoms of hyponatremia such as confusion, difficulty concentrating, headache, memory impairment,

unsteadiness, and weakness. If present, notify prescriber and expect drug to be discontinued.

**WARNING** Monitor WBC and platelet counts monthly for first 2 months. Decreased counts may indicate bone marrow depression. Monitor patient closely, especially for agranulocytosis or aplastic anemia.

- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.
- Withdraw carbamazepine gradually to minimize risk of seizures.
- Monitor renal function in patients who are receiving carbamazepine intravenously, as they may be at greater risk of developing adverse effects on the renal system. Know that intravenous form should not be used in patients with moderate or severe renal impairment.

## PATIENT TEACHING

- Tell patient to take carbamazepine with food (except the oral suspension form, which shouldn't be taken with other liquid drugs or diluents).
- Warn patient about possible dizziness, blurred vision, and unsteadiness.
- Inform patient that coating of E.R. tablets isn't absorbed and may appear in stool.
- Advise patient not to crush or chew E.R. capsules or tablets. If he can't swallow capsules whole, have him open them and sprinkle contents on food.

**WARNING** Instruct patient to seek immediate medical care and to stop taking carbamazepine if difficulty in breathing or swallowing occurs or swelling of eyes, face, lips, or tongue develops.

- Urge patient to wear sunscreen and protective clothing to reduce photosensitivity.
- Tell patient to report bruising, fever, mouth ulcers, rash, or unusual bleeding or bruising.

- Tell female patient of childbearing age that drug decreases oral contraceptive effectiveness, and urge her to use different contraception. Because drug may cause fetal harm, tell her to notify prescriber about possible pregnancy.
- Be aware that if she becomes pregnant during therapy, urge her to enroll in the antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting information about the safety of antiepileptic drugs during pregnancy.
- Instruct caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report such tendencies to prescriber immediately.
- Advise patient to inform all prescribers of carbamazepine therapy. This is especially important if patient has had a hypersensitivity reaction to carbamazepine because about one-third of such patients will also experience hypersensitivity to oxcarbazepine.

## cariprazine

### Vraylar

## Class and Category

*Pharmacologic class:* Atypical antipsychotic

*Therapeutic class:* Antipsychotic

## Indications and Dosages

➤ *To treat schizophrenia*

### CAPSULES

**Adults. Initial:** 1.5 mg once daily, then increased to 3 mg once daily on day 2, as needed, with further increases in

1.5 mg to 3 mg increments, as needed. *Usual:* 1.5 mg to 6 mg once daily. **Maximum:** 6 mg once daily.

- *To treat acute manic or mixed episodes associated with bipolar I disorder*

## **CAPSULES**

**Adults. Initial:** 1.5 mg once daily, then increased to 3 mg once daily on day 2, with further increases in 1.5 to 3 mg increments, as needed. *Usual:* 3 mg to 6 mg once daily. *Maximum:* 6 mg once daily.

- *To treat depressive episodes associated with bipolar I disorder*

## **CAPSULES**

**Adults. Initial:** 1.5 mg once daily, increased to 3 mg once daily on day 15, as needed and tolerated. *Maximum:* 3 mg once daily.

***DOSAGE ADJUSTMENT*** For patient initiating cariprazine therapy while already taking a strong CYP3A4 inhibitor, a dose of 1.5 mg given on day 1 and day 3 with no dose on day 2. From day 4 onward, 1.5 mg daily given with possible increase to a maximum dose of 3 mg daily, as needed. For patient prescribed a strong CYP3A4 inhibitor after being on a stable dose of cariprazine, dosage reduced by half; if patient is taking 4.5 mg daily, dosage decreased to 1.5 or 3 mg daily; if patient is taking 1.5 mg, dosing frequency reduced to every other day.

## **Mechanism of Action**

May produce antipsychotic effects through partial agonist and antagonist actions. Cariprazine acts as a partial agonist at dopamine (especially D<sub>2</sub>) receptors and serotonin

(especially 5-HT<sub>1A</sub>) receptors. The drug acts as an antagonist at 5-HT<sub>2A</sub> serotonin receptor sites.

## Contraindications

Hypersensitivity to cariprazine or its components

## Interactions

### DRUGS

*CYP3A4 inducers such as carbamazepine, rifampin:*  
Possibly decreased effectiveness of cariprazine

*CYP3A4 strong inhibitors such as itraconazole, ketoconazole:* Increased exposure of cariprazine and risks of adverse reactions

## Adverse Reactions

**CNS:** Agitation, akathisia, anxiety, body temperature dysregulation, **CVA**, dystonia, dizziness, extrapyramidal symptoms, fatigue, fever, headache, insomnia, **neuroleptic malignant syndrome**, Parkinsonism, restlessness, **seizures**, somnolence, **suicidal ideation**, syncope, tardive dyskinesia

**CV:** Hyperlipidemia, hypertension, orthostatic hypotension, tachycardia

**EENT:** Blurred vision, dry mouth, nasopharyngitis, oropharyngeal pain

**ENDO:** **Diabetic ketoacidosis**, hyperglycemia (**may be extreme**), **hyperosmolar coma**

**GI:** Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, dysphagia, elevated liver enzymes, nausea, vomiting

**GU:** UTI

**HEME:** Agranulocytosis, leukopenia, neutropenia

**MS:** Arthralgia, back or extremity pain, elevated creatine phosphokinase, musculoskeletal stiffness, rhabdomyolysis

**RESP:** Cough

**SKIN:** Rash, Stevens-Johnson syndrome

**Other:** Hyponatremia, weight gain

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-961-2388 or <http://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/>.
- It is not known if drug can cause fetal harm. However, neonates exposed to antipsychotic drugs such as cariprazine during the third trimester are at risk for extrapyramidal and/or withdrawal symptoms following delivery.
- Use with caution only if the benefit to the mother outweighs the potential risk to the fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that cariprazine should not be given to patients with severe hepatic or renal impairment nor to patients receiving a CYP3A4 inducer.
- Be aware that cariprazine should not be used to treat dementia-related psychosis in the elderly because of an increased risk of death.
- Use cautiously in patients with CV disease, cerebrovascular disease, seizure disorders, or conditions that would predispose them to hypotension. Also use cautiously in elderly patients because of increased risk of serious adverse effects such as MI or stroke.
- Monitor patient for difficulty swallowing or excessive somnolence, which could predispose to accidental injury or aspiration.
- Watch patient closely for suicidal tendencies, particularly when therapy starts and with dosage changes.

**WARNING** Know that atypical antipsychotics such as cariprazine rarely may cause neuroleptic malignant syndrome, seizures, or tardive dyskinesia. Monitor patient closely throughout therapy, and take safety precautions as needed.

- Monitor patient's CBC, as ordered, because serious adverse hematologic reactions may occur, such as agranulocytosis, leukopenia, and neutropenia. Assess more often during first few months of therapy if patient has a history of drug-induced leukopenia or neutropenia or a significantly low WBC count. If abnormalities occur during therapy, watch for fever or other signs of infection, notify prescriber, and, if severe, expect drug to be discontinued.
- Monitor patient's blood glucose level, lipid levels, and weight, as ordered, because atypical antipsychotic drugs such as cariprazine may cause metabolic changes. If patient is already a diabetic, monitor blood glucose levels more closely.
- Assess patient for late-occurring adverse reactions, especially akathisia or extrapyramidal symptoms that may first appear several weeks after cariprazine therapy begins. Also be on the alert for an increase in adverse reactions after each dosage increase. If late-effect adverse reactions occur, notify prescriber, and expect dosage to be reduced or drug discontinued.

## **PATIENT TEACHING**

- Advise patient to get up slowly from a lying or sitting position during cariprazine therapy to minimize orthostatic hypotension and syncope.
- Instruct patient to avoid hazardous activities until drug's effects are known. Also, alert patient and family of increased risk for falls, especially if patient has other medical conditions or takes medication that may affect the nervous system.
- Urge patient to avoid activities that raise body temperature suddenly, such as strenuous exercise and exposure to situations that cause dehydration.
- Instruct patient to inform all prescribers of any drugs she's taking, including OTC drugs, because of risk of interactions.
- Advise female patient of childbearing age to notify prescriber if she intends to become or suspects that she is pregnant during therapy.
- Instruct diabetic patient to monitor blood glucose levels closely.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy is started and dosage changes are made.

## carisoprodol

**Soma, Vanadom**

### Class and Category

*Pharmacologic class:* Carbamate derivative

*Therapeutic class:* Skeletal muscle relaxant

*Controlled substance schedule:* IV

### Indications and Dosages

- *As adjunct to relieve acute musculoskeletal pain and stiffness*

## TABLETS

**Adults and adolescents over age 16.** 250 to 350 mg three times daily and at bedtime.

*Maximum:* 3 weeks duration of therapy.

Route	Onset	Peak	Duration
P.O.	30 min	Unknown	4–6 hr

## Mechanism of Action

Blocks interneuronal activity in descending reticular formation and spinal cord, producing muscle relaxation and sedation.

## Contraindications

History of acute, intermittent porphyria; hypersensitivity to carisoprodol, its components, or to meprobamate-related compounds

## Interactions

### DRUGS

*CNS depressants, psychotropic drugs:* Additive CNS depression

*CYP2C19 inducers such as rifampin or St. John's Wort:* Decreased carisoprodol level  
*CYP2C19 inhibitors such as fluvoxamine, omeprazole:* Increased blood carisoprodol level

### ACTIVITIES

*alcohol use:* Additive CNS depression

# Adverse Reactions

**CNS:** Agitation, ataxia, depression, dizziness, drowsiness, fever, headache, insomnia, irritability, **seizures**, somnolence, syncope, tremor, vertigo

**CV:** Orthostatic hypotension, tachycardia

**EENT:** Diplopia, transient vision loss

**GI:** Epigastric discomfort, hiccups, nausea, vomiting

**HEME:** Eosinophilia

**SKIN:** Erythema multiforme, **Erythema multiforme**, facial flushing, pruritus, rash

**Other:** Drug dependence or withdrawal

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- Breastfed infant should be monitored for drowsiness.

# Nursing Considerations

- Use carisoprodol cautiously in patients with history of drug addiction and in patients taking other CNS depressants, including alcohol.

- Know that carisoprodol therapy should last no longer than 3 weeks.
- Monitor patient closely for hypersensitivity or idiosyncratic reactions. They typically occur before the fourth dose in patients who have no previous carisoprodol exposure.
- Provide rest and other pain-relief measures.
- Expect to taper therapy as prescribed, rather than stopping it abruptly in order to avoid mild withdrawal symptoms.

## **PATIENT TEACHING**

- Tell patient to take carisoprodol with meals if GI distress occurs.
- Caution patient that drug dependence and withdrawal may occur, especially if therapy lasts a long time or patient changes dosage without consulting prescriber.
- Warn patient about possible dizziness, drowsiness, syncope, and vertigo. Discourage hazardous activities, such as driving, until effects of drug are known.
- Inform patient that abruptly stopping drug can cause headache, insomnia, nausea, and other adverse reactions.
- Instruct patient to avoid alcohol and other CNS depressants while taking drug.
- Explain that saliva, sweat, and urine may appear darker (red, brown, or black). Reassure him that this discoloration is harmless but may stain garments.
- Tell patient to store drug in a tightly capped container at room temperature.
- Tell patient not to store drug in bathroom, near kitchen sink, or in other damp places to protect it from heat and moisture.
- Advise mothers who are breastfeeding while taking carisoprodol to monitor the infant for sedation.

**carvedilol**

**Coreg**

**carvedilol phosphate**

**Coreg CR**

## **Class and Category**

*Pharmacologic class:* Nonselective beta blocker and alpha-1 blocker

*Therapeutic class:* Antihypertensive, heart failure treatment adjunct

## **Indications and Dosages**

➤ *To control hypertension*

### **TABLETS**

**Adults.** 6.25 mg twice daily with food for 7 to 14 days, if tolerated. Then dosage increased to 12.5 mg twice daily with food for 7 to 14 days, and then up to 25 mg twice daily with food, if tolerated and needed. *Maximum:* 50 mg daily with food.

### **E.R. CAPSULES**

**Adults.** *Initial:* 20 mg once daily with food in morning. After 7 to 14 days, increased to 40 mg once daily with food in morning. After another 7 to 14 days, increased to 80 mg once daily with food in morning. *Maximum:* 80 mg once daily with food in morning.

- *As adjunct to treat mild to severe chronic heart failure of ischemic or cardiomyopathic origin*

## **TABLETS**

**Adults.** 3.125 mg twice daily with food for 2 wk; then increased to 6.25, 12.5, and 25 mg twice daily with food at successive 2-wk intervals, as tolerated. *Maximum (for patients with mild to moderate heart failure):* 50 mg twice daily with food if patient weighs more than 85 kg (187 lb).

## **E.R. CAPSULES**

**Adults. Initial:** 10 mg once daily with food in morning for 2 wk. Then increased to 20 mg once daily with food in morning, as needed. Subsequent dosage increased by 20 mg every 2 wk with food in morning, as needed. *Maximum:* 80 mg once daily.

- *To reduce CV mortality after acute phase of MI in patients with left ventricular ejection fraction of 40% or less*

## **TABLETS**

**Adults.** 6.25 mg twice daily with food with food for 3 to 10 days, if tolerated. Then dosage increased to 12.5 mg twice daily for 3 to 10 days and up to 25 mg twice daily with food, if needed and tolerated.

## **E.R. CAPSULES**

**Adults. Initial:** 10 to 20 mg once daily with food in morning. After 3 to 10 days, increased to 20 to 40 mg once daily with food in morning. Increased again as needed every 3 to 10 days until reaching tolerance or target dose of 80 mg once daily with food in morning. *Maximum:* 80 mg once daily.

**DOSAGE ADJUSTMENT** For patient with fluid retention or low blood pressure or heart rate, starting dosage may be decreased, titration may be slowed, or both.

Route	Onset	Peak	Duration
P.O.	In 30 min	1.5-7 hr	Unknown

## Mechanism of Action

Reduces cardiac output and tachycardia, causes vasodilation, and decreases peripheral vascular resistance, which reduces blood pressure and cardiac workload. When given for at least 4 weeks, carvedilol reduces plasma renin activity.

## Contraindications

Bronchial asthma or related bronchospastic conditions; cardiogenic shock; decompensated heart failure that requires I.V. inotropics; history of serious hypersensitivity reactions, such as anaphylaxis, angioedema, or Stevens-Johnson syndrome; hypersensitivity to carvedilol or its components; second- or third-degree AV block, severe bradycardia, or sick sinus syndrome unless pacemaker is in place; severe hepatic impairment

## Interactions

### DRUGS

*amiodarone; other CYP2C9 inhibitors, such as fluconazole:* Increased risk of bradycardia or heart block  
*anesthetic agents that depress myocardial function (such as cyclopropane, trichloroethylene):* Increased risk of depressed myocardial function

*beta blockers, digoxin*: Increased risk of bradycardia and hypotension  
*calcium channel blockers (especially diltiazem and verapamil)*: Abnormal cardiac conduction  
*catecholamine-depleting drugs (such as MAO inhibitors, reserpine)*: Additive effects, increased risk of severe bradycardia and hypotension  
*cyclosporine, digoxin*: Increased blood levels of these drugs  
*insulin, oral antidiabetics*: Increased risk of hypoglycemia  
*potent CYP2D6 inhibitors such as fluoxetine, paroxetine, propafenone, quinidine*: Possibly increased blood carvedilol levels  
*rifampin*: Decreased significantly blood carvedilol level

## Adverse Reactions

**CNS**: Asthenia, CVA, depression, dizziness, fatigue, fever, headache, hypesthesia, hypotonia, insomnia, light-headedness, malaise, paresthesia, somnolence, syncope, vertigo

**CV**: **Angina**, **AV block**, **bradycardia**, edema, **heart failure**, hypertension, hypertriglyceridemia, orthostatic hypotension, palpitations, peripheral vascular disorder

**EENT**: Blurred vision, dry eyes, periodontitis, pharyngitis, rhinitis

**ENDO**: hyperglycemia, **hypoglycemia**

**GI**: Abdominal pain, diarrhea, elevated liver enzymes, jaundice, **melena**, nausea, vomiting

**GU**: Albuminuria, hematuria, elevated BUN and creatinine levels, impotence, incontinence, **renal insufficiency**, UTI

**HEME**: **Aplastic anemia**, **decreased PT**, **thrombocytopenia**, **unusual bleeding** or bruising

**MS:** Arthralgia, arthritis, back pain, muscle cramps

**RESP:** Dyspnea, increased cough, **interstitial pneumonitis**

**SKIN:** **Erythema multiforme**, pruritus, purpura, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, gout, **hyperkalemia**, hyperuricemia, **hyponatremia**, hypovolemia, viral infection, weight gain or loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm. However, use of beta blockers during the third trimester of pregnancy may increase the risk of neonatal bradycardia, hypoglycemia, hypotension, and respiratory depression.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use carvedilol cautiously in patients with peripheral vascular disease because it may aggravate symptoms of arterial insufficiency. In patients with diabetes mellitus it may mask signs of hypoglycemia, such as tachycardia, and may delay recovery.

- Monitor patient's blood glucose level, as ordered, during carvedilol therapy because drug may alter blood glucose level.

**WARNING** Avoid stopping drug abruptly in patients with hyperthyroidism because thyroid storm may occur, and in patients with angina because it may worsen or MI may occur.

- Know that if patient has heart failure, expect to also give digoxin, a diuretic, and an ACE inhibitor.
- Be aware that chronic beta blocker therapy such as carvedilol is not routinely withheld prior to major surgery because the benefits outweigh the risks associated with its use with general anesthesia and surgical procedures.

## **PATIENT TEACHING**

- Instruct patient to swallow extended-release capsules whole. If swallowing capsules is difficult, tell patient he may open capsule and sprinkle beads on a spoonful of cold applesauce and then eat the applesauce immediately without chewing.
- Warn patient that drug may cause dizziness, light-headedness, and orthostatic hypotension; advise him to take precautions.
- Tell patient with heart failure to notify prescriber if he gains 5 lb or more in 2 days or if shortness of breath increases, which may signal worsening heart failure.
- Alert patient with diabetes to monitor his glycemic control closely because drug may increase blood glucose level or mask symptoms of hypoglycemia.
- Emphasize the need to seek emergency care if patient develops hives or swelling of the face, lips, tongue, or throat that causes trouble swallowing or breathing.
- Advise patient to notify ophthalmologist of carvedilol therapy because if cataract surgery is required, modifications of the surgical technique may be necessary.
- Tell patient to notify prescriber of all medications taken, including over-the-counter preparations, before using them.

- Tell women of childbearing age to inform prescriber if pregnancy is known or suspected, as safety in pregnancy is unknown. Also, tell mothers wishing to breastfeed to discuss this decision with prescriber before doing so.

## casprofungin acetate

### Cancidas

## Class and Category

*Pharmacologic class:* Echinocandins

*Therapeutic class:* Antifungal

## Indications and Dosages

- *To treat invasive aspergillosis in patients refractory to or intolerant of other therapies; to treat candidemia and candidal infections in intra-abdominal abscesses, peritonitis, and pleural space infections*

### I.V. INFUSION

**Adults.** *Initial:* 70 mg infused over 1 hr on day 1, followed by 50 mg infused over 1 hr once daily. *Maximum:* 70 mg once daily.

**Children ages 3 months to 17 years.**

*Initial:* 70 mg/m<sup>2</sup> infused over 1 hr on day 1, followed by 50 mg/m<sup>2</sup> infused over 1 hr once daily and increased to 70 mg/m<sup>2</sup> once daily and given over 1 hr, if needed and tolerated. *Maximum:* 70 mg once daily regardless of dose calculated based on patient's body surface area.

- *To treat presumed fungal infections in febrile, neutropenic patients*

## **I.V. INFUSION**

**Adults.** *Initial:* 70 mg infused over 1 hr on day 1, followed by 50 mg infused over 1 hr once daily for at least 14 days, including at least 7 days after neutropenia and symptoms have resolved. Increased to 70 mg infused over 1 hr once daily as needed. *Maximum:* 70 mg once daily.

**Children ages 3 months to 17 years.**

*Initial:* 70 mg/m<sup>2</sup> infused over 1 hr on day 1, followed by 50 mg/m<sup>2</sup> infused over 1 hr once daily for at least 14 days, including at least 7 days after neutropenia and symptoms have resolved. *Maximum:* 70 mg once daily regardless of dose calculated based on patient's body surface area.

- *To treat esophageal candidiasis*

## **I.V. INFUSION**

**Adults.** 50 mg infused over 1 hr once daily for 7 to 14 days after symptoms have resolved.

**Children ages 3 months to 17 years.**

*Initial:* 70 mg/m<sup>2</sup> infused over 1 hr on day 1, followed by 50 mg/m<sup>2</sup> infused over 1 hr once daily. *Maximum:* 70 mg once daily regardless of dose calculated based on patient's body surface area.

***DOSAGE ADJUSTMENT*** For patients with moderate hepatic insufficiency, dosage reduced to 35 mg daily after initial 70-mg loading dose, if a loading dose is required. For patients receiving carbamazepine, dexamethasone, efavirenz, nevirapine, phenytoin, or rifampin, dosage may be increased to 70 mg once daily for adults and 70 mg/m<sup>2</sup> once daily for children (not to exceed 70 mg daily).

# Incompatibilities

Don't mix or infuse with other drugs. Don't admix with diluents that contain dextrose.

# Contraindications

Hypersensitivity to caspofungin acetate or its components

# Interactions

## DRUGS

*carbamazepine, dexamethasone, efavirenz, nelfinavir, nevirapine, phenytoin, rifampin*: Possibly decreased blood caspofungin level

*cyclosporine*: Transient increases in ALT and AST levels

*tacrolimus*: Possibly decreased blood tacrolimus level

# Adverse Reactions

**CNS:** Asthenia, anxiety, chills, confusion, depression, dizziness, fatigue, fever, headache, insomnia, paresthesia, **seizures**, somnolence, tremor, warmth sensation

**CV:** Edema, hypertension, **hypotension**, phlebitis, tachycardia, thrombophlebitis

**EENT:** Epistaxis, mucosal inflammation, **stridor**

**ENDO:** Hyperglycemia

**GI:** Abdominal distention or pain, anorexia, constipation, diarrhea, dyspepsia, elevated liver enzymes, **hepatic dysfunction or necrosis**, hepatomegaly, hyperbilirubinemia, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Elevated BUN or serum creatinine level, hematuria, proteinuria, **renal failure or insufficiency**, UTI

**HEME:** Decreased hemoglobin and hematocrit

**MS:** Arthralgia, back or extremity pain, myalgia

**RESP:** **Bronchospasm**, cough, crackles, dyspnea, **hypoxia**, pleural effusion, pneumonia, **respiratory failure**, tachypnea

**SKIN:** Diaphoresis, erythema, **erythema multiforme**, flushing, petechiae, pruritus, rash, sensation of warmth, skin exfoliation, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **bacteremia**, **decreased serum bicarbonate level**, elevated gamma-glutamyltransferase level, **hypercalcemia**, **hyperkalemia**, hyperphosphatemia, **hypokalemia**, **hypomagnesemia**, infusion-site reaction, **sepsis**, **septic shock**

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm based on animal studies.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cautiously in patients with a history of allergic skin reactions because caspofungin may cause serious skin reactions such as Stevens-Johnson syndrome and toxic epidermal necrolysis, which can be life-threatening. Prepare a 70-mg loading dose by letting vial reach room temperature. Reconstitute by adding 10.5 ml normal saline solution to vial. Dilute for administration by transferring 10 ml of reconstituted drug to 250 ml normal saline solution.
- Prepare a 70-mg loading dose from two 50-mg vials by adding 10.5 ml normal saline solution to each vial; then transfer 14 ml of prepared solution to 250 ml normal saline solution.
- Prepare a daily 50-mg infusion by letting vial reach room temperature. Reconstitute by adding 10.5 ml normal saline solution to vial. Dilute for administration by transferring only 10 ml of reconstituted drug to 250 ml normal saline solution.
- Prepare a daily 50-mg infusion at reduced volume by adding 10 ml of reconstituted drug to 100 ml normal saline solution.

## Mechanism of Action

Caspofungin acetate interferes with fungal cell membrane synthesis by inhibiting the synthesis of  $\beta$  (1, 3)-D-glucan. A polypeptide,  $\beta$  (1, 3)-D-glucan is the essential component of the fungal cell membrane that makes it rigid and protective. Without it, fungal cells rupture and die. This mechanism of action is most effective against susceptible filamentous fungi, such as *Aspergillus*.

- Prepare a 35-mg daily dose for patient with moderate hepatic insufficiency, by reconstituting 50-mg vial with 10.5 ml normal saline solution. To dilute, transfer only 7 ml of reconstituted drug to 250 ml normal saline solution or, if needed, to 100 ml normal saline solution.
- Mix powder gently to obtain clear solution. Don't use if solution is cloudy or contains precipitate. Discard unused solution after 24 hours.
- Infuse drug slowly over about 1 hour.
- Watch for flushed skin, and assess patient often for unexplained temperature elevation.
- Monitor patient for possible histamine-mediated adverse reactions such as angioedema, bronchospasm, facial swelling, pruritus, rash, or warmth sensation. Report these symptoms immediately and expect caspofungin therapy to be discontinued.

**WARNING** Assess for airway patency if patient develops excessive facial edema or respiratory stridor. Provide emergency airway management if complete obstruction occurs.

- Monitor patient's liver function test results, as ordered, and report abnormalities.

## PATIENT TEACHING

- Urge patient to notify prescriber immediately if he has difficulty talking, swallowing, or breathing during drug administration.

# cefaclor

## Ceclor (CAN)

## Class and Category

*Pharmacologic class:* Second-generation cephalosporin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat otitis media caused by Haemophilus influenzae, staphylococci, Streptococcus pneumoniae, or Streptococcus pyogenes; lower respiratory tract infections, including pneumonia caused by H. influenzae, S. pneumoniae, or S. pyogenes; pharyngitis and tonsillitis caused by S. pyogenes; UTI, including cystitis and pyelonephritis, caused by Escherichia coli,*

*Klebsiella species, Proteus mirabilis, or coagulase-negative staphylococci; and skin and soft-tissue infections caused by S. pyogenes or Staphylococcus aureus*

## **CAPSULES**

**Adults and adolescents.** 250 mg every 8 hr. For severe infections, such as pneumonia, or those caused by less susceptible organisms, 500 mg every 8 hr. *Maximum:* 4 g daily.

## **CHEWABLE TABLETS, ORAL SUSPENSION**

**Adults and adolescents.** 250 mg every 8 hr. For severe infections, such as pneumonia, or those caused by less susceptible organisms, 500 mg every 8 hr. *Maximum:* 4 g daily.

**Children.** 20 mg/kg daily in divided doses every 8 hr. For serious infections, such as otitis media, and infections caused by less susceptible organisms, 40 mg/kg daily in divided doses every 8 hr. For otitis media and pharyngitis, total daily dosage divided and given every 12 hr, if needed. *Maximum:* 1 g daily.

- *To treat acute bacterial infection in chronic bronchitis or secondary bacterial infection in acute bronchitis caused by H. influenzae, Moraxella catarrhalis, or S. pneumoniae*

## **E.R. TABLETS**

**Adults and adolescents age 16 and over.** 500 mg with food every 12 hr for 7 days.

- *To treat pharyngitis and tonsillitis caused by S. pyogenes*

## **E.R. TABLETS**

**Adults and adolescents age 16 and over.** 750 mg with food every 12 hr for 10 days.

- *To treat uncomplicated skin and soft-tissue infections caused by S. aureus*

## **E.R. TABLETS**

**Adults and adolescents age 16 and over.** 375 mg with food every 12 hr for 7 to 10 days.

## **Mechanism of Action**

Interferes with bacterial cell wall synthesis by inhibiting cross-linking of peptidoglycan strands, which stiffen cell membranes. As a result, bacterial cells rupture.

## **Contraindications**

Hypersensitivity to cefaclor, other cephalosporins, or their components

## **Interactions**

### **DRUGS**

*aminoglycosides, loop diuretics:* Increased risk of nephrotoxicity

*antacids:* Decreased blood cefaclor level (E.R. tablets)

*oral anticoagulants:* Increased anticoagulation

*probenecid:* Increased serum cefaclor levels

## **Adverse Reactions**

**CNS:** Chills, fever, headache, **seizures**

**CV:** Edema

**EENT:** Hearing loss, oral candidiasis

**GI:** Abdominal cramps, diarrhea, elevated liver enzymes, **hepatic failure**, hepatomegaly, nausea, **pseudomembranous colitis**, vomiting

**GU:** Elevated BUN level, **nephrotoxicity**, **renal failure**, vaginal candidiasis

**HEME:** Eosinophilia, **hemolytic anemia**, **hypoprothrombinemia**, **neutropenia**, **thrombocytopenia**, **unusual bleeding**

**MS:** Arthralgia

**RESP:** Dyspnea

**SKIN:** Ecchymosis, erythema, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**

**Other:** **Anaphylaxis**, superinfection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Use cefaclor cautiously in patients with impaired renal function or a history of GI disease, particularly colitis, and in patients who are hypersensitive to penicillin; about 10% of them have cross-sensitivity.
- Obtain culture and sensitivity test results, if possible and as ordered, before giving drug.
- Monitor BUN and serum creatinine levels for early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Be aware that an allergic reaction may occur a few days after therapy starts.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Assess patient for superinfection: cough or sputum changes, diarrhea, drainage, fever, malaise, pain, perineal itching, rash, redness, and swelling.

## PATIENT TEACHING

- Instruct patient to complete the prescribed course of therapy, even if he feels better.
- Tell patient to swallow E.R. tablets whole and not to break, chew, or crush them.
- Advise patient to take E.R. tablets with food to enhance absorption.
- Instruct patient to take capsules or E.R. tablets with a full glass of water.
- Tell patient to shake oral suspension well before measuring and to use a calibrated measuring device to ensure accurate dose.
- Tell patient to refrigerate oral suspension and to discard unused portion after 14 days.
- Instruct patient to report severe diarrhea to prescriber immediately.
- Explain that buttermilk and yogurt protect intestinal flora and decrease diarrhea.
- Urge patient to report evidence of superinfection.

# cefazolin sodium

**Ancef, Kefzol**

## Class and Category

*Pharmacologic class:* First-generation cephalosporin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat respiratory tract infections caused by Haemophilus influenzae, Klebsiella species, Staphylococcus aureus, Streptococcus pneumoniae, or group A beta-hemolytic streptococci; skin and soft-tissue infections caused by S. aureus, group A beta-hemolytic streptococci, or other strains of streptococci; biliary or urinary tract infections caused by Escherichia coli, Proteus mirabilis, S. aureus, or various strains of streptococci; bone and joint infections caused by S. aureus; genital infections, such as epididymitis and prostatitis, caused by E. coli, Klebsiella species, P. mirabilis, and some strains of enterococci; septicemia caused by E. coli, Klebsiella species, P. mirabilis S. aureus, and S. pneumoniae; and endocarditis caused by S. aureus or group A beta-hemolytic streptococci*

## I.V. INFUSION, I.V. OR I.M. INJECTION

**Adults.** For mild infections caused by susceptible gram-positive cocci, 250 to 500 mg every 8 hr; for moderate to

severe infections, 500 to 1,000 mg every 6 to 8 hr; and for severe life-threatening infections, 1,000 to 1,500 mg every 6 hr. I.V. injection given as a bolus slowly over 3 to 5 min. I.V. infusion given over 30 min. *Maximum:* 6 g daily.

**Children.** For mild to moderate infections, 25 to 50 mg/kg daily divided equally and given three times daily or four times daily; for severe infections, 100 mg/kg daily divided equally and given three times daily or four times daily. I.V. injection given as a bolus slowly over 3 to 5 min. I.V. infusion given over 30 min.

➤ *To treat pneumococcal pneumonia*

### **I.V. INFUSION, I.V. OR I.M. INJECTION**

**Adults.** 500 mg every 12 hr. I.V. injection given as bolus slowly over 3 to 5 min. I.V. infusion given over 30 min.

➤ *To treat acute uncomplicated UTI caused by E. coli, Klebsiella species, or P. mirabilis, and some strains of Enterobacter and Enterococcus*

### **I.V. INFUSION, I.V. OR I.M. INJECTION**

**Adults.** 1 g every 12 hr. I.V. injection given as a bolus slowly over 3 to 5 min. I.V. infusion given over 30 min.

➤ *To provide surgical prophylaxis*

### **I.V. INFUSION, I.V. OR I.M. INJECTION**

**Adults.** 1 g 30 to 60 min before surgery; 0.5 to 1 g during surgery if it lasts 2 hr or longer; 0.5 to 1 g every 6 to 8 hr for 24 hr after surgery. I.V. injection given as a bolus slowly over 3 to 5 min. I.V. infusion given over 30 min.

***DOSAGE ADJUSTMENT*** After initial loading dose appropriate to infection's severity, dosage interval restricted to at least 8 hr for adults with creatinine clearance of 35 to 54 ml/min; dosage reduced by 50% and given every 12 hr for adults

with creatinine clearance of 11 to 34 ml/min; and dosage reduced by 50% and given every 18 to 24 hr for adults with creatinine clearance of 10 ml/min or less. Dosage reduced to 60% and given every 12 hr for children with creatinine clearance of 40 to 70 ml/min; dosage reduced to 25% and given every 12 hr for children with creatinine clearance of 20 to 40 ml/min; and dosage reduced to 10% and given every 24 hr for children with creatinine clearance of 5 to 20 ml/min.

## **Mechanism of Action**

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

## **Incompatibilities**

To prevent mutual inactivation, don't mix cefazolin with aminoglycosides. Also avoid mixing cefazolin with other drugs, including pentamidine isethionate.

## **Contraindications**

Hypersensitivity to cefazolin, other cephalosporins or their components

## **Interactions**

### **DRUGS**

*aminoglycosides, loop diuretics*: Additive nephrotoxicity  
*probenecid*: Increased and prolonged blood cefazolin level

# Adverse Reactions

**CNS:** Chills, fever, headache, **seizures**

**CV:** Edema

**EENT:** Hearing loss, oral candidiasis

**GI:** Abdominal cramps, diarrhea, elevated liver enzymes, **hepatic failure**, **hepatitis**, hepatomegaly, nausea, **pseudomembranous colitis**, vomiting

**GU:** Elevated BUN and serum creatinine levels, **nephrotoxicity**, **renal failure**, vaginal candidiasis

**HEME:** Eosinophilia, **hemolytic anemia**, **hypoprothrombinemia**, **neutropenia**, **thrombocytopenia**, **unusual bleeding**

**MS:** Arthralgia

**RESP:** Dyspnea

**SKIN:** Ecchymosis, erythema, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**

**Other:** **Anaphylaxis**; injection-site pain, redness, and swelling; superinfection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cefazolin cautiously in patients with impaired renal function or a history of GI disease, particularly colitis. Also use cautiously in patients hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- Obtain culture and sensitivity test results, if possible and as ordered, before giving drug.

**WARNING** Know that to prevent unintentional overdose, the 2-g dose container of cefazolin for injection USP and dextrose injection USP shouldn't be used in children who require less than the full adult dose. Instead, use only the 1-g container of cefazolin for injection USP and dextrose injection USP for children when the individual dose is the entire contents of the 1-g container and not any fraction of it.

- Reconstitute 500-mg drug vial with 2 ml of sterile water for injection (or 1-g vial with 2.5 ml). Shake well until dissolved.
- For direct I.V. injection, further dilute reconstituted solution with at least 5 ml sterile water for injection. Inject slowly over 3 to 5 minutes through tubing of a flowing compatible I.V. solution.
- For intermittent I.V. infusion, reconstitute 500 to 1,000 mg in 50 to 100 ml normal saline solution, D<sub>5</sub>W, D<sub>10</sub>W, dextrose 5% in lactated Ringer's solution, dextrose 5% in quarter-normal (0.2) saline solution, dextrose 5% in half-normal (0.45) saline solution, dextrose 5% in normal saline solution, lactated Ringer's injection, 5% or 10% invert sugar in sterile water for injection, 5% sodium bicarbonate (Ancef), or Ringer's injection.
- Administer I.M. injection deep into large muscle mass, such as the gluteus maximus.
- Store reconstituted drug up to 24 hours at room temperature or 10 days refrigerated.

- Monitor I.V. site for irritation, phlebitis, and extravasation.
- Monitor BUN and serum creatinine for early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Be aware that an allergic reaction may occur a few days after therapy starts.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Watch for evidence of superinfection: cough, diarrhea, drainage, fever, malaise, pain, perineal itching, rash, redness, swelling.
- Assess for arthralgia, bleeding, ecchymosis, and pharyngitis; they may indicate a blood dyscrasia.

## PATIENT TEACHING

- Instruct patient to complete the prescribed course of therapy.
- Reassure patient that I.M. injection doesn't typically cause pain.
- Tell patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

**cefdinir**

## Class and Category

*Pharmacologic class:* Third-generation cephalosporin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat community-acquired pneumonia caused by Haemophilus influenzae (including beta-lactamase-*

*producing strains), H. parainfluenzae (including beta-lactamase-producing strains), Moraxella catarrhalis (including beta-lactamase-producing strains), and Streptococcus pneumoniae (penicillin-susceptible strains only)*

## **CAPSULES**

**Adults and adolescents.** 300 mg every 12 hr for 10 days. *Maximum:* 600 mg daily.

- *To treat pharyngitis or tonsillitis caused by Streptococcus pyogenes and acute exacerbations of chronic bronchitis caused by H. influenzae (including beta-lactamase-producing strains), H. parainfluenzae (including beta-lactamase-producing strains), S. pneumoniae (penicillin-susceptible strains only), and M. catarrhalis (including beta-lactamase-producing strains)*

## **CAPSULES**

**Adults and adolescents.** 300 mg every 12 hr for 5 to 10 days or 600 mg every 24 hr for 10 days. *Maximum:* 600 mg daily.

## **ORAL SUSPENSION**

**Children ages 6 months to 12 years.** 7 mg/kg every 12 hr for 5 to 10 days or 14 mg/kg every 24 hr for 10 days (for pharyngitis or tonsillitis).

- *To treat acute maxillary sinusitis caused by H. influenzae (including beta-lactamase-producing strains), S. pneumoniae (penicillin-susceptible strains only), and M. catarrhalis (including beta-lactamase-producing strains)*

## CAPSULES

**Adults and adolescents.** 300 mg every 12 hr or 600 mg every 24 hr for 10 days. *Maximum:* 600 mg daily.

## ORAL SUSPENSION

**Children ages 6 months to 12 years.** 7 mg/kg every 12 hr or 14 mg/kg every 24 hr for 10 days.

- *To treat uncomplicated skin and soft-tissue infections caused by Staphylococcus aureus (including beta-lactamase-producing strains) and S. pyogenes*

## CAPSULES

**Adults and adolescents.** 300 mg every 12 hr for 10 days. *Maximum:* 600 mg daily.

## ORAL SUSPENSION

**Children ages 6 months to 12 years.** 7 mg/kg every 12 hr for 10 days.

- *To treat acute bacterial otitis media caused by H. influenzae (including beta-lactamase-producing strains), S. pneumoniae (penicillin-susceptible strains only), and M. catarrhalis (including beta-lactamase-producing strains)*

## ORAL SUSPENSION

**Children ages 6 months to 12 years.** 7 mg/kg every 12 hr for 5 to 10 days or 14 mg/kg every 24 hr for 10 days.

***DOSAGE ADJUSTMENT*** For adults with creatinine clearance less than 30 ml/min, dosage not to exceed 300 mg daily; for children with creatinine clearance less than 30 ml/min, dosage not to exceed 7 mg/kg (up to 300 mg) daily. For patients undergoing intermittent hemodialysis, dosage is

300 mg or 7 mg/kg every other day, beginning at the end of each hemodialysis session, as prescribed.

## **Mechanism of Action**

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptido-glycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die. Because cefdinir is not degraded by some bacterial beta-lactamase enzymes, it's effective against many organisms that are resistant to both penicillins and some cephalosporins.

## **Contraindications**

Hypersensitivity to cefdinir, other cephalosporins, or their components

## **Interactions**

### **DRUGS**

*antacids that contain aluminum or magnesium:* Decreased cefdinir absorption if given within 2 hours of antacid

*iron salts:* Reduced cefdinir absorption if given within 2 hours of iron

*probenecid:* Increased blood level and prolonged half-life of cefdinir

## **Adverse Reactions**

**CNS:** Asthenia, dizziness, drowsiness, headache, insomnia, somnolence

**EENT:** Dry mouth, pharyngitis, rhinitis

**GI:** Abdominal pain, anorexia, constipation, diarrhea, flatulence, indigestion, nausea, **pseudomembranous colitis**, stool discoloration, vomiting

**GU:** Leukorrhea, vaginal candidiasis, vaginitis

**HEME:** **Leukopenia**

**SKIN:** Pruritus, rash

**Other:** **Anaphylaxis**, serum sickness-like reaction

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Reconstitute cefdinir powder for oral suspension by tapping bottle to loosen powder, and then dilute with water to 125 mg/5 ml. Shake well before each use. Discard any unused portion after 10 days. Keep suspension bottle tightly closed, and store it at room temperature.
- Give antacids that contain aluminum or magnesium and iron salts at least 2 hours before or after cefdinir because they may interfere with cefdinir absorption.
- Monitor patient allergic to penicillin for evidence of hypersensitivity reaction, from a mild rash to fatal anaphylaxis, because cross-sensitivity can occur.

- Monitor patient with a chronic GI condition, such as colitis, for signs and symptoms of a drug-related exacerbation.
- Know that because all cephalosporins have the potential to cause bleeding, monitor elderly patients and patients with a preexisting coagulopathy, including vitamin K deficiency, for elevated PT or APTT.
- Monitor patient closely for diarrhea, which may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold cefdinir and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- Assess for other evidence of superinfection, including perineal itching; loose, foul-smelling stools; and vaginal drainage.

## PATIENT TEACHING

- Advise patient taking cefdinir oral suspension to shake bottle well before use and to use a liquid-measuring device to ensure accurate dose.
- Inform patient that tablet coating may cause stools to become a reddish color.
- Instruct patient to complete entire course of therapy, even if he feels better.
- Advise patient to take iron salts and aluminum- or magnesium-containing antacids at least 2 hours before or after taking cefdinir.
- Inform patient with history of colitis that cefdinir may worsen it; urge him to notify prescriber promptly if symptoms develop.
- Inform patient with diabetes mellitus that oral suspension contains 2.86 g of sucrose per teaspoon; advise him to monitor his blood glucose levels as appropriate.
- Teach patient to recognize and report evidence of superinfection, such as perineal itching; loose, foul-smelling stools; and vaginal drainage.
- Inform patient that buttermilk and yogurt can help prevent superinfection and may decrease diarrhea.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.

# cefditoren pivoxil

**Spectracef**

## Class and Category

*Pharmacologic class:* Third-generation cephalosporin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat mild to moderate acute bacterial exacerbation of chronic bronchitis or community-acquired pneumonia caused by Haemophilus influenzae (including beta-lactamase-producing strains), Haemophilus parainfluenzae (including beta-lactamase-producing strains), Streptococcus pneumoniae (penicillin-susceptible strains), or Moraxella catarrhalis (including beta-lactamase-producing strains)*

### **TABLETS**

**Adults and children age 12 and over.** 400 mg twice daily for 10 days or for 14 days for community-acquired pneumonia.

- *To treat mild to moderate pharyngitis and tonsillitis caused by Streptococcus pyogenes*

### **TABLETS**

**Adults and children age 12 and over.** 200 mg twice daily for 10 days.

- *To treat mild to moderate uncomplicated skin and soft-tissue infections caused by Staphylococcus aureus (including beta-lactamase-producing strains) or S. pyogenes*

## **TABLETS**

**Adults and children age 12 and over.** 200 mg twice daily for 10 days.

***DOSAGE ADJUSTMENT*** For patient with a creatinine clearance of 30 to 49 ml/min, maximum dosage reduced to 200 mg twice daily. For patient with a creatinine clearance less than 30 ml/min, maximum dosage reduced to 200 mg daily.

## **Mechanism of Action**

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die. This mechanism of action is most effective against bacteria that divide rapidly, including many gram-positive and gram-negative bacteria. Cefditoren isn't inactivated by beta lactamase produced by some bacteria.

## **Contraindications**

Carnitine deficiency or inborn metabolic disorder that causes it; hypersensitivity to cefditoren, other cephalosporins or their components, or to milk

## **Interactions**

## **DRUGS**

*aluminum- and magnesium-containing antacids, H<sub>2</sub>-receptor antagonists*: Reduced cefditoren absorption  
*H<sub>2</sub>-receptor antagonists such as famotidine*: Possibly reduced absorption of cefditoren  
*probenecid*: Increased and prolonged blood cefditoren level

## **FOODS**

*any food*: Increased cefditoren absorption

## **Adverse Reactions**

**CNS**: Headache, hyperactivity, hypertonia, **seizures**

**GI**: Abdominal pain, diarrhea, dyspepsia, **hepatic dysfunction**, nausea, **pseudomembranous colitis**, vomiting

**GU**: **Acute renal failure, renal dysfunction, toxic nephropathy**

**HEME**: **Aplastic anemia, hemolytic anemia, hemorrhage, thrombocytopenia**

**MS**: Arthralgia

**RESP**: Pneumonia

**SKIN**: **Erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis**

**Other**: Allergic reaction, **anaphylaxis**, carnitine deficiency, drug fever, serum sickness-like reaction, superinfection

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Be aware that before starting cefditoren therapy, determine if patient is hypersensitive to milk protein because cefditoren contains sodium caseinate, a milk protein. Drug should not be given to patient with this hypersensitivity. Also determine if patient has had a hypersensitivity reaction to cefditoren or other cephalosporins (because drug is contraindicated in these patients) or to penicillin (because cross-sensitivity has occurred in about 10% of such patients).

- Know that cefditoren shouldn't be used for prolonged treatment because of the risk of carnitine deficiency.
- Obtain culture and sensitivity test results before giving cefditoren, if possible and as ordered.
- Assess patient for evidence of *Clostridium difficile* infection and pseudomembranous colitis, such as profuse, watery diarrhea. For mild cases, expect to discontinue cefditoren. For moderate to severe cases, expect to also give fluids and electrolytes, protein supplementation, and an antibacterial drug effective against *C. difficile*.
- Monitor patient for an allergic reaction. If an allergic reaction occurs, expect to discontinue drug, as prescribed. For serious acute hypersensitivity reactions, expect to also give antihistamines, corticosteroids, epinephrine, I.V. fluids, oxygen, and vasopressors, as prescribed.

- Monitor BUN and serum creatinine levels to detect early signs of renal dysfunction. Also monitor fluid intake and output.
- Watch for a decreased PT, as ordered, in at-risk patients, such as those with renal or hepatic impairment, those with a poor nutritional state, and those receiving anticoagulant or prolonged antibiotic therapy. Notify prescriber if a decrease occurs, and give vitamin K as ordered.

## PATIENT TEACHING

- Urge patient to complete prescribed course of therapy.
- Instruct patient to take cefditoren with meals to enhance drug absorption.
- Advise patient not to take cefditoren with aluminum- or magnesium-containing antacids or other drugs used to reduce stomach acids because these drugs may interfere with cefditoren absorption.
- Explain that buttermilk and yogurt help maintain normal intestinal flora and can decrease diarrhea during therapy.
- Instruct patient to report severe diarrhea to prescriber immediately.

## cefepime hydrochloride

### Maxipime

## Class and Category

*Pharmacologic class:* Fourth-generation cephalosporin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat mild to moderate UTI caused by Escherichia coli, Klebsiella pneumoniae, or Proteus mirabilis*

## **I.V. INFUSION, I.M. INJECTION (ONLY FOR UTI CAUSED BY E. COLI)**

**Adults and children age 16 and over.** 500 to 1,000 mg every 12 hr for 7 to 10 days. I.V. infusion given over 30 min.

**Children ages 2 months to 16 years weighing up to 40 kg (88 lb).** 50 mg/kg/dose every 12 hr for 7 to 10 days. I.V. infusion given over 30 min.

*Maximum:* Not to exceed adult dose.

- *To treat severe UTI caused by E. coli or K. pneumoniae, uncomplicated skin and soft-tissue infections caused by Staphylococcus aureus or Streptococcus pyogenes*

## **I.V. INFUSION**

**Adults and children age 16 and over.** 2 g given over 30 min every 12 hr for 10 days.

## **I.V. INFUSION**

**Children ages 2 months to 16 years weighing up to 40 kg (88 lb).** 50 mg/kg/dose given over 30 min every 12 hr for 10 days. *Maximum:* Not to exceed adult dose.

- *To treat moderate to severe pneumonia caused by Enterobacter species, K. pneumoniae, Pseudomonas aeruginosa, or Streptococcus pneumoniae*

## **I.V. INFUSION**

**Adults and children age 16 and over.** 2 g given over 30 min every 8 hr if caused by *P. aeruginosa* or 1 to 2 g every 12 hr for other infections for 10 days.

- *To treat moderate to severe pneumonia caused by P. aeruginosa*

## I.V. INFUSION

**Children ages 2 months to 16 years weighing up to 40 kg (88 lb).** 50 mg/kg/dose infused over 30 min every 8 hr for 10 days. *Maximum:* Not to exceed adult dose.

- *To treat febrile neutropenia*

## I.V. INFUSION

**Adults and children age 16 and over.** 2 g infused over 30 min every 8 hr for 7 days or until neutropenia resolves. **Children ages 2 months to 16 years weighing up to 40 kg (88 lb).** 50 mg/kg/dose infused over 30 min every 8 hr for 7 days or until neutropenia resolves. *Maximum:* Not to exceed adult dose.

- *To treat complicated intra-abdominal infections (together with metronidazole) caused by Bacteroides fragilis, E. coli, Enterobacter species, K. pneumoniae, P. aeruginosa, or viridans group streptococci*

## I.V. INFUSION

**Adults and children age 16 and over.** 2 g infused over 30 min every 8 to 12 hr for 7 to 10 days.

***DOSAGE ADJUSTMENT*** For adult patient with creatinine clearance between 30 and 60 ml/min, dosing interval increased to every 24 hr if dosing interval had been every 12 hr, and dosing interval increased to every 12 hr if dosing interval had been every 8 hr. For adult patient with creatinine clearance between 11 and 29 ml/min, dosage decreased to 500 mg every 24 hr if dosage had been 1 g every 24 hr; dosage decreased to 1 g every 24 hr if dosage had been 2 g every 24 hr; and dosing interval decreased to 24 hr if dosing interval had been every 12 hr while maintaining a dosage of 2 g. For adult patient with creatinine clearance less than 11 ml/min, dosage decreased

to 250 mg every 24 hr if dosage had been 500 mg every 24 hr; dosage decreased to 500 mg every 24 hr if dosage had been 1 g every 24 hr; and dosage decreased to 1 g every 24 hr if dosage had been 2 g every 24 hr. For adult patient on continuous abdominal peritoneal dialysis or hemodialysis, dosage interval and dosage further altered. For pediatric patient, dosage decreased and dosage interval increased in similar proportion as adults.

## **Mechanism of Action**

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

## **Incompatibilities**

Don't add cefepime to solutions that contain ampicillin in a concentration of more than 40 mg/ml. Don't add drug to solutions that contain aminophylline, gentamycin, metronidazole, netilmicin sulfate, tobramycin, or vancomycin.

## **Contraindications**

Hypersensitivity to cefepime, other beta-lactam antibiotics, other cephalosporins, penicillins, or their components

## **Interactions**

### **DRUGS**

*aminoglycosides*: Increased risk of nephrotoxicity and ototoxicity

*potent diuretics such as furosemide*: Increased risk of nephrotoxicity

## Adverse Reactions

**CNS:** Aphasia, chills, **coma**, confusion, **encephalopathy**, fever, hallucinations, headache, myoclonus, **neurotoxicity**, **nonconvulsive status epilepticus**, **seizures**, stupor

**CV:** Edema

**EENT:** Hearing loss, oral candidiasis

**GI:** Abdominal cramps, diarrhea, elevated liver enzymes, **hepatic failure**, hepatomegaly, nausea, **pseudomembranous colitis**, vomiting

**GU:** Elevated BUN level, **nephrotoxicity**, **renal failure**, vaginal candidiasis

**HEME:** **Agranulocytosis**, eosinophilia, **hemolytic anemia**, **hypoprothrombinemia**, **leukopenia**, **neutropenia**, positive direct Coombs' tests, **thrombocytopenia**, **unusual bleeding**

**MS:** Arthralgia

**RESP:** Dyspnea

**SKIN:** Ecchymosis, erythema, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**

**Other:** **Anaphylaxis**; injection-site pain, redness, and swelling; superinfection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cefepime cautiously in patients with impaired renal function or a history of GI disease, particularly colitis. Also use cautiously in patients hypersensitive to other cephalosporins, other drugs, or penicillins because cross-sensitivity has occurred.
- Obtain culture and sensitivity test results, if possible and as ordered, before giving drug.
- For I.V. infusion, reconstitute using manufacturer's guidelines. Give over 30 minutes.
- For I.M. injection, reconstitute 500-mg vial of drug with 1.3 ml of diluent, such as sterile water for injection (or 1-g vial with 2.4 ml of diluent). See drug guidelines for complete list of appropriate diluents.

**WARNING** Monitor patient closely for hypersensitivity reactions. Be aware that an allergic reaction may occur even up to a few days after therapy starts. Notify prescriber immediately and expect cefepime to be discontinued. Be prepared to administer treatment with corticosteroids, epinephrine, intravenous fluids, intravenous antihistamines, oxygen, pressor amines and airway management, if reaction is severe.

- Monitor BUN and serum creatinine levels for early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.

- Be aware that in renally impaired patients, neurotoxicity may occur, especially if dosage has not been adjusted for their degree of renal impairment. If neurotoxicity occurs, notify prescriber and expect dosage to be modified or drug discontinued.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Assess for signs of superinfection, such as cough or sputum changes, diarrhea, drainage, fever, malaise, pain, perineal itching, rash, redness, and swelling.
- Assess for arthralgia, bleeding, ecchymosis, and pharyngitis; they may indicate a blood dyscrasia. Be aware that positive direct Coombs' tests may occur with cefepime use. Expect drug to be discontinued and appropriate therapy instituted if patient develops hemolytic anemia.
- Monitor patient for evidence of neurotoxicity such as aphasia, encephalopathy, myoclonus, nonconvulsive status epilepticus, or seizures. Be prepared to provide immediate treatment, as ordered. Be aware that although most cases occurred in patients with renal impairment who did not receive appropriate dosage adjustment, some did not.

## **PATIENT TEACHING**

- Tell patient to immediately report severe diarrhea to prescriber, even if it occurs as late as 2 or more months after the last dose was taken.
- Instruct patient and caregiver to immediately seek emergency care for any change in mental status, development of seizure activity, difficulty speaking or understanding spoken or written words, or sudden jerking movements. Cefepime should be stopped until patient is evaluated.
- Alert patients with diabetes that cefepime therapy may result in a false-positive reaction for glucose in the urine when using some methods such as Clinitest tablets.

**cefiderocol**

**Fetroja**

# Class and Category

*Pharmacologic class:* Cephalosporin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat complicated urinary tract infections, including pyelonephritis caused by Enterobacter cloacae complex, Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis, or Pseudomonas aeruginosa*

### I.V. INFUSION

**Adults with a creatinine clearance between 60 and 119 ml/min.** 2 g infused over 3 hr every 8 hr for 7 to 14 days.

***DOSAGE ADJUSTMENT*** For patients with renal impairment and a creatinine clearance between 30 to 59 ml/min, dosage reduced to 1.5 g every 8 hr; creatinine clearance between 15 to 29 ml/min, dosage reduced to 1 g every 8 hr; and for creatinine clearance of less than 15 ml/min, dosage reduced to 0.75 g every 12 hr. For patients who are receiving intermittent hemodialysis, dosage reduced to 0.75 g every 12 hr. For patients with a creatinine clearance of 120 ml/min or greater, dosage remains at 2 g but dosage interval decreases to every 6 hr. All dosage adjustments infused over 3 hr.

### Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die.

Cefiderocol is also a siderophore cephalosporin. It binds with extracellular free ferric iron to form a chelated complex, which then uses bacterial iron transport systems to be delivered across the outer cell membrane of the organism.

## Incompatibilities

Do not mix cefiderocol with any solution other than 0.9% sodium chloride, USP, or 5% dextrose, USP. Do not administer cefiderocol with any other drugs.

## Contraindications

Hypersensitivity to cefiderocol, other beta-lactam antibacterials, or their components

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Dysgeusia, fever, headache, insomnia, restlessness, **seizures**

**CV:** **Atrial fibrillation, bradycardia, congestive heart failure, fluid overload**, peripheral edema

**EENT:** Dry mouth, oral candidiasis, stomatitis

**GI:** Abdominal pain, anorexia, cholecystitis, cholelithiasis, ***Clostridium difficile* colitis**, constipation, diarrhea, elevated liver enzymes, gallbladder pain, nausea, vomiting

**GU:** Candiduria, urine positive for red blood cells, vulvovaginal candidiasis

**HEME:** Prolonged prothrombin time, increased international normalized ratio, thrombocytosis

**MS:** Elevated creatine phosphokinase

**RESP:** Cough, dyspnea, pleural effusion

**SKIN:** Pruritis, rash

**Other:** Hypersensitivity reactions, including anaphylaxis, hypocalcemia, hypokalemia; infusion-site reactions (erythema, inflammation, pain, phlebitis, pruritis)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Reconstitute powder in drug vial with 10 ml of either 0.9% sodium chloride injection, USP, or 5% dextrose injection, USP, and gently shake to dissolve. Allow vial to stand until foaming generated on surface has disappeared (typically 2 minutes). Final volume of reconstituted solution will be about 11.2 ml/vial. Then immediately (or up to 1 hour if kept at room temperature) withdraw appropriate volume of reconstituted solution from vial(s) (22.4 ml for a 2-g dose, 16.8 ml for a 1.5-g dose, 11.2 ml for a

1-g dose, and 8.4 ml for a 0.75-g dose) and add to 100-ml infusion bag containing either 0.9% sodium chloride injection, USP, or 5% dextrose injection, USP. Solution should be clear and colorless. Diluted solution may be stored for up to 6 hours at room temperature or up to 24 hours refrigerated. Must be protected from light. Infusion should be completed within 6 hours after removal from refrigerator.

**WARNING** Monitor patient for hypersensitivity reactions that could become severe, *especially with the first dose*. Patients who have had previous hypersensitivity reactions to other beta-lactams (including cephalosporins) or other allergens may be at higher risk for developing a serious reaction. If present, discontinue drug immediately, notify prescriber, and be prepared to provide emergency supportive care, as prescribed.

- Monitor patients for adverse reactions, especially patients with renal impairment, because drug is substantially excreted by the kidney.
- Put seizure precautions in place because cefiderocol has been implicated in triggering seizures, especially in patients with epilepsy and/or when dosage was not reduced in patients with impaired renal function. Patient should also be monitored for other signs of neurotoxicity, including confusion, tremors, or extra muscle action. Patients should be educated to report any of these signs.
- Be aware that cefiderocol may result in false-positive results in dipstick tests (ketones, occult blood, urine protein), thus requiring alternate clinical laboratory methods of testing to confirm positive tests.
- Assess bowel function daily; severe diarrhea may indicate pseudomembranous colitis caused by *C. difficile*. If diarrhea occurs, notify prescriber and expect to treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*. Cefiderocol may also have to be withheld.
- Monitor urine output hourly. Urine output less than 0.3 mL/kg/h or less than 500 mL/day should be reported to the physician.

## PATIENT TEACHING

**WARNING** Urge patient to immediately report any hypersensitivity reactions, such as hives, itching skin, or rash.

- Tell patient that diarrhea is a common problem caused by antibacterial drugs such as cefiderocol. However, if patient develops watery, bloody stools that may occur even up to 2 months after drug therapy has ended, prescriber should be notified immediately.

**cefixime**

**Suprax**

## **Class and Category**

*Pharmacologic class:* Third-generation cephalosporin

*Therapeutic class:* Antibiotic

## **Indications and Dosages**

- *To treat uncomplicated UTI caused by Escherichia coli or Proteus mirabilis; pharyngitis and tonsillitis caused by S. pyogenes; acute bronchitis and acute exacerbations of chronic bronchitis caused by H. influenzae or Streptococcus pneumoniae*

## **CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults and adolescents weighing 45 kg (99 lb) or more.** 400 mg once daily or 200 mg every 12 hr.

## CHEWABLE TABLETS, ORAL SUSPENSION

**Children age 6 months to 12 years weighing less than 45 kg (99 lb).**

8 mg/kg once daily or 4 mg/kg every 12 hr.

- *To treat otitis media caused by Haemophilus influenzae, Moraxella catarrhalis, or Streptococcus pyogenes*

## CHEWABLE TABLETS, ORAL SUSPENSION

**Adults and adolescents weighing 45 kg (99 lb) and over.** 400 mg once daily or 200 mg every 12 hr.

**Children age 6 months to 12 years weighing less than 45 kg (99 lb).** 8 mg/kg once daily or 4 mg/kg every 12 hr.

- *To treat uncomplicated gonorrhea caused by Neisseria gonorrhoeae*

## TABLETS

**Adults.** 400 mg as a single dose.

**DOSAGE ADJUSTMENT** Dosage reduced to 75% for patients who have creatinine clearance of 21 to 60 ml/min or receive hemodialysis. Dosage reduced to 50% for patients who have creatinine clearance of 20 ml/min or less or receive continuous peritoneal dialysis.

## Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

## Contraindications

Hypersensitivity to cefixime, other cephalosporins, or their components

## Interactions

### DRUGS

*anticoagulants such as warfarin*: Increased prothrombin time; increased risk of bleeding

*carbamazepine*: Increased blood carbamazepine level

## Adverse Reactions

**CNS**: Chills, dizziness, fever, headache, **seizures**

**CV**: Edema, elevated LDH level

**EENT**: Hearing loss, oral candidiasis

**GI**: Abdominal cramps, diarrhea, elevated liver enzymes, **hepatic failure**, **hepatitis**, hepatomegaly, hyperbilirubinemia, jaundice, nausea, **pseudomembranous colitis**, vomiting

**GU**: Elevated BUN or creatinine levels, genital pruritus, **nephrotoxicity**, **renal failure**, vaginal candidiasis

**HEME**: **Agranulocytosis**, eosinophilia, **hemolytic anemia**, **hypoprothrombinemia**, **leukopenia**, **neutropenia**, **pancytopenia**, **prolonged prothrombin time**, **thrombocytopenia**, **unusual bleeding**

**MS**: Arthralgia

**RESP**: Dyspnea

**SKIN**: Ecchymosis, erythema, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** Anaphylaxis, angioedema, drug fever, serum sickness-like reactions, superinfection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.  
A decision should be made to discontinue breastfeeding temporarily during drug therapy.

## Nursing Considerations

- Use cefixime cautiously in patients with impaired renal function or a history of GI disease, especially colitis. Also use cautiously in patients hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- Obtain culture and sensitivity test results, if possible and as ordered, before giving drug.
- Know that tablets shouldn't be substituted for oral suspension to treat otitis media because cefixime suspension produces a higher peak blood level than do tablets when administered at the same dose.
- Monitor BUN and serum creatinine for early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Be aware that an allergic reaction may occur a few days after therapy starts.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.

- Assess for signs of superinfection, such as cough or sputum changes, diarrhea, drainage, fever, malaise, pain, perineal itching, rash, redness, and swelling.
- Assess for arthralgia, bleeding, ecchymosis, and pharyngitis; they may indicate a blood dyscrasia.

## PATIENT TEACHING

- Instruct patient to complete the prescribed course of therapy.
- Advise patient to shake oral suspension well before pouring dose and to use a calibrated device to obtain an accurate dose.
- Instruct patient to store oral suspension at room temperature and to discard unused portion after 14 days.
- Alert patient that chewable tablets contain aspartame, a source of phenylalanine, which can be harmful to patients with phenylketonuria (PKU).
- Tell patient to report severe diarrhea to prescriber immediately; this may occur even up to 2 months after cefixime therapy has been discontinued.
- Inform patient that buttermilk and yogurt can help maintain intestinal flora and decrease diarrhea.
- Teach patient to recognize and report signs of superinfection, such as furry tongue, perineal itching, and loose, foul-smelling stools.

# cefotaxime sodium

## Claforan

## Class and Category

*Pharmacologic class:* Third-generation cephalosporin

*Therapeutic class:* Antibiotic

# Indications and Dosages

- *To provide perioperative prophylaxis*

## **I.V. INFUSION, I.V. OR I.M. INJECTION**

**Adults and children weighing 50 kg (110 lb) or more.**

1 g 30 to 90 min before surgery. Then 1 g 1.5 to 2 hr after first dose. For lengthy procedures, additional intraoperative doses administered, if needed 1.5 to 2 hrs during surgery. Then 1 g within 2 hr after completion of surgery. *Maximum:* 12 g daily. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min.

- *To provide perioperative prophylaxis related to cesarean section*

## **I.V. INFUSION, I.V. OR I.M. INJECTION**

**Adults.** 1 g as soon as cord is clamped, then 1 g every 6 hr for up to two doses. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min.

- *To treat gonococcal urethritis and cervicitis in men and women*

## **I.M. INJECTION**

**Adults.** 500 mg as a single dose.

- *To treat rectal gonorrhea in women*

## **I.M. INJECTION**

**Adults.** 500 mg as a single dose.

- *To treat rectal gonorrhea in men*

## **I.M. INJECTION**

**Adults.** 1 g as a single dose.

- *To treat uncomplicated infections caused by susceptible organisms*

## **I.V. INFUSION, I.V. OR I.M. INJECTION**

**Adults and children weighing 50 kg (110 lb) or more.** 1 g every 12 hr. I.V. injection given over at least 3 to 5 min. I. V. infusion given over longer than 5 min.

**Children ages 1 month to 12 years weighing less than 50 kg.** 50 to 180 mg/kg daily in four to six divided doses. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min.

**Children ages 1 to 4 weeks.** 50 mg/kg I.V. every 8 hr. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min.

**Children age 1 week and under.** 50 mg/kg I.V. every 12 hr. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min.

- *To treat moderate to severe infections caused by susceptible organisms*

## **I.V. INFUSION, I.V. OR I.M. INJECTION**

**Adults and children weighing 50 kg (110 lb) or more.** 1 to 2 g every 8 hr. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min.

**Children ages 1 month to 12 years weighing less than 50 kg.** 50 to 180 mg/kg daily in four to six divided doses. For more serious infections, including meningitis, the higher dosages are used. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min.

**Children ages 1 to 4 weeks.** 50 mg/kg I.V. every 8 hr. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min.

**Children age 1 week and younger.** 50 mg/kg I.V. every 12 hr. I.V. injection given over at least 3 to 5 min. I.V.

infusion given over longer than 5 min.

- *To treat septicemia and other infections that commonly require antibiotics in higher doses than those used to treat moderate to severe infections*

## **I.V. INFUSION OR INJECTION**

**Adults and children weighing 50 kg (110 lb) or more.**

2 g every 6 to 8 hr. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min.

- *To treat life-threatening infections caused by susceptible organisms*

## **I.V. INFUSION OR INJECTION**

**Adults and children weighing 50 kg (110 lb) or more.**

2 g every 4 hr. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min. *Maximum:* 12 g daily.

**Children ages 1 month to 12 years weighing less than**

**50 kg.** 50 to 180 mg/kg daily in four to six divided doses.

I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min.

**Children ages 1 to 4 weeks.** 50 mg/kg every 8 hr. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min.

**Children age 1 week and younger.** 50 mg/kg every 12 hr. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min.

***DOSAGE ADJUSTMENT*** Dosage reduced by 50% for patients with estimated creatinine clearance below 20 ml/min.

## **Mechanism of Action**

Interferes with bacterial cell wall synthesis by inhibiting cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

## Incompatibilities

To prevent mutual inactivation, don't mix cefotaxime with aminoglycosides. Also avoid mixing cefotaxime with other drugs, including pentamidine isethionate.

## Contraindications

Hypersensitivity to cefotaxime, other cephalosporins, or their components

## Interactions

### DRUGS

*aminoglycosides, loop diuretics, NSAIDs*: Increased risk of nephrotoxicity

*probenecid*: Increased and prolonged blood cefotaxime level

## Adverse Reactions

**CNS**: Chills, fever, headache, **seizures**

**CV**: Edema

**EENT**: Hearing loss, oral candidiasis

**GI**: Abdominal cramps, cholestasis, diarrhea, elevated enzymes, **hepatic failure, hepatitis**, hepatomegaly, jaundice, nausea, **pseudeomembranous colitis**, vomiting

**GU:** Elevated BUN level, **nephrotoxicity**, **renal failure**, vaginal candidiasis

**HEME:** Eosinophilia, **hemolytic anemia**, **hypoprothrombinemia**, **neutropenia**, **thrombocytopenia**, **unusual bleeding**

**MS:** Arthralgia

**RESP:** Dyspnea

**SKIN:** Ecchymosis, erythema, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other:** **Anaphylaxis**; injection-site pain, redness, and swelling; superinfection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cefotaxime cautiously in patients with impaired renal function, a history of GI disease (especially colitis), or hypersensitivity to penicillin because cross-sensitivity has occurred in about 10% of such patients.

- Obtain culture and sensitivity test results, if possible and as ordered, before giving drug.
- For I.V. use, reconstitute each 0.5-, 1-, or 2-g vial with 10 ml of sterile water for injection. Shake to dissolve.
- For intermittent I.V. infusion, further dilute in 50 to 100 ml of D<sub>5</sub>W or normal saline solution.
- For I.M. use, reconstitute each 500-mg vial with 2 ml sterile water for injection or bacteriostatic water for injection; each 1-g vial with 3 ml diluent; and each 2-g vial with 5 ml diluent. Shake to dissolve.

**WARNING** Don't use diluent that contains benzyl alcohol when preparing drug for a neonate; it could cause a fatal toxic syndrome.

- Give cefotaxime by I.V. injection over 3 to 5 minutes through tubing of a free-flowing compatible I.V. solution. Temporarily stop other solutions being given through same I.V. site.
- Discard unused drug after 24 hours if stored at room temperature, 5 days if refrigerated.
- Protect cefotaxime powder and solution from light and heat.
- Monitor I.V. sites for signs of phlebitis or extravasation. Rotate I.V. sites every 72 hours.
- Monitor BUN and serum creatinine levels and fluid intake and output for signs of nephrotoxicity.
- Be aware that allergic reaction may occur a few days after cefotaxime therapy starts.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold cefotaxime and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.
- Assess patient for arthralgia, bleeding, ecchymosis, and pharyngitis, which may indicate a blood dyscrasia. Monitor bleeding time, CBC, and PT, as ordered.
- Monitor patient closely for superinfection. If evidence appears, notify prescriber and expect to stop drug and provide care.

- Be aware that cephalosporins, such as cefotaxime, may produce a positive direct Coombs' test.

## PATIENT TEACHING

- Explain that I.M. injection may be painful.
- Instruct patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

# cefotetan disodium

## Class and Category

*Pharmacologic class:* Second-generation cephalosporin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To provide surgical prophylaxis*

### I.V. INJECTION

**Adults.** 1 to 2 g given over 3 to 5 min 30 to 60 min before surgery or, in cesarean section, as soon as cord is clamped.

- *To treat lower respiratory tract infections caused by Escherichia coli, Haemophilus influenzae, Klebsiella species, Proteus mirabilis, Serratia marcescens, Staphylococcus aureus, or Streptococcus pneumoniae; gynecologic infections caused by Bacteroides species (excluding B. distasonis, B. ovatus, or B. thetaiotaomicron), E. coli, Fusobacterium species,*

*gram-positive anaerobic cocci, Neisseria gonorrhoeae, P. mirabilis, S. aureus, Staphylococcus epidermidis, or Streptococcus species (excluding enterococci); intra-abdominal infections caused by Bacteroides species (excluding B. distasonis, B. ovatus, or B. thetaiotaomicron), Clostridium species (other than Clostridium difficile), E. coli, Klebsiella species, or Streptococcus species (excluding enterococci); and bone and joint infections caused by S. aureus*

### **I.V. INFUSION, I.V. OR I.M. INJECTION**

**Adults.** For mild to moderate infections, 1 to 2 g every 12 hr. For I.V. injection, given over 3 to 5 min; for I.V. infusion, given over more than 5 min.

### **I.V. INFUSION OR INJECTION**

**Adults.** For severe infections, 2 g every 12 hr; for life-threatening infections, 3 g every 12 hr. For I.V. injection, given over 3 to 5 min; for I.V. infusion, given over more than 5 min.

- *To treat UTI caused by E. coli, Klebsiella species, Morganella organii, P. mirabilis, P. vulgaris, or Providencia rettgeri*

### **I.V. INFUSION, I.V. OR I.M. INJECTION**

**Adults.** 0.5 to 2 g every 12 hr or 1 to 2 g every 24 hr. For I.V. injection, given over 3 to 5 min; for I.V. infusion, given over more than 5 min.

- *To treat skin and soft-tissue infections caused by E. coli, Klebsiella pneumoniae, Peptostreptococcus species, S. aureus, S. epidermidis, Streptococcus pyogenes, and Streptococcus species (excluding enterococci)*

## **I.V. INFUSION, I.V. OR I.M. INJECTION**

**Adults.** For mild to moderate infections due to *K. pneumoniae*, 1 or 2 g every 12 hr. For mild to moderate infections caused by other organisms, 1 g I.M. or I.V. every 12 hr or 2 g I.V. every 24 hr; for severe infections, 2 g I.V. every 12 hr. For I.V. injection, given over 3 to 5 min; for I.V. infusion, given over more than 5 min.

**DOSAGE ADJUSTMENT** Dosing interval reduced to 24 hr if creatinine clearance is 10 to 30 ml/min and to 48 hr if creatinine clearance is less than 10 ml/min.

## **Mechanism of Action**

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

## **Incompatibilities**

To prevent mutual inactivation, don't mix cefotetan with aminoglycosides.

## **Contraindications**

History of cephalosporin-induced hemolytic anemia; hypersensitivity to cefotetan, other cephalosporins, or their components

## **Interactions**

## **DRUGS**

*aminoglycosides, loop diuretics*: Increased risk of nephrotoxicity

*probenecid*: Increased and prolonged blood cefotetan level

## **ACTIVITIES**

*alcohol use*: Disulfiram-like reaction

## **Adverse Reactions**

**CNS**: Chills, fever, headache, **seizures**

**CV**: Edema

**EENT**: Hearing loss, oral candidiasis

**GI**: Abdominal cramps, diarrhea, elevated liver enzymes, **hepatic failure**, hepatomegaly, nausea, **pseudomembranous colitis**, vomiting

**GU**: Elevated BUN level, **nephrotoxicity**, **renal failure**, vaginal candidiasis

**HEME**: Eosinophilia, **hemolytic anemia**, **hypoprothrombinemia**, **neutropenia**, **thrombocytopenia**, **unusual bleeding**

**MS**: Arthralgia

**RESP**: Dyspnea

**SKIN**: Ecchymosis, erythema, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**

**Other**: **Anaphylaxis**; injection-site pain, redness, and swelling; superinfection

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Use cefotetan cautiously in patients with impaired renal function or a history of GI disease, especially colitis. Also use cautiously in patients hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- Obtain culture and sensitivity test results, if possible and as ordered, before giving drug.
- For I.V. use, reconstitute each 1-g vial of drug with 10 ml sterile water for injection. For each 2-g vial, use 10 to 20 ml diluent. For I.V. infusion, further dilute solution in 50 to 100 ml D<sub>5</sub>W or normal saline solution.
- For direct I.V. injection, give drug slowly over 3 to 5 minutes through tubing of a flowing compatible I.V. solution.
- For I.M. use, reconstitute each 1-g vial of drug with 2 ml of sterile or bacteriostatic water for injection, or sodium chloride for injection. For a 2-g vial, use 3 ml diluent.
- Monitor I.V. site for signs and symptoms of phlebitis and extravasation; rotate sites every 72 hours.
- Protect reconstituted solution from light, and store for up to 24 hours at room temperature or 96 hours under refrigeration.
- Be aware that an allergic reaction may occur a few days after therapy starts.
- Monitor BUN and serum creatinine levels and fluid intake and output for signs of nephrotoxicity.
- Monitor patient receiving even short-term cefotetan therapy for signs and symptoms of hemolytic anemia, such as marked pallor and fatigue.

- Monitor ALT, AST, bilirubin, CBC, LD, and serum alkaline phosphatase levels if patient receives long-term therapy.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Watch for arthralgia, bleeding, ecchymosis, and pharyngitis which may indicate a blood dyscrasia. Monitor PT and bleeding time, as ordered. Be prepared to give vitamin K, if ordered, to treat hypoprothrombinemia.

## PATIENT TEACHING

- Explain that I.M. injection may be painful.
- Tell patient to immediately report severe diarrhea to prescriber even up to 2 months after therapy has stopped.
- Urge patient to avoid alcohol during and for at least 3 days after cefotetan therapy.

## cefoxitin sodium

### Mefoxin

## Class and Category

*Pharmacologic class:* Second-generation cephalosporin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To provide surgical prophylaxis in patients undergoing uncontaminated abdominal or vaginal hysterectomy or gastrointestinal surgery*

## I.V. INFUSION OR INJECTION

**Adults.** 2 g 30 to 60 min before surgery and then 2 g every 6 hr after first dose for up to 24 hr. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min.

**Children age 3 months or over.** 30 to 40 mg/kg 30 to 60 min before surgery and every 6 hr after first dose for up to 24 hr. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min.

- *To provide surgical prophylaxis for cesarean section*

## I.V. INFUSION OR INJECTION

**Adults.** 2 g as a single dose as soon as cord is clamped; or 2 g as soon as cord is clamped, followed by 2 g 4 and 8 hr after initial dose. I.V. injection given over at least 3 to 5 min. I.V. infusion given over more than 5 min.

- *To treat bone and joint infections caused by Staphylococcus aureus; gynecological infections, including endometritis and pelvic cellulitis or inflammatory disease caused by Bacteroides species, Clostridium species, E. coli, Neisseria gonorrhoeae, Peptococcus niger, Peptostreptococcus species, or Streptococcus agalactiae; intra-abdominal infections including intra-abdominal abscess and peritonitis caused by Bacteroides or Clostridium species, E. coli, or Klebsiella species; lower respiratory infections, including lung abscess and pneumonia caused by Bacteroides species, E. coli, Haemophilus influenzae, Klebsiella species, S. aureus, Streptococcus pneumoniae, and other streptococci (excluding enterococci); skin and skin structure infections caused by Bacteroides and Clostridium species, Enterococcus faecalis, E. coli, P. niger, Peptostreptococcus species,*

*Proteus mirabilis*, *S. aureus*, *S. epidermidis*, *S. pyogenes*, and other streptococci (excluding enterococci); septicemia caused by *Bacteroides* species, *E. coli*, *Klebsiella species*, *S. aureus* or *S. pneumoniae*; and urinary tract infections caused by *E. coli*, *Klebsiella species*, *Morganella morganii*, *P. mirabilis*, *P. vulgaris*, or *Providencia species*

## **I.V. INFUSION OR INJECTION**

**Adults.** For uncomplicated infections, 1 g every 6 to 8 hr; for moderate to severe infections, 1 g 4 hr or 2 g every 6 to 8 hr. For infections that commonly require high-dose antibiotics (such as gas gangrene), 2 g every 4 hr, or 3 g every 6 hr. I.V. injection given over at least 3 to 5 min. I.V. infusion given over more than 5 min with higher doses given continuously.

**Children age 3 months or over.** 80 to 160 mg/kg daily in equally divided doses given every 4 to 6 hr (higher dosages used for more severe infections). *Maximum:* 12 g daily. I.V. injection given over at least 3 to 5 min. I.V. infusion given over longer than 5 min with higher doses given continuously.

***DOSAGE ADJUSTMENT*** Dosage reduced to 1 to 2 g every 8 to 12 hr if creatinine clearance is 30 to 50 ml/min; 1 to 2 g every 12 to 24 hr if clearance is 10 to 29 ml/min; 0.5 to 1 g every 12 to 24 hr if clearance is 5 to 9 ml/min; and 0.5 to 1 g every 24 to 48 hr if clearance is less than 5 ml/min.

## **Mechanism of Action**

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

# Incompatibilities

To prevent mutual inactivation, don't mix cefoxitin with aminoglycosides. Also avoid mixing cefoxitin with other drugs, including pentamidine isethionate.

# Contraindications

Hypersensitivity to cefoxitin, other cephalosporins, or their components

# Interactions

## DRUGS

*aminoglycosides, loop diuretics*: Increased risk of nephrotoxicity

# Adverse Reactions

**CNS**: Chills, fever, headache, **seizures**

**CV**: Edema

**EENT**: Hearing loss, oral candidiasis

**GI**: Abdominal cramps, diarrhea, elevated liver enzymes, **hepatic failure**, hepatomegaly, nausea, **pseudomembranous colitis**, vomiting

**GU**: Elevated BUN level, **nephrotoxicity**, **renal failure**, vaginal candidiasis

**HEME**: Eosinophilia, **hemolytic anemia**, **hypoprothrombinemia**, **neutropenia**, **thrombocytopenia**, **unusual bleeding**

**MS**: Arthralgia

**RESP:** Dyspnea

**SKIN:** Ecchymosis, erythema, **erythema multiforme**, flushing, pruritus, rash, **Stevens-Johnson syndrome**, urticaria

**Other:** **Anaphylaxis**; injection-site pain, redness, and swelling; superinfection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cefoxitin cautiously in patients hypersensitive to penicillin; cross-sensitivity has occurred in about 10% of such patients.
- Use cautiously in patients with a history of GI disease, particularly colitis, because of an increased risk of pseudomembranous colitis.
- Obtain culture and sensitivity test results, if possible and as ordered, before giving drug.
- For I.V. use, reconstitute 1 g with 10 ml sterile water for injection, or 2 g with 10 to 20 ml diluent.
- For I.V. injection, give slowly over 3 to 5 minutes through tubing of a flowing compatible I.V. solution.

- For intermittent infusion, further dilute with 50 to 100 ml D<sub>5</sub>W or normal saline solution.
- For continuous high-dose infusion, add cefoxitin to I.V. solutions of D<sub>5</sub>W, normal saline solution, or dextrose 5% in normal saline solution.
- Discard unused drug after 24 hours if stored at room temperature, or after 1 week if refrigerated.
- Be aware that powder or solution may darken during storage, which doesn't reflect altered potency.
- Be aware that an allergic reaction may occur a few days after therapy starts.
- Monitor BUN and serum creatinine for early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Assess for arthralgia, bleeding, ecchymosis, and pharyngitis; they may indicate a blood dyscrasia.

## PATIENT TEACHING

- Tell patient to report severe diarrhea to prescriber immediately.
- Instruct patient to complete the course of therapy as prescribed.

# cefepodoxime proxetil

## Class and Category

*Pharmacologic class:* Third-generation cephalosporin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat acute community-acquired pneumonia caused by Haemophilus influenzae or Streptococcus pneumoniae*

## **ORAL SUSPENSION, TABLETS**

**Adults and adolescents.** 200 mg every 12 hr for 14 days.

- *To treat acute bacterial exacerbation of chronic bronchitis caused by H. influenzae, Moraxella catarrhalis, or S. pneumoniae*

## **TABLETS**

**Adults and adolescents.** 200 mg every 12 hr for 10 days.

- *To treat uncomplicated gonorrhea in men and women and rectal gonococcal infections in women caused by Neisseria gonorrhoeae*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 200 mg as a single dose.

- *To treat uncomplicated UTI caused by Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis, or Staphylococcus saprophyticus*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 100 mg every 12 hr for 7 days.

- *To treat uncomplicated skin and soft-tissue infections caused by S. aureus or S. pyogenes*

## **ORAL SUSPENSION, TABLETS**

**Adults and adolescents.** 400 mg every 12 hr for 7 to 14 days.

- *To treat acute otitis media caused by H. influenzae, M. catarrhalis, S. pneumoniae, or S. pyogenes*

## **ORAL SUSPENSION, TABLETS**

**Children ages 2 months through 12 years.** 5 mg/kg every 12 hr for 5 days. *Maximum: 200 mg/dose.*

- *To treat pharyngitis and tonsillitis caused by S. pyogenes*

## **ORAL SUSPENSION, TABLETS**

**Adults and adolescents.** 100 mg every 12 hr for 5 to 10 days.

**Children ages 2 months through 12 years.** 5 mg/kg every 12 hr for 5 to 10 days. *Maximum: 100 mg/dose.*

- *To treat acute maxillary sinusitis caused by H. influenzae, M. catarrhalis, or S. pneumoniae*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 200 mg every 12 hr for 10 days.

**Children ages 2 months through 12 years.** 5 mg/kg every 12 hr for 10 days. *Maximum: 200 mg/dose.*

***DOSAGE ADJUSTMENT*** Dosing interval increased to 24 hr in patients with creatinine clearance less than 30 ml/min. For patients on hemodialysis, dosage frequency reduced to 3 times a week and given after hemodialysis.

## **Mechanism of Action**

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes cell membranes rigid and protective. Without it, bacterial cells rupture and die.

# Contraindications

Hypersensitivity to cefpodoxime, other cephalosporins, or their components

# Interactions

## DRUGS

*aminoglycosides, loop diuretics*: Increased risk of nephrotoxicity

*antacids (high doses of aluminum hydroxide or sodium bicarbonate), H<sub>2</sub>-receptor antagonists*: Reduced bioavailability and blood level of cefpodoxime

*probenecid*: Possibly increased and prolonged blood cefpodoxime level

# Adverse Reactions

**CNS**: Chills, fever, headache, **seizures**

**CV**: Edema

**EENT**: Hearing loss, oral candidiasis

**GI**: Abdominal cramps, diarrhea, elevated liver enzymes, **hepatic failure**, hepatomegaly, nausea, **pseudomembranous colitis**, vomiting

**GU**: Elevated BUN level, **nephrotoxicity**, **renal failure**, vaginal candidiasis

**HEME**: Eosinophilia, **hemolytic anemia**, **hypoprothrombinemia**, **neutropenia**, **thrombocytopenia**, **unusual bleeding**

**MS**: Arthralgia

**RESP**: Dyspnea

**SKIN:** Ecchymosis, erythema, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**

**Other:** **Anaphylaxis**, superinfection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding temporarily during drug therapy or discontinue the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Use cefpodoxime cautiously in patients who have impaired renal function or are receiving potent diuretics. Also use drug cautiously in patients hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- Obtain culture and sensitivity test results, if possible and as ordered, before giving cefpodoxime.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Be aware that an allergic reaction may occur a few days after therapy starts.

### PATIENT TEACHING

- Urge patient to complete the prescribed course of therapy.
- Tell patient to take tablets with food to enhance absorption.
- Advise patient to refrigerate oral suspension and discard after 14 days.
- Instruct patient to shake oral suspension bottle well before pouring dose and to use a calibrated liquid-measuring device to ensure accurate doses.
- Inform patient that buttermilk and yogurt can help maintain intestinal flora and decrease diarrhea.
- Warn patient not to take an antacid within 2 hours before or after taking cefpodoxime.
- Tell patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

## cefprozil

### Class and Category

*Pharmacologic class:* Second-generation cephalosporin

*Therapeutic class:* Antibiotic

### Indications and Dosages

- *To treat secondary bacterial infections in patients with acute bronchitis and acute bacterial exacerbations of chronic bronchitis caused by Haemophilus influenzae, Moraxella catarrhalis, and Streptococcus pneumoniae*

### ORAL SUSPENSION, TABLETS

**Adults and adolescents.** 500 mg every 12 hr for 10 days.

- *To treat uncomplicated skin and soft-tissue infections caused by Staphylococcus aureus and Streptococcus*

pyogenes

## ORAL SUSPENSION, TABLETS

**Adults and adolescents.** 250 mg every 12 hr or 500 mg every 12 to 24 hr for 10 days.

**Children ages 2 to 12.** 20 mg/kg every 24 hr for 10 days. *Maximum:* Not to exceed adult dose.

- *To treat pharyngitis and tonsillitis caused by S. pyogenes*

## ORAL SUSPENSION, TABLETS

**Adults and adolescents.** 500 mg every 24 hr for 10 days.

**Children ages 2 to 12.** 7.5 mg/kg every 12 hr for 10 days. *Maximum:* Not to exceed adult dose.

- *To treat otitis media caused by H. influenzae, M. catarrhalis, and S. pneumoniae*

## ORAL SUSPENSION, TABLETS

**Children ages 6 months to 12 years.** 15 mg/kg every 12 hr for 10 days.

- *To treat acute sinusitis caused by H. influenzae, M. catarrhalis, and S. pneumoniae*

## ORAL SUSPENSION, TABLETS

**Adults and adolescents.** 250 to 500 mg every 12 hr for 10 days.

**Children ages 6 months to 12 years.** 7.5 or 15 mg/kg every 12 hr for 10 days. *Maximum:* Not to exceed adult dose.

***DOSAGE ADJUSTMENT*** Dosage reduced by half and given at usual intervals in patients with creatinine clearance less than 30 ml/min.

# Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die.

# Contraindications

Hypersensitivity to cefprozil, other cephalosporins, or their components

# Interactions

## DRUGS

*aminoglycosides, loop diuretics*: Increased risk of nephrotoxicity  
*probenecid*: Increased blood cefprozil level

# Adverse Reactions

**CNS**: Chills, fever, headache, **seizures**

**CV**: Edema

**EENT**: Hearing loss, oral candidiasis

**GI**: Abdominal cramps, diarrhea, elevated liver enzymes, **hepatic failure**, hepatomegaly, nausea, **pseudomembranous colitis**, vomiting

**GU**: Elevated BUN level, **nephrotoxicity**, **renal failure**, vaginal candidiasis

**HEME**: Eosinophilia, **hemolytic anemia**, **hypoprothrombinemia**, **neutropenia**, **thrombocytopenia**, **unusual bleeding**

**MS:** Arthralgia

**RESP:** Dyspnea

**SKIN:** Ecchymosis, erythema, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**

**Other:** **Anaphylaxis**, superinfection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cefprozil cautiously in patients who have impaired renal function or a history of GI disease, especially colitis. Also use drug cautiously in patients who are hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- Obtain culture and sensitivity test results, if possible and as ordered, before giving drug.

**WARNING** Don't administer oral suspension to patients with phenylketonuria because it contains phenylalanine 28 mg/5 ml.

- Monitor BUN and serum creatinine levels to detect early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Be aware that an allergic reaction may occur a few days after therapy starts.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.

## PATIENT TEACHING

- Urge patient to complete the prescribed course of therapy.
- Tell patient to refrigerate oral suspension and discard after 14 days.
- Instruct patient to shake oral suspension well before pouring and to use a calibrated measuring device to ensure accurate doses.
- Inform patient that buttermilk and yogurt can help maintain intestinal flora and decrease diarrhea.
- Tell patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

**ceftaroline fosamil**

**Teflaro**

## Class and Category

*Pharmacologic class:* Fifth-generation cephalosporin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat acute bacterial skin and skin structure infection caused by Escherichia coli, Klebsiella oxytoca, K. pneumoniae, Staphylococcus aureus, Streptococcus agalactiae, or S. pyogenes*

## **I.V. INFUSION**

**Adults.** 600 mg administered over 5 to 60 min every 12 hr for 5 to 14 days.

**Children ages 2 to 18 years weighing more than 33 kg (72.5 lb).** 400 mg every 8 hr or 600 mg every 12 hr administered over 5 to 60 min for 5 to 14 days.

**Children ages 2 to 18 years weighing 33 kg (72.5 lb) or less.** 12 mg/kg every 8 hr administered over 5 to 60 min for 5 to 14 days.

**Children 2 months to less than 2 years.** 8 mg/kg every 8 hr administered over 5 to 60 min for 5 to 14 days.

**Newborns to less than 2 months of age.** 6 mg/kg every 8 hours administered over 30 to 60 min for 5 to 14 days.

- *To treat community-acquired bacterial pneumonia caused by E. coli, Haemophilus influenzae, K. oxytoca, K. pneumoniae, S. aureus, or S. pneumoniae*

## **I.V. INFUSION**

**Adults.** 600 mg administered over 5 to 60 min every 12 hr for 5 to 7 days.

**Children ages 2 to 18 years weighing more than 33 kg (72.5 lb).** 400 mg every 8 hr or 600 mg every 12 hr administered over 5 to 60 min for 5 to 14 days.

**Children ages 2 to 18 years weighing 33 kg (72.5 lb) or less.** 12 mg/kg every 8 hr administered over 5 to 60 min for 5 to 14 days.

**Children 2 months to less than 2 years.** 8 mg/kg every 8 hr administered over 5 to 60 min for 5 to 14 days

**DOSAGE ADJUSTMENT** For adult patients with a creatinine clearance above 30 ml/min but no higher than 50 ml/min, dosage reduced to 400 mg every 12 hr; for adult patients with a creatinine clearance above 15 ml/min but no higher than 30 ml/min, dosage reduced to 300 mg every 12 hr; for adult patients with a creatinine clearance of less than 15 ml/min including those on hemodialysis, dosage reduced to 200 mg every 12 hr. For pediatric patients, dosage adjustment is unknown if creatinine clearance is below 50 ml/min.

## **Mechanism of Action**

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die. Ceftaroline is unique in that it is effective against methicillin-resistant *S. aureus*, unlike other cephalosporins.

## **Incompatibilities**

Don't mix parenteral ceftaroline with any other drug because compatibility is not known.

## **Contraindications**

Hypersensitivity to ceftaroline, other cephalosporins, or their components

## **Drug Reactions**

None reported

# Adverse Reactions

**CNS:** Dizziness, fever, headache, **seizures**

**CV:** **Bradycardia**, palpitations, phlebitis

**ENDO:** Hyperglycemia

**GI:** Abdominal pain, ***Clostridium difficile*-associated diarrhea**, constipation, diarrhea, elevated liver enzymes, **hepatitis**, nausea, vomiting

**GU:** **Renal failure**

**HEME:** **Agranulocytosis**, anemia, **hemolytic anemia**, eosinophilia, **leukopenia**, **neutropenia**, **thrombocytopenia**

**RESP:** **Eosinophilic pneumonia**

**SKIN:** Pruritus, rash, urticaria

**Other:** **Anaphylaxis**, direct Coombs' test seroconversion, **hyperkalemia**, **hypokalemia**, **hypersensitivity reactions**

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Use ceftaroline cautiously in patients hypersensitive to penicillins or carbapenems because cross-sensitivity may occur.
- Obtain culture and sensitivity results, if possible and as ordered, before giving drug.
- Reconstitute each drug vial with 20 ml of sterile water for injection. Mix gently to ensure drug is completely dissolved. Color may range from clear to light to dark yellow, depending on the concentration and storage conditions. Then further dilute in 250 ml of appropriate solution such as dextrose in water, half normal saline, lactated Ringer's solution, or normal saline solution.
- Infuse reconstituted solution within 6 hours of mixing if stored at room temperature or within 24 hours if refrigerated.
- Administer as an I.V. infusion over 5 minutes to 1 hour.
- Monitor patient for hypersensitivity to ceftaroline. If present, discontinue ceftaroline, as ordered, and prepare to provide emergency supportive care.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis caused by *C. difficile*. If diarrhea occurs, notify prescriber and expect to withhold drug and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.
- Be aware that seroconversion from a negative to a positive direct Coombs' test result may occur. If anemia develops during or after ceftaroline therapy, expect a direct Coombs' test to be ordered. If drug-induced hemolytic anemia is suspected, expect to discontinue the drug and provide supportive care, as indicated.

## PATIENT TEACHING

- Urge patient to report hypersensitivity reactions, such as a rash, immediately.
- Instruct patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

# ceftazidime

**Fortaz, Tazicef**

## Class and Category

*Pharmacologic class:* Third-generation cephalosporin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat UTI caused by Enterobacterspecies, Escherichia coli, Klebsiellasppecies, Proteus mirabilisand other species such as indole-positive Proteus, or Pseudomonas aeruginosa*

## I.V. INFUSION, I.V. INJECTION, I.M. INJECTION

**Adults and children age 12 and over.** 250 mg every 12 hr. for uncomplicated UTI and 500 mg every 8 to 12 hours for complicated UTI. I.V. injection given over 3 to 5 min; I.V. infusion given over longer than 5 min.

- *To treat lower respiratory tract infections, including pneumonia, caused by Citrobaacterspecies, Enterobacterspecies, Escherichia coli, Haemophilus influenzae, Klebsiellasppecies, P. mirabilis, P. aeruginosaand other Pseudomonasspecies, Serratiaspecies, Staphococcus pneumoniae, or Streptococcus pneumoniae; mild skin and skin-structure infections caused by Enterobacterspecies, E. coli, Klebsiellasppecies, P. mirabilis and other Proteusspecies including indole-postive Proteus,*

*Pseudomonas aeruginosa, Serratia species, S. aureus, or Streptococcus pyogenes (group A beta-hemolytic streptococci)*

## **I.V. INFUSION, I.V. INJECTION, I.M. INJECTION**

**Adults and children age 12 and over.** 0.5 to 1 g every 8 hr. I.V. injection given over at least 3 to 5 min; I.V. infusion given longer than 5 min.

- *To treat bone and joint infections caused by Enterobacter species, Klebsiella species, P. aeruginosa, or S. aureus*

## **I.V. INFUSION, I.V. INJECTION**

**Adults and children age 12 and over.** 2 g every 12 hr. I.V. injection given over 3 to 5 min; I.V. infusion given longer than 5 min.

- *To treat serious gynecologic infections caused by E. coli; to treat intra-abdominal infections caused by E. coli, Klebsiella species, or S. aureus; to treat meningitis caused by H. influenzae or Neisseria meningitidis; and life-threatening infections, such as bacterial septicemia caused by E. coli, H. influenzae, Klebsiella species, P. aeruginosa, Serratia species, S. aureus, or S. pneumoniae especially in immunocompromised patients*

## **I.V. INFUSION, I.V. INJECTION**

**Adults and children age 12 and over.** 2 g every 8 hr. I.V. injection given over 3 to 5 min; I.V. infusion given over longer than 5 min.

- *To treat pseudomonal lung infection in patients with cystic fibrosis and normal renal function*

## **I.V. INFUSION, I.V. INJECTION**

**Adults and children 1 month and over.** 30 to 50 mg/kg every 8 hr. *Maximum:* 6 g daily. I.V. injection given over 3 to 5 min; I.V. infusion given longer than 5 min.

**Neonates from birth to 4 weeks.** 30 mg/kg every 12 hr. I.V. injection given over 3 to 5 min; I.V. infusion given longer than 5 min.

***DOSAGE ADJUSTMENT*** Dosage reduced to 1 g every 12 hr if creatinine clearance is 31 to 50 ml/min; to 1 g every 24 hr if 16 to 30 ml/min; to 0.5 g every 24 hr if 6 to 15 ml/min; and to 0.5 g every 48 hr if less than 6 ml/min.

## **Mechanism of Action**

Interferes with bacterial cell wall synthesis by inhibiting the cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die.

## **Incompatibilities**

Don't mix ceftazidime with aminoglycosides to prevent mutual inactivation. Vancomycin is physically incompatible with ceftazidime (precipitate may form); flush I.V. line between these drugs if given through same tubing. Avoid mixing ceftazidime with other drugs, including pentamidine isethionate.

## **Contraindications**

Hypersensitivity to ceftazidime, other cephalosporins, or their components

## **Interactions**

## DRUGS

*aminoglycosides, loop diuretics*: Increased risk of nephrotoxicity

*chloramphenicol*: Antagonistic effect on ceftazidime

*oral combined estrogen-progesterone contraceptives*: Decreased effectiveness of oral contraceptive

## Adverse Reactions

**CNS**: Chills, fever, headache, **seizures**

**CV**: Edema

**EENT**: Hearing loss, oral candidiasis

**GI**: Abdominal cramps, diarrhea, elevated liver enzymes, **hepatic failure**, hepatomegaly, nausea, **pseudomembranous colitis**, vomiting

**GU**: Elevated BUN level, **nephrotoxicity**, **renal failure**, vaginal candidiasis

**HEME**: Eosinophilia, **hemolytic anemia**, **hypoprothrombinemia**, **neutropenia**, **thrombocytopenia**, **unusual bleeding**

**MS**: Arthralgia

**RESP**: Dyspnea

**SKIN**: Ecchymosis, erythema, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**

**Other**: **Anaphylaxis**; injection-site pain, redness, and swelling; superinfection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use ceftazidime cautiously in patients hypersensitive to penicillin because cross-sensitivity occurs in about 10% of such patients. Watch for allergic reactions a few days after therapy starts.
- Use cautiously in patients with a history of GI disease, particularly colitis, because risk of pseudomembranous colitis is increased.
- Use cautiously in patients with renal insufficiency, because high and prolonged serum ceftazidime concentrations can occur from usual dosages. This can lead to asterixis, coma, encephalopathy, myoclonia, neuromuscular excitability, nonconvulsive status epilepticus, and seizures. Ensure that patients with significant renal insufficiency are receiving reduced dosage based on their creatinine clearance.
- Obtain culture and sensitivity test results, if possible and as ordered, before giving drug.
- Protect ceftazidime powder and reconstituted drug from heat and light; both tend to darken during storage.
- Thaw frozen solution at room temperature, not in water bath or microwave. Store thawed solution for up to 12 hours at room temperature or 7 days in refrigerator; don't refreeze.

**WARNING** Know that when preparing drug for neonates or immature infants, don't use diluents containing benzyl alcohol because they are linked to a fatal toxic syndrome.

- For I.V. bolus, reconstitute 1 to 2 g with 10 ml sterile water for injection, D<sub>5</sub>W, or sodium chloride for injection. Shake to dissolve. Administer I.V. injection slowly over 3 to 5 minutes through tubing of a flowing compatible I.V. fluid.
- For intermittent infusion, further dilute in 50 to 100 ml D<sub>5</sub>W or normal saline solution. Avoid using sodium bicarbonate injection as a diluent because drug is least stable in it. During ceftazidime administration, temporarily stop other solutions being given at the same I.V. site.
- For I.M. use, reconstitute each gram with 3 ml sterile water for injection or bacteriostatic water for injection.
- Give I.M. injection deep into large muscle mass, such as gluteus maximus.
- Rotate I.V. sites every 72 hours. Assess for extravasation and phlebitis.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Monitor ALT, AST, bilirubin, CBC, hematocrit, LD, and serum alkaline phosphatase, levels during long-term therapy.
- Monitor PT, as ordered, in at-risk patients, such as those with hepatic or renal impairment or poor nutritional state and those receiving anticoagulant or prolonged antibiotic therapy. Notify prescriber if PT decreases, and expect to give vitamin K.
- Assess for signs of superinfection, such as cough or sputum changes, diarrhea, drainage, fever, malaise, pain, perineal itching, rash, redness, and swelling.
- Watch for arthralgia, bleeding, ecchymosis, and pharyngitis (possible blood dyscrasia). Monitor PT and bleeding time.

## **PATIENT TEACHING**

- Tell patient to take ceftazidime exactly as prescribed.
- Tell patient to report evidence of blood dyscrasia or superinfection to prescriber immediately.
- Urge patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

# ceftibuten

**Cedax**

## Class and Category

*Pharmacologic class:* Third-generation cephalosporin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat acute bacterial exacerbations of chronic bronchitis caused by Haemophilus influenzae, or Moraxella catarrhalis, or Streptococcus pneumoniae; pharyngitis and tonsillitis caused by Streptococcus pyogenes; and acute bacterial otitis media caused by H. influenzae, M. catarrhalis, or S. pneumoniae*

## CAPSULES, ORAL SUSPENSION

**Adults and children 12 and over weighing more than 45 kg (99 lb).** 400 mg daily for 10 days. Oral suspension administered 2 hr before or 1 hr after a meal.

- *To treat pharyngitis and tonsillitis caused by S. pyogenes and acute bacterial otitis media caused by H. influenzae, M. catarrhalis, or S. pyogenes*

## ORAL SUSPENSION

**Children weighing 45 kg (99 lb) or less.** 9 mg/kg daily 2 hr before or 1 hr after a meal for 10 days. *Maximum:* 400 mg daily.

**DOSAGE ADJUSTMENT** Dosage reduced to 4.5 mg/kg (children weighing 45 kg [99 lb] or less) or 200 mg (adults and children weighing more than 45 kg [99 lb]) every 24 hr if creatinine clearance is 30 to 49 ml/min; dosage reduced to 2.25 mg/kg (children weighing 45 kg [99 lb] or less) or 100 mg (adults and children weighing more than 45 kg [99 lb]) every 24 hr if creatinine clearance is 5 to 29 ml/min. For patients receiving hemodialysis at least 2 times a week, a single dose of 9 mg/kg (children weighing 45 kg [99 lb] or less) or 400 mg (adult and children weighing more than 45 kg [99 lb]) given as oral suspension at end of each dialysis session.

## Mechanism of Action

Interferes with bacterial cell wall synthesis by inhibiting the cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die.

## Contraindications

Hypersensitivity to ceftibuten, other cephalosporins, or their components

## Interactions

### DRUGS

*aminoglycosides, loop diuretics*: Increased risk of nephrotoxicity

## Adverse Reactions

**CNS**: Aphasia, chills, fever, headache, psychosis, **seizures**

**CV:** Edema

**EENT:** Hearing loss, oral candidiasis

**GI:** Abdominal cramps, diarrhea, elevated liver enzymes, **hepatic failure**, hepatomegaly, jaundice, **melen**a, nausea, **pseudomembranous colitis**, vomiting

**GU:** Elevated BUN level, **nephrotoxicity**, **renal failure**, vaginal candidiasis

**HEME:** Eosinophilia, **hemolytic anemia**, **hypoprothrombinemia**, **neutropenia**, **thrombocytopenia**, **unusual bleeding**

**MS:** Arthralgia

**RESP:** Dyspnea

**SKIN:** Ecchymosis, erythema, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other:** **Anaphylaxis**, serum sickness, superinfection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Use ceftibuten cautiously in patients hypersensitive to penicillins because cross-sensitivity occurs in up to 10% of such patients.
- Obtain culture and sensitivity test results, if possible and as ordered, before giving drug.
- Refrigerate oral suspension; shake well before using. Discard after 14 days.
- Monitor BUN and serum creatinine levels to detect early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity.
- Be aware that an allergic reaction may occur a few days after therapy starts.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis.
- Assess for signs of superinfection, such as cough or sputum changes, diarrhea, drainage, fever, malaise, pain, perineal itching, rash, redness, and swelling.
- Assess for arthralgia, bleeding, ecchymosis, and pharyngitis; they may indicate a blood dyscrasia.

## PATIENT TEACHING

- Urge patient to complete the drug therapy as prescribed.
- Instruct patient to take drug on an empty stomach at least 2 hours before or 1 hour after meals.
- Inform patient that unflavored oral suspension has a bitter taste. Suggest having a flavor added when prescription is filled.
- Advise patient that buttermilk and yogurt can help maintain intestinal flora and decrease diarrhea during therapy.
- Tell patient to immediately report hypersensitivity reactions, severe diarrhea, and evidence of blood dyscrasia or superinfection.

# ceftriaxone sodium

## Class and Category

*Pharmacologic class:* Third-generation cephalosporin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat infections such as bacterial septicemia caused by Escherichia coli, Haemophilus influenzae, Klebsiella pneumoniae, Staphylococcus aureus, or Streptococcus pneumoniae; bone and joint infections caused by Enterobacter species, E. coli, K. pneumoniae, Proteus mirabilis, S. aureus, or S. pneumoniae; intra-abdominal infections caused by Bacteroides fragilis, Clostridium species, E. coli, K. pneumoniae, or Peptostreptococcus species; lower respiratory tract infections caused by Enterobacter aerogenes, E. coli, H. influenzae, H. parainfluenzae, K. pneumoniae, P. mirabilis, Serratia marcescens, S. aureus, or S. pneumoniae; pelvic inflammatory disease caused by Neisseria gonorrhoeae; skin and soft tissue infections caused by Acinetobacter calcoaceticus, B. fragilis, E. cloacae, E. coli, K. pneumoniae, K. oxytoca, Morganella morganii, Peptostreptococcus species, P. mirabilis, Pseudomonas aeruginosa, Serratia marcescens, S. aureus, S. epidermidis, S. pyogenes, or Viridans group streptococci; and urinary tract infections caused by E. coli, K. pneumoniae, M. morganii, P. mirabilis, or P. vulgaris*

## **I.V. INFUSION, I.M. INJECTION**

**Adults.** 1 to 2 g daily or in equally divided doses twice daily I.V. infusion given over 30 min. *Maximum:* 4 g daily.

**Children.** 50 to 75 mg/kg daily or in equally divided doses every 12 hr. I.V. infusion given over 30 min for children and 60 min for neonates. *Maximum:* 2 g daily.

- *To treat meningitis caused by H. influenzae, Neisseria meningitidis, or S. pneumoniae*

## **I.V. INFUSION**

**Adults.** 1 to 2 g infused over 30 min daily or in equally divided doses twice daily. *Maximum:* 4 g daily.

**Children.** *Initial:* 100 mg/kg infused over 30 min for children and 60 min for neonates on first day, then 100 mg/kg infused over 30 min for children and 60 min for neonates daily or in divided doses every 12 hr for 7 to 14 days. *Maximum:* 4 g daily.

- *To treat acute bacterial otitis media caused by H. influenzae, Moraxella catarrhalis, or S. pneumoniae*

## **I.M. INJECTION**

**Children.** 50 mg/kg as a single dose. *Maximum:* 1 g.

- *Adults and adolescents. 500 mg (cervical/urethral, pharyngeal, or rectal) caused by Neisseria gonorrhoeae*

## **I.M. INJECTION**

**Adults.** 250 mg as a single dose.

- *To provide surgical prophylaxis*

## **I.V. INFUSION**

**Adults.** 1 g given over 30 min, 30 min to 2 hr before surgery.

## **Mechanism of Action**

Interferes with bacterial cell wall synthesis by inhibiting cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die.

## **Incompatibilities**

Don't admix ceftriaxone with labetalol, pentamidine isethionate, or other antibiotics, such as aminoglycosides, because of potential for incompatibility, such as substantial mutual inactivation. Also don't mix with calcium-containing solutions or products because a ceftriaxone-calcium salt may precipitate in the kidneys and lungs and may be fatal, especially in newborns.

## **Contraindications**

Hyperbilirubinemic or premature neonates (up to a postmenstrual age of 41 weeks); hypersensitivity to ceftriaxone, other beta-lactam antibacterials or cephalosporins, penicillins, or their components; intravenous administration of ceftriaxone solutions containing lidocaine; neonates who are 28 days old or less if they're expected to need calcium-containing solutions, including parenteral nutrition.

## **Interactions**

### **DRUGS**

*aminoglycosides, loop diuretics*: Increased risk of nephrotoxicity

## Adverse Reactions

**CNS:** Chills, fever, headache, hypertonia, reversible hyperactivity, **seizures**

**CV:** Edema

**EENT:** Glossitis, hearing loss, stomatitis

**GI:** Abdominal cramps, cholestasis, ***Clostridium difficile-associated diarrhea***, diarrhea, elevated liver enzymes, gallbladder dysfunction, **hepatic failure**, **hepatitis**, hepatomegaly, nausea, oral candidiasis, **pancreatitis**, pseudolithiasis, **pseudomembranous colitis**, vomiting

**GU:** **Acute renal failure**, elevated BUN level, **nephrotoxicity**, oliguria, vaginal candidiasis, ureteric obstruction, urolithiasis

**HEME:** **Agranulocytosis**, **aplastic anemia**, eosinophilia, **hemolytic anemia**, **hemorrhage**, **hypoprothrombinemia**, **leukopenia**, **neutropenia**, **thrombocytopenia**

**MS:** Arthralgia

**RESP:** **Allergic pneumonitis**, dyspnea

**SKIN:** Allergic dermatitis, ecchymosis, erythema, **erythema multiforme**, exanthema, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**; drug fever; injection-site pain, redness, and swelling; serum sickness; superinfection

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

**WARNING** Be aware that calcium-containing products must not be given I.V. within 48 hours of ceftriaxone, including solutions given through a different I.V. line and at a different site, in neonates because a ceftriaxone-calcium salt may precipitate in the lungs and kidneys and could be fatal.

- Use ceftriaxone cautiously in patients who are hypersensitive to penicillins because cross-sensitivity has occurred in about 1% to 3% of such patients.

**WARNING** Ask patient if an allergic reaction was ever experienced when given other antibiotics. Patients who have had previous hypersensitivity reactions to carbapenems, other cephalosporins, penicillins, or other drugs may be at high risk for developing a serious reaction that may be fatal. Monitor all patients closely for a hypersensitivity reaction. If present, discontinue ceftriaxone immediately, notify prescriber,

and be prepared to provide emergency supportive care, as prescribed.

- Obtain culture and sensitivity results, if possible and as ordered, before giving drug.
- Protect powder from light.
- For I.V. use, reconstitute with an appropriate diluent, such as sterile water for injection or sodium chloride for injection, as follows: for 250-mg vial, add 2.4 ml; for 500-mg vial, add 4.8 ml; for 1-g vial, add 9.6 ml; and for 2-g vial, add 19.2 ml to yield 100 mg/ml. For piggyback bottles, reconstitute with 10 ml of diluent indicated above for 1-g bottle and 20 ml for 2-g bottle. After reconstitution, further dilute to 50 to 100 ml with diluent indicated above and infuse over 30 minutes. Never use a diluent that contains calcium, such as Ringer's solution or Hartmann's solution, because a precipitate can form and may be fatal if injected.

**WARNING** Never give ceftriaxone by I.V. infusion and calcium-containing I.V. solutions at the same time, including such continuous calcium-containing infusions as parenteral nutrition via Y-site. For patients other than neonates, ceftriaxone and calcium-containing solutions may be given sequentially if infusion lines are thoroughly flushed with a compatible fluid between infusions.

- For I.M. administration, reconstitute with an appropriate diluent, such as sterile water for injection or sodium chloride for injection, as follows: for 250-mg vial, add 0.9 ml; for 500-mg vial, add 1.8 ml; for 1-g vial, add 3.6 ml; and for 2-g vial, add 7.2 ml to make a 250-mg/ml concentration. Shake well. Inject deep into large muscle mass, such as the gluteus maximus.
- Know that lidocaine can be used instead of sterile water as a diluent to lessen the pain of an I.M injection of ceftriaxone (follow manufacturer instructions when doing so). However, be aware that local anesthetics such as lidocaine may cause methemoglobinemia as late as several hours after the injection. Monitor patient closely.
- Monitor BUN and serum creatinine levels to detect early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity. Also be alert for precipitates in the patient's urine, especially children. If any signs of renal dysfunction

occurs, notify prescriber, expect ceftriaxone to be discontinued, and provide supportive care, as prescribed.

- Assess ALT, AST, bilirubin, CBC, hematocrit, LD, and serum alkaline phosphatase levels during long-term therapy. If abnormalities occur, notify prescriber. Drug may have to be discontinued.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis caused by *C. difficile*. If diarrhea occurs, notify prescriber and expect to treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*. Ceftriaxone therapy may be withheld also.
- Monitor patient for evidence of gallbladder disease (abdominal pain, nausea, vomiting) because drug may cause ceftriaxone-calcium salt to deposit in the gallbladder, which may mimic gallstones. Expect drug to be discontinued if gallbladder disorders arise.
- Assess for signs of superinfection, such as cough or sputum changes, diarrhea, drainage, fever, malaise, pain, perineal itching, rash, redness, and swelling.
- Assess for arthralgia, bleeding, ecchymosis, and pharyngitis; they may indicate a blood dyscrasia.

## PATIENT TEACHING

- Tell patient to report evidence of blood dyscrasia or superinfection to prescriber immediately.
- Urge patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.
- Advise patient to report any hypersensitivity reactions, such as a rash, itching skin, or hives, to prescriber immediately and to stop taking the drug.
- Tell patient that if he received drug as an I.M. injection that used lidocaine as the diluent, he should watch for signs and symptoms such as fatigue; headache; light-headedness; skin color change of blue, gray, or pale; rapid heart rate; or shortness of breath. If present, patient should seek immediate medical attention.

**cefuroxime axetil**

**Ceftin**

**cefuroxime sodium**

**Zinacef**

## **Class and Category**

*Pharmacologic class:* Second-generation cephalosporin

*Therapeutic class:* Antibiotic

## **Indications and Dosages**

- *To treat pharyngitis and tonsillitis caused by Streptococcus pyogenes*

### **ORAL SUSPENSION (CEFTIN)**

**Adults, adolescents, and children ages 3 months to 12 years.** 10 mg/kg daily every 12 hr for 10 days. *Maximum:* 500 mg daily.

### **TABLETS (CEFTIN)**

**Adults and adolescents.** 250 mg every 12 hr for 10 days.

- *To treat acute otitis media caused by Haemophilus influenzae, Moraxella catarrhalis, Streptococcus pneumoniae, or S. pyogenes*

### **ORAL SUSPENSION (CEFTIN)**

**Children ages 3 months to 12 years.** 15 mg/kg every 12 hr for 10 days. *Maximum:* 1,000 mg daily.

## **TABLETS (CEFTIN)**

**Children under age 13 who can swallow tablets.** 250 mg every 12 hr for 10 days.

- *To treat impetigo caused by Staphylococcus aureus, or S. pyogenes*

## **ORAL SUSPENSION (CEFTIN)**

**Children ages 3 months to 12 years.** 15 mg/kg every 12 hr for 10 days. *Maximum: 1,000 mg daily.*

- *To treat acute bacterial maxillary sinusitis caused by H. influenzae or S. pneumoniae*

## **ORAL SUSPENSION (CEFTIN)**

**Children ages 3 months to 12 years.** 15 mg/kg every 12 hr for 10 days. *Maximum: 1,000 mg daily.*

## **TABLETS (CEFTIN)**

**Adults, adolescents, and children under age 13 who can swallow tablets.** 250 mg every 12 hr for 10 days.

- *To treat acute bacterial exacerbations of chronic bronchitis caused by H. influenzae, Haemophilus parainfluenzae, or S. pneumoniae (oral); lower respiratory tract infections including pneumonia caused by E. coli, H. influenzae, Klebsiella species, S. aureus, S. pneumoniae, or S. pyogenes (parenteral); uncomplicated skin and soft-tissue infections caused by S. aureus or S. pyogenes (oral) or Enterobacter species, E. coli, Klebsiella species, S. aureus, or S. pyogenes (parenteral)*

## **TABLETS (CEFTIN)**

**Adults and adolescents.** 250 to 500 mg twice daily (12 hr apart) for 10 days.

### **I.V. INFUSION, I.V. OR I.M. INJECTION (ZINACEF)**

**Adults.** 750 mg every 8 hr for 5 to 10 days. I.V. injection given over at least 3 to 5 min; I.V. infusion given intermittently over 15 to 60 min or as a continuous infusion.

- *To treat early Lyme disease caused by Borrelia burgdorferi*

### **TABLETS (CEFTIN)**

**Adults and adolescents.** 500 mg every 12 hr for 20 days.

- *To treat uncomplicated UTI caused by E. coli or Klebsiella pneumoniae*

### **TABLETS (CEFTIN)**

**Adults.** 250 mg every 12 hr for 7 to 10 days.

### **I.V. INFUSION, I.V. OR I.M. INJECTION**

**Adults.** 750 mg every 8 hr for 5 to 10 days. I.V. injection given over at least 3 to 5 min; I.V. infusion given intermittently over 15 to 60 min or as a continuous infusion.

- *To treat uncomplicated gonorrhea caused by Neisseria gonorrhoeae*

### **TABLETS (CEFTIN)**

**Adults.** 1 g as a single dose.

### **I.M. INJECTION (ZINACEF)**

**Adults.** 1.5 g as a single dose divided equally and injected into two different sites; given with oral probenecid 1 g.

- *To treat disseminated gonococcal infection and uncomplicated pneumonia caused by N. gonorrhoeae*

### **I.V. INFUSION, I.V. OR I.M. INJECTION (ZINACEF)**

**Adults.** 750 mg every 8 hr for 5 to 10 days. I.V. injection given over at least 3 to 5 min; I.V. infusion given intermittently over 15 to 60 min or as a continuous infusion.

- *To treat bone and joint infections caused by S. aureus*

### **I.V. INFUSION, I.V. OR I.M. INJECTION (ZINACEF)**

**Adults.** 1.5 g every 8 hr. I.V. injection given over at least 3 to 5 min; I.V. infusion given intermittently over 15 to 60 min or as a continuous infusion.

**Children over age 3 months.** 150 mg/kg daily in divided doses every 8 hr. I.V. injection given over at least 3 to 5 min; I.V. infusion given intermittently over 15 to 60 min or as a continuous infusion.

*Maximum:* Adult dose.

- *To treat bacterial meningitis caused by H. influenzae, Neisseria meningitidis, S. aureus, or S. pneumoniae*

### **I.V. INFUSION, I.V. INJECTION**

**Adults.** 1.5 to 3 g every 8 hr. I.V. injection given over at least 3 to 5 min; I.V. infusion given intermittently over 15 to 60 min or as a continuous infusion.

**Children over age 3 months.** 200 to 240 mg/kg/daily in divided doses every 6 to 8 hr. I.V. injection given over at least 3 to 5 min; I.V. infusion given intermittently over 15 to 60 min or as a continuous infusion.

- *To treat moderate infections other than those listed above*

## **I.V. INFUSION, I.V. OR I.M. INJECTION (ZINACEF)**

**Adults.** 750 mg every 8 hr for 5 to 10 days. I.V. injection given over at least 3 to 5 min; I.V. infusion given intermittently over 15 to 60 min or as a continuous infusion.

## **I.V. INFUSION OR INJECTION (ZINACEF)**

**Children over age 3 months.** 50 mg/kg daily in equally divided doses every 6 to 8 hr. I.V. injection given over 3 to 5 min; I.V. infusion given intermittently over 15 to 60 min or as a continuous infusion.

- *To treat severe or complicated infections other than those listed above*

## **I.V. INFUSION OR INJECTION (ZINACEF)**

**Adults.** 1.5 g every 8 hr. I.V. injection given over at least 3 to 5 min; I.V. infusion given intermittently over 15 to 60 min or as a continuous infusion.

**Children over age 3 months.** 100 mg/kg daily in equally divided doses every 6 to 8 hr. I.V. injection given over at least 3 to 5 min; I.V. infusion given intermittently over 15 to 60 min or as a continuous infusion.

- *To treat life-threatening infections other than those listed above*

## **I.V. INFUSION OR INJECTION (ZINACEF)**

**Adults.** 1.5 g every 6 hr. I.V. injection given over at least 3 to 5 min; I.V. infusion given intermittently over 15 to 60 min or as a continuous infusion.

- *To provide perioperative prophylaxis*

## **I.V. INJECTION (ZINACEF)**

**Adults.** 1.5 g, given over at least 3 to 5 min, 30 to 60 min before surgery (at induction of anesthesia for open-heart surgery), and then 0.75 g, given over at least 3 to 5 min, every 8 hr for prolonged procedures (1.5 g, given over at least 3 to 5 min, every 12 hr for total of 6 g with open-heart surgery).

***DOSAGE ADJUSTMENT*** Parenteral dosage reduced to 0.75 g every 12 hr if creatinine clearance is 10 to 20 ml/min or to 0.75 g every 24 hr if creatinine clearance less than 10 ml/min.

## **Mechanism of Action**

Interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands. Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die.

## **Incompatibilities**

Don't admix parenteral cefuroxime with other antibiotics, such as aminoglycosides, because of potential for incompatibility, such as substantial mutual inactivation. If they're administered concurrently, don't mix them in the same I.V. bag or bottle.

## **Contraindications**

Hypersensitivity to cefuroxime, other cephalosporins, or their components

# Interactions

## DRUGS

*aminoglycosides, loop diuretics:* Increased risk of nephrotoxicity

*antacids, histamine-2 antagonists, proton pump inhibitors:* Possibly lower bioavailability of oral cefuroxime

*oral combined estrogen-progesterone contraceptives:* Decreased effectiveness of oral contraceptive

## Adverse Reactions

**CNS:** Chills, fever, headache, **seizures**

**CV:** Edema

**EENT:** Hearing loss, oral candidiasis

**GI:** Abdominal cramps, diarrhea, elevated liver enzymes, **hepatic failure**, hepatomegaly, nausea, **pseudomembranous colitis**, vomiting

**GU:** Elevated BUN level, **nephrotoxicity**, **renal failure**, vaginal candidiasis

**HEME:** Eosinophilia, **hemolytic anemia**, **hypoprothrombinemia**, **neutropenia**, **thrombocytopenia**, **unusual bleeding**

**MS:** Arthralgia

**RESP:** Dyspnea

**SKIN:** Ecchymosis, erythema, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**

**Other:** **Anaphylaxis**; injection-site edema, pain, and redness; superinfection

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Use cefuroxime cautiously in patients hypersensitive to penicillin because cross-sensitivity has occurred in about 10% of such patients.
- Obtain culture and sensitivity results, if possible and as ordered, before giving drug.
- Give oral form with food to decrease GI distress, as needed.
- Remember that oral forms—tablets and suspension—aren't bioequivalent.
- For I.V. use, reconstitute using manufacturer's instructions according to type of preparation available. Solution ranges in color from light yellow to amber.
- For I.M. use, add 3 or 3.6 ml sterile water for injection to each 750-mg vial to yield 220 mg/ml.
- Thaw frozen parenteral solution at room temperature or under refrigeration before administration; make sure all ice crystals have melted. Don't force thawing by microwaving.
- Store reconstituted parenteral drug for up to 24 hours at room temperature or 96 hours in refrigerator. (Thawed solutions may be stable 24 hours at room temperature or 28 days if refrigerated.) Store reconstituted oral suspension in refrigerator or at room temperature up to 10 days.

- Give I.V. injection over 3 to 5 minutes through tubing of a flowing compatible I.V. fluid.
- Monitor I.V. site for extravasation and phlebitis.
- Monitor BUN and serum creatinine levels and fluid intake and output to detect signs of nephrotoxicity. Monitor patients with renal impairment closely because they may have greater toxic reactions to cefuroxime.
- Monitor patient for allergic reactions continuing up to a few days after therapy starts. Patients with a history of some form of allergy, especially to drugs, are at increased risk for an allergic reaction.
- Assess bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis. If it's suspected, stop drug, as ordered, and provide treatment as prescribed.
- Assess patient for arthralgia, bleeding, ecchymosis, and pharyngitis, which may indicate a blood dyscrasia.
- Monitor bleeding time and PT, as ordered. Be prepared to administer vitamin K, if ordered, to treat hypotherbinemia.

## PATIENT TEACHING

- Instruct patient to shake oral suspension well before measuring each dose and to use a calibrated liquid-measuring device.
- Advise patient using single-dose packets of oral suspension to empty contents of one packet into a glass and add at least 10 ml (2 tsp) of cold water; apple, grape, or orange juice; or lemonade. Tell him to stir well and consume entire mixture at once.
- Inform patient that buttermilk and yogurt help maintain intestinal flora and can decrease diarrhea during therapy.
- Instruct patient to report evidence of blood dyscrasia to prescriber immediately.
- Urge patient to report watery, bloody stools to prescriber immediately, even up to 2 months after drug therapy has ended.

**celecoxib**

# Celebrex

## Class and Category

*Pharmacologic class:* NSAID

*Therapeutic class:* Analgesic, anti-inflammatory, antirheumatic

## Indications and Dosages

- *To relieve signs and symptoms of osteo-arthritis*

### CAPSULES

**Adults.** 200 mg daily or 100 mg twice daily.

- *To relieve signs and symptoms of rheumatoid arthritis*

### CAPSULES

**Adults.** 100 to 200 mg twice daily.

- *To relieve signs and symptoms of juvenile rheumatoid arthritis*

### CAPSULES

**Children age 2 and over weighing more than 25 kg (55 lb).** 100 mg twice daily.

**Children age 2 and over weighing 10 to 25 kg (22 to 55 lb).** 50 mg twice daily.

- *To relieve pain from ankylosing spondylitis*

### CAPSULES

**Adults.** 200 mg daily or 100 mg twice daily. Dosage increased to 400 mg daily or 200 mg twice daily after 6 weeks if needed.

➤ *To manage acute pain, to treat primary dysmenorrhea*

## **CAPSULES**

**Adults.** 400 mg, followed by 200 mg if needed, on 1st day. On subsequent days, 200 mg twice daily as needed.

***DOSAGE ADJUSTMENT*** Daily dosage reduced by 50% for patients with moderate hepatic impairment. For patients who are poor CYP2C9 metabolizers, starting dosage should be half the lowest recommended dose.

## **Mechanism of Action**

Selectively inhibits the enzymatic activity of cyclooxygenase-2 (COX-2), the enzyme needed to convert arachidonic acid to prostaglandin. Prostaglandins are responsible for mediating the inflammatory response and causing local vasodilation, swelling, and pain. Prostaglandins also play a role in peripheral pain transmission to the spinal cord. By inhibiting COX-2 activity and prostaglandin production, this reduces inflammatory symptoms and relieves pain.

## **Contraindications**

Allergic reaction (such as anaphylaxis or angioedema) to aspirin, other NSAIDs, or sulfonamide derivatives or history of aspirin-induced nasal polyps with bronchospasm; hypersensitivity to celecoxib or its components; treatment of pain after coronary artery bypass graft surgery

## **Interactions**

## DRUGS

*ACE inhibitors, angiotensin II receptor antagonists, beta blockers:* Decreased antihypertensive effect of these drugs, increased risk of renal failure in patients who are elderly, have existing renal dysfunction, or are volume-depleted  
*anticoagulants such as warfarin, antiplatelet drugs such as aspirin and other salicylates, corticosteroids, selective serotonin reuptake inhibitors:* Increased risk of GI ulceration and other GI complications, increased risk of bleeding

*cyclosporine:* Increased risk of cyclosporine-induced nephrotoxicity

*CYP2C9 inducers such as rifampin:* Possibly decreased effectiveness of celecoxib

*CYP2C9 inhibitors such as fluconazole:* Possibly increased risk of celecoxib toxicity

*YP2D6 substrates:* Possibly enhance the exposure and toxicity of these drugs

*digoxin:* Increased risk of digitalis toxicity

*furosemide, thiazide diuretics:* Reduced diuretic effects of these drugs, increased risk of renal failure

*lithium:* Possibly elevated blood lithium level

*methotrexate:* Increased risk of methotrexate toxicity (neutropenia, renal dysfunction, thrombocytopenia)

*pemetrexed:* Increased risk of myelosuppression, GI and renal toxicity

## Adverse Reactions

**CNS:** Aseptic meningitis, cerebral hemorrhage, CVA, depression, dizziness, fever, headache, insomnia, suicidal ideation, syncope, transient ischemic attacks, vertigo

**CV:** Aortic valve incompetence, bradycardia, chest pain, congestive heart failure, deep vein thrombosis, fluid retention, hypertension, MI, palpitations, peripheral edema, tachycardia, thrombosis, unstable angina, vasculitis, ventricular fibrillation, ventricular hypertrophy

**EENT:** Conjunctival hemorrhage, deafness, labyrinthitis, nasopharyngitis, pharyngitis, rhinitis, sinusitis, vitreous floaters

**ENDO:** Hyperglycemia, hypoglycemia

**GI:** Abdominal pain, diarrhea, elevated liver enzymes, esophageal perforation, flatulence, GI bleeding or ulceration, hepatic failure, ileus, indigestion, jaundice, nausea, pancreatitis, perforation of intestines or stomach, vomiting

**GU:** Acute renal failure, interstitial nephritis, ovarian cyst, proteinuria, urinary incontinence, UTI

**HEME:** Agranulocytosis, aplastic anemia, decreased hematocrit and hemoglobin, leukopenia, pancytopenia, prolonged APTT, thrombocytopenia

**MS:** Arthralgia, back pain, elevated serum CK level, epicondylitis, tendon rupture

**RESP:** Bronchospasm, cough, dyspnea, pneumonia, pulmonary embolism, upper respiratory tract infection

**SKIN:** Erythema multiforme, exfoliative dermatitis, phototoxicity, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

**Other:** Anaphylaxis, angioedema, hyperkalemia, hypernatremia, hyponatremia, sepsis

# Childbearing Considerations

## PREGNANCY

- Drug increases risk of premature closure of the fetal ductus arterisus if given during the third trimester of pregnancy.
- Drug should be avoided in pregnant women starting at 30 weeks of gestation and onward.

## LACTATION

- Drug maybe present in breast milk in low concentrations.
- Patient should check with prescriber before breastfeeding.

## REPRODUCTION

- Drug may delay or prevent rupture of ovarian follicles, which may result in infertility that is reversible once drug therapy has been discontinued.
- Drug may need to be withheld in women who are having difficulty conceiving or who are being tested for infertility.

# Nursing Considerations

- Know that NSAIDs like celecoxib should be avoided in patients with a recent MI because risk of reinfarction increases with NSAID therapy. If therapy is unavoidable, monitor patient closely for signs of cardiac ischemia.
- Be aware that NSAIDs such as celecoxib should not be given to patients with severe heart failure because risk of heart failure increases with NSAID use. If use is unavoidable, monitor patient for worsening of heart failure.
- Use celecoxib with extreme caution in patients who have a history of GI bleeding or ulcer disease because NSAIDs, such as celecoxib, increase the risk of GI bleeding and ulceration. In these patients, drug should be used for shortest time possible.

- Be aware that serious GI tract ulceration and bleeding, as well as perforation of intestine or stomach, can occur without warning or symptoms. Debilitated or elderly patients are at greatest risk along with patients with a prior history of GI bleeding and/or peptic ulcer disease who used NSAIDs. Other patients who may be at risk include patients with advanced liver disease and/or coagulopathy, patients in poor health, smokers, use of certain drugs (antiplatelets, anticoagulants, oral corticosteroids, selective serotonin reuptake inhibitors), and use of alcohol. To minimize risk, give celecoxib with food. If patient develops GI distress, withhold celecoxib and notify prescriber immediately.
- Use celecoxib cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy because drug can start or worsen hypertension.
- Use celecoxib cautiously in children with systemic onset juvenile rheumatoid arthritis because serious adverse reactions can occur, including disseminated intravascular coagulation.
- Use celecoxib cautiously in patients known to be poor CYP2C9 metabolizers based on history or experience with other CYP2C9 substrates, such as phenytoin or warfarin. Dosage should start at half the lowest recommended amount. For patients with juvenile rheumatoid arthritis who are also poor CYP2C9 metabolizers, alternative management should be considered.

**WARNING** Know that use of NSAIDs like celecoxib increases risk of serious cardiovascular thrombotic events, including MI and stroke, which can be life-threatening. These events may occur early in treatment and risk increases with duration of use. Be aware that these events have occurred even in patients who do not have a history or known risk factors for cardiovascular disease. Monitor patient for warning signs such as chest pain, shortness of breath, slurring of speech, or weakness. If any signs and symptoms develop, withhold celecoxib, alert prescriber immediately, and provide supportive care, as prescribed.

**WARNING** Expect to monitor laboratory results (including WBC) and assess for infection in patient who has bone marrow suppression such as occurs with antineoplastic therapy because celecoxib's anti-inflammatory and

antipyretic actions may mask signs and symptoms, such as fever and pain.

- Monitor patient—especially if elderly or receiving long-term celecoxib therapy—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver enzymes because, in rare cases, elevation may progress to severe hepatic reaction, including fatal hepatitis, or hepatic failure or necrosis.
- Monitor BUN and serum creatinine levels in elderly patients; patients taking ACE inhibitors, angiotensin II receptor antagonists, or diuretics; and patients with heart failure, impaired hepatic dysfunction or renal function because drug may cause renal failure.
- Monitor CBC for decreased hemoglobin level and hematocrit because drug may worsen anemia.
- Assess patient's skin regularly for signs of rash or other hypersensitivity reaction because celecoxib is a sulfur drug and may cause serious skin reactions without warning, even in patients with no history of sensitivity to sulfur. At first sign of reaction, stop drug and notify prescriber.
- Avoid using celecoxib with a nonaspirin NSAID, regardless of the dose, because celecoxib reduces inflammation and fever, which may mask signs of infection.

## **PATIENT TEACHING**

- Instruct patient to swallow celecoxib capsules whole with a full glass of water and with food or milk to prevent stomach upset.
- Tell patient to take celecoxib exactly as prescribed and not to increase dosage or take drug longer than prescribed because serious adverse reactions can occur.
- Advise patient to notify prescriber if pain continues or is poorly controlled.
- Explain that celecoxib may increase the risk of serious adverse CV events; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, slurred speech, and weakness.

- Inform patient that the risk of congestive heart failure increases with NSAID use. Instruct patient to promptly report any evidence of edema, shortness of breath, or unexplained weight gain.
- Tell patient that celecoxib may increase the risk of serious adverse GI reactions. Stress the need to seek immediate medical attention if signs or symptoms develop, such as abdominal or epigastric, black or tarry stools, indigestion, and vomiting blood or material that resembles coffee grounds.
- Alert patient that celecoxib may cause serious skin reactions. Advise immediate medical attention if signs or symptoms develop, such as rash, blisters, fever, itching, or other evidence of hypersensitivity.
- Urge patient to avoid alcohol consumption and smoking during celecoxib therapy because they may increase the risk of adverse GI reactions.

## cenobamate

**Xcopri**

### Class and Category

*Pharmacologic class:* Sodium channel antagonist

*Therapeutic class:* Anticonvulsant

### Indications and Dosages

- *To treat partial-onset seizures as adjunct or monotherapy*

#### **TABLETS**

**Adults.** Initial: 12.5 mg once daily for 2 wk, then titrated as follows: 25 mg once daily for wk 3 and wk 4, 50 mg once daily for wk 5 and wk 6, 100 mg once daily for wk 7 and wk

8, and 150 mg once daily for wk 9 and wk 10. *Maintenance*: 200 mg once daily beginning wk 11. Dosage further increased in increments of 50 mg once daily every 2 wk, based on response and tolerability. *Maximum*: 400 mg once daily.

**DOSAGE ADJUSTMENT** For patients with mild to moderate hepatic impairment, maximum dosage 200 mg once daily.

## Mechanism of Action

May reduce repetitive neuronal firing by inhibiting voltage-gated sodium currents. It also is a positive allosteric modulator of the  $\gamma$ -aminobutyric acid (GABA<sub>A</sub>) ion channel.

## Contraindications

Familial short QT interval, hypersensitivity to cenobamate or its components

## Interactions

### DRUGS

*carbamazepine, CYP2B6 substrates, CYP3A substrates, lamotrigine, oral contraceptives*: Decreased plasma concentrations of these drugs, decreasing effectiveness

*clobazam, CYP2C19 substrates, phenobarbital, phenytoin*: Increased plasma concentrations of these drugs, increasing risk of adverse reactions

*CNS depressants*: Increased risk of neurological adverse reactions, including sedation and somnolence

*drugs that shorten QT interval*: Potential greater shortening of QT interval

## ACTIVITIES

*alcohol use:* Increased risk of neurological adverse reactions, including sedation and somnolence

## Adverse Reactions

**CNS:** Aphasia, asthenia, ataxia, balance disorder, confusion, dizziness, euphoric mood, fatigue, gait disturbance, irritability, headache, memory impairment, migraine, sedation, somnolence, **suicidal ideation**, tremor, vertigo

**CV:** Palpitations, **QT shortening**

**EENT:** Blurred vision, diplopia, dry mouth, nasopharyngitis, nystagmus, pharyngitis, taste distortion

**GI:** Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, elevated liver enzymes, nausea, vomiting

**GU:** Dysmenorrhea, pollakiuria, UTI

**MS:** Back pain, dysarthria, musculoskeletal chest pain

**RESP:** Dyspnea, hiccups

**SKIN:** Pruritus, rash

**Other:** Appendicitis, drug **reaction with eosinophilia and systemic symptoms (DRESS)/multiorgan hypersensitivity, hyperkalemia**, weight loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or visit <http://www.aedpregnancyregistry.org>.

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that cenobamate should not be given to patients with familial short QT syndrome because of risk of synergistic effect on the QT interval that would increase the risk of sudden death and ventricular arrhythmias.
- Use cenobamate cautiously in patients also receiving other medications known to shorten QT intervals, as a synergistic effect could occur.
- Maintain titration schedule, as rapid titration may cause adverse reactions that could be serious.

**WARNING** Monitor patient for signs and symptoms of **drug reaction with eosinophilia and systemic symptoms (DRESS)**, such as facial swelling, fever, lymphadenopathy, and rash, in addition to other organ system involvement such as hematological abnormalities, hepatitis, myocarditis, myositis, or nephritis. Eosinophilia is often present. Early manifestations such as fever or lymphadenopathy may be present without a rash. Notify prescriber immediately if suspected, as DRESS can be life-threatening. Expect cenobamate to be discontinued.

- Monitor patient for emergence of or worsening depression, suicidal thoughts or behavior, and/or any unusual changes in behavior or mood, because cenobamate increases risk of suicidal behavior and thoughts. Suicidal ideation has occurred as early as 1 week after starting drug therapy and can persist for duration of therapy.

- Discontinuing drug requires a gradual reduction over a period of at least 2 weeks, unless safety concerns require abrupt withdrawal.

## PATIENT TEACHING

- Tell patient to take tablets whole with liquid and not to chew or crush tablets. Let patient know that cenobamate can be taken with or without food.
- Instruct patient to notify prescriber of persistent, severe, or unusual signs and symptoms, especially if a fever or rash, along with other signs or symptoms, is present.
- Urge family or caregiver to monitor patient closely for suicidal tendencies, especially when therapy starts or dosage changes, and report any concerns to prescriber.
- Instruct patient to inform prescriber of all drugs taken, including over-the-counter and herbal preparations.
- Tell patient alcohol should be avoided while taking cenobamate.
- Advise women of childbearing age using oral contraceptives to use additional or an alternative nonhormonal contraceptive during cenobamate therapy. Cenobamate may reduce the efficacy of oral contraceptives.

**WARNING** Tell patient and family members to seek immediate emergency care if patient becomes unconscious or experiences prolonged palpitations.

- Urge patient to avoid hazardous activities until drug's CNS and visual effects are known.
- Counsel patient not to stop taking cenobamate abruptly, as drug must be gradually discontinued to minimize the potential for increased seizure frequency or other withdrawal effects.

# cephalexin hydrochloride

# cephalexin monohydrate

**Keflex**

## Class and Category

*Pharmacologic class:* First-generation cephalosporin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat bone infections caused by Proteus mirabilis or Staphylococcus aureus; genitourinary tract infections caused by Escherichia coli, Klebsiella pneumoniae, or P. mirabilis; respiratory infections caused by Streptococcus pneumoniae or S. pyogenes; and skin and skin structure infections caused by S. aureus or S. pyogenes*

### **CAPSULES, ORAL SUSPENSION, TABLETS**

**Adults and adolescents age 15 and over.** 250 mg every 6 hr or 500 mg every 12 hr for 7 to 14 days. *For severe infections:* Up to 4 g daily in 2 to 4 equally divided doses for 7 to 14 days.

**Children ages 1 to 15.** 25 to 50 mg/kg daily given in equally divided doses for 7 to 14 days. *For severe infections:* 50 to 100 mg/kg daily given in equally divided doses for 7 to 14 days.

- *To treat otitis media caused by Haemophilus influenzae, Moraxella catarrhalis, S. aureus, or S. pneumoniae*

## ORAL SUSPENSION

**Children.** 75 to 100 mg/kg daily in equally divided doses four times daily.

**DOSAGE ADJUSTMENT** For patients with a creatinine clearance of 30 to 59 ml/min, maximum dosage not to exceed 1 g; for creatinine clearance of 15 to 29 ml/min, dosage reduced to 250 mg every 8 or 12 hr; for creatinine clearance of 5 to 14 ml/min and patient not yet on dialysis, dosage reduced to 250 mg every 24 hr; and for creatinine clearance of 1 to 4 ml/min and patient not yet on dialysis, dosage reduced to 250 mg every 48 or 60 hr.

## Contraindications

Hypersensitivity to cephalixin, other cephalosporins, or their components

## Interactions

### DRUGS

*metformin*: Increased plasma metformin levels and increased risk of adverse reactions

*probenecid*: Increased and prolonged blood cephalixin level

## Adverse Reactions

**CNS:** Chills, fever, headache, **seizures**

**CV:** Edema

**EENT:** Hearing loss, oral candidiasis

**GI:** Abdominal cramps, diarrhea, elevated liver enzymes, **hepatic failure**, hepatomegaly, nausea,

**pseudomembranous colitis**, vomiting

**GU:** Elevated BUN level, **nephrotoxicity**, **renal failure**, vaginal candidiasis

## **Mechanism of Action**

Like all cephalosporins, cephalixin interferes with bacterial cell wall synthesis by inhibiting the final step in the cross-linking of peptidoglycan strands.

Peptidoglycan makes the cell membrane rigid and protective. Without it, bacterial cells rupture and die. This mechanism of action is most effective against bacteria that divide rapidly, including many gram-positive and gram-negative bacteria.

**HEME:** Eosinophilia, **hemolytic anemia**, **hypoprothrombinemia**, **neutropenia**, **thrombocytopenia**, **unusual bleeding**

**MS:** Arthralgia

**RESP:** Dyspnea

**SKIN:** Ecchymosis, erythema, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**

**Other:** **Anaphylaxis**, superinfection

## **Childbearing Considerations**

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cephalexin cautiously in patients hypersensitive to penicillin because cross-sensitivity occurs in about 10% of them.
- Obtain culture and sensitivity test results, if possible and as ordered, before giving drug.
- Monitor patient's BUN and serum creatinine levels to detect early signs of nephrotoxicity. Also monitor fluid intake and output; decreasing urine output may indicate nephrotoxicity. Expect to monitor a patient who already has renal impairment longer for nephrotoxicity, because drug clearance is slowed.
- Monitor for allergic reactions a few days after therapy starts.
- Assess ALT, AST, bilirubin, CBC, hematocrit, LD, and serum alkaline phosphatase, levels during long-term therapy.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold cefotaxime and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.
- Assess patient for arthralgia, bleeding, ecchymosis, and pharyngitis; they may indicate a blood dyscrasia.

## PATIENT TEACHING

- Advise patient to complete prescribed course of therapy.

- Instruct patient to shake oral suspension well before measuring each dose and to use a calibrated liquid-measuring device to ensure an accurate dose.
- Tell patient that buttermilk and yogurt can help maintain intestinal flora and decrease diarrhea during therapy.
- Urge patient to report watery, bloody stools to prescriber immediately, even if they occur up to 2 months after cephalexin therapy has ended.

## certolizumab pegol

**Cimzia**

### Class and Category

*Pharmacologic class:* Tumor necrosis factor (TNF) blocker

*Therapeutic class:* Immunomodulator, disease modifying antirheumatic drug (DMARD)

### Indications and Dosages

- *To reduce signs and symptoms of Crohn's disease and maintain clinical response in patients with moderately to severely active disease who have had an inadequate response to conventional therapy*

### SUBCUTANEOUS INJECTION

**Adults.** *Initial:* 400 mg (given as two 200-mg injections) and repeated at wk 2 and 4. *Maintenance:* 400 mg (given as two 200-mg injections) every 4 wk if clinical response occurs.

- *To treat active ankylosing spondylitis, active psoriatic arthritis, moderate to severe active rheumatoid arthritis or nonradiographic axial spondyloarthritis*

## SUBCUTANEOUS INJECTION

**Adults.** *Initial:* 400 mg (given as two 200-mg injections) and repeated at wk 2 and 4 followed by 200 mg every other week. *Maintenance:* 200 mg every other wk, or 400 mg (given as two 200-mg injections) every 4 wk if clinical response occurs.

- *To treat moderate to severe plaque psoriasis in patients who are candidates for phototherapy or systemic therapy*

## SUBCUTANEOUS INJECTION

**Adults.** 400 mg (given as two 200-mg injections) every other wk.

***DOSAGE ADJUSTMENT*** For patient with plaque psoriasis who weighs 90 kg (198 lb) or more, dosage may be changed to 400 mg (given as two 200-mg injections) and repeated at wk 2 and 4, followed by 200 mg every other week.

Route	Onset	Peak	Duration
SubQ	Unknown	54-171 hr	Unknown

## Mechanism of Action

Binds to human tumor necrosis factor (TNF) alpha, inhibiting it. TNF alpha stimulates production of inflammatory mediators, including interleukin-1, nitric oxide, platelet activating factor, and prostaglandins. TNF alpha level is increased in patients with Crohn's disease and rheumatoid arthritis. Inhibition of TNF alpha causes C-

reactive protein level to decline in patients with Crohn's disease, and the disease improves.

## Contraindications

Hypersensitivity to certolizumab or its components

## Interactions

### DRUGS

*abatacept, anakinra, natalizumab, rituximab*: Possibly increased risk of serious infection and neutropenia  
*immunosuppressants*: Possibly increased risk of infection  
*live-virus vaccines*: Increased risk of adverse vaccine effects

## Adverse Reactions

**CNS**: Anxiety, bipolar disorder, dizziness, fever, headache, malaise, **suicidal ideation**, syncope

**CV**: Angina, **arrhythmias**, **heart failure**, hypertension, **hypotension**, **MI**, **pericardial effusion**, **pericarditis**, peripheral edema, vasculitis

**EENT**: Optic neuritis, retinal hemorrhage, uveitis

**ENDO**: Hot flashes

**GI**: Abdominal pain, diarrhea, elevated liver enzymes, **hepatitis**, **intestinal obstruction**

**GU**: Menstrual dysfunction, **nephrotic syndrome**, pyelonephritis, **renal failure**, UTI

**HEME**: Anemia, **leukemia**, **leukopenia**, lymphadenopathy, **pancytopenia**, thrombophilia

**MS:** Arthralgia, extremity pain

**RESP:** Cough, dyspnea, pneumonia, upper respiratory infection

**SKIN:** Allergic dermatitis, alopecia, change of plaque psoriasis into a different psoriasis subtype, erythema multiforme, erythema nodosum, lichenoid skin reaction, melanoma, Merkel cell carcinoma, new or worsening psoriasis, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

**Other:** Anaphylaxis; angioedema; antibody formation to certolizumab; bacterial, invasive fungal, mycobacterial, parasitic, viral or other opportunistic infections including aspergillosis, blastomycosis, candidiasis, coccidioidomycosis, histoplasmosis, legionellosis, listeriosis, pneumocystosis, and tuberculosis; herpes infections; injection-site reactions (bruising, discoloration, pain, redness, swelling); lymphomas and other malignancies; lupus-like syndrome; sarcoidosis, serum sickness

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-877-311-8972 or <http://mothertobaby.org/pregnancy-studies/>.
- It is not known if drug can cause fetal harm although it may affect fetal immune responses.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Know that the safety of administering live or live-attenuated vaccines in neonates exposed to drug in utero is unknown.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that certolizumab should not be initiated in a patient with an active infection, including serious localized infections.
- Use certolizumab cautiously in patients with recurrent or increased risk of infection, patients who live in regions where histoplasmosis and tuberculosis are endemic, and patients with a history of CNS demyelinating disorders because any of these disorders can occur, rarely, during certolizumab therapy. Be aware that a falsely negative antigen and antibody test for histoplasmosis may occur in some patients during certolizumab therapy, even when an active infection is present. Patient should be monitored closely throughout therapy.
- Use cautiously in patients who are chronic carriers of hepatitis B virus because drug may reactivate the virus. Assess patient for evidence of hepatitis B viral infection before starting and periodically throughout certolizumab therapy. If HBV reactivation occurs, notify prescriber, stop drug, and start appropriate therapy, as ordered.
- Make sure patient has a tuberculin skin test before therapy starts. If skin test is positive (induration 5 mm or greater), treatment of latent tuberculosis must start before certolizumab is given, as prescribed. In addition, expect antituberculosis therapy to be given to a patient with a past history of latent or active tuberculosis in whom an adequate course of treatment cannot be confirmed, and for patients with a negative test for latent tuberculosis but having risk factors for tuberculosis infection. Be aware that a falsely negative test for latent tuberculosis may occur during certolizumab therapy, so any signs and symptoms suggestive of tuberculosis should be carefully evaluated.

**WARNING** Monitor all patients for infection during therapy, especially those who are at higher risk for infection, such as patients receiving immunosuppressants, those who are over 65 years of age, or who have comorbid conditions. If serious infection develops, expect prescriber to stop drug.

- Reconstitute two 200-mg certolizumab vials for each dose after drug has reached room temperature. Inject 1 ml sterile water for injection using a 20G needle into each vial. Gently swirl each vial without shaking. Continue swirling every 5 minutes as long as undissolved particles are observed, which may take as long as 30 minutes. Do not leave at room temperature, once reconstituted, for more than 2 hours before administration. If administration will be delayed, reconstituted drug can be refrigerated up to 24 hours. Do not let drug freeze.
- Administer drug only when solution has reached room temperature. Using a 20G needle, withdraw drug from vial using a separate syringe and needle for each vial. Switch to a 23G needle and administer subcutaneously into two separate areas on patient's abdomen or thigh.
- When using the prefilled syringe, know that the needle shield inside the removeable cap of the prefilled syringe contains a derivative of natural rubber latex, which may cause allergic reactions if touched by latex-sensitive persons.

**WARNING** Stop drug immediately and notify prescriber if patient has an allergic reaction. Expect to provide supportive care.

- Monitor patient closely for evidence of congestive heart failure (anxiety; crackles; dyspnea; sudden, unexplained weight gain), and notify prescriber if they occur.
- Monitor patient's CBC, as ordered, because certolizumab may have adverse hematologic effects. Notify prescriber about persistent bleeding, bruising, fever, or pallor.
- Be aware that certolizumab is a TNF inhibitor. Although rare, malignancies (especially lymphomas and leukemias) have been reported in patients receiving these drugs, including children. Patients with rheumatoid arthritis, especially those with very active disease, and patients with disorders that certolizumab treats are at greatest risk. Monitor these patients closely.
- Assess patient's skin regularly, especially for patients who are at risk for skin cancer, as drug may cause melanomas and Merkel cell carcinoma as well as other life-threatening disorders such as Stevens-Johnson syndrome. At the first sign of a rash, notify prescriber.

## **PATIENT TEACHING**

- Instruct patient on how to administer a subcutaneous injection using the prefilled syringe. Tell patient to keep drug in refrigerator until about 30 min before administering to allow it to warm up to room temperature. Caution him not to warm up the drug any other way. Check with patient about a latex allergy because the needle shield inside the removeable cap of the prefilled syringe contains a derivative of natural rubber latex, which may cause allergic reactions if touched by latex-sensitive persons. Tell him to inject the drug either into his abdomen or thigh and to make sure he injects the full amount. Review how to safely discard the needle and syringe after the injection.
- Inform the patient that he may receive vaccinations, except for live or live attenuated vaccines.
- Review signs and symptoms of allergic reaction (rash, swollen face, trouble breathing), and tell patient to seek emergency care immediately if these occur.
- Inform patient that injection-site reactions such as pain or redness may occur and usually are mild and transient. Instruct him to apply a towel soaked in cold water to the site if it hurts. Tell patient to call prescriber if reaction persists or worsens.
- Inform patient that drug may lower the ability of the immune system to fight infections. Tell patient to report any signs and symptoms of infection, including tuberculosis or reactivation of hepatitis B virus infections, that may occur during therapy. Instruct him to report fever, including a low-grade fever, persistent cough, or wasting or weight loss to prescriber.
- Tell patient to report evidence of bleeding disorders and infections to prescriber; drug may have to be stopped. Advise patient to avoid people with infections and to comply with all prescribed tests.
- Inform patient that certain kinds of cancer, especially leukemias and lymphomas are more likely in patients taking certolizumab but still rare. Emphasize need to keep follow-up visits and to report sudden or unusual signs or symptoms. Also advise patient to have periodic skin examinations, especially if they are at risk for skin cancer.
- Instruct patient to report lupus-like signs and symptoms that, although rare, may occur during therapy, such as chest pain that doesn't go away, joint pain, rash on cheeks or arms that's sensitive to the sun, or shortness of breath. Explain that drug may need to be discontinued if these occur.
- Advise patient to inform all healthcare providers about certolizumab use and to inform prescriber about any herbal remedies vitamin and mineral supplements, and OTC medications being taken.
- Advise patient to report any signs of new or worsening health issues such as autoimmune disorders, heart disease, or neurological disease,

especially bleeding, bruising, or a persistent fever.

- Tell women of childbearing age to notify prescriber if pregnancy occurs or is suspected, because drug's effects on the fetus are unknown. If pregnancy is confirmed, encourage patient to enroll in the pregnancy exposure registry by calling 1-877-311-8972. Also tell mothers wishing to breastfeed their infant to discuss breastfeeding with prescriber before doing so.

## cetirizine hydrochloride

**Quzyttir, Zyrtec**

### Class and Category

*Pharmacologic class:* Histamine-1 (H-1) receptor antagonist

*Therapeutic class:* Antihistamine

### Indications and Dosages

➤ *To treat acute urticaria*

#### **I.V. INJECTION (QUZYTIR)**

**Adults and adolescents age 12 and older.** 10 mg given over 1 to 2 min every 24 hr, as needed.

**Children age 6 to 11.** 5 or 10 mg, depending on severity, given over 1 to 2 min every 24 hr, as needed.

**Children 6 months to 5 years with normal hepatic and renal function.** 2.5 mg given over 1 to 2 min every 24 hr, as needed.

- *To treat chronic urticaria, perennial allergic rhinitis, or seasonal allergic rhinitis*

## **SYRUP, TABLETS (ZYRTEC)**

**Adults and children age 6 and older.** 5 or 10 mg once daily.

**Children age 2 to 5.** 2.5 mg once daily, increased to 5 mg once daily or 2.5 mg every 12 hr, if needed.

**Children age 1 to less than 2.** 2.5 mg once daily, increased to 2.5 mg every 12 hr.

**Infants age 6 months to 1 year.** 2.5 mg once daily.

## **Mechanism of Action**

The antihistaminic activity of cetirizine is mediated via selective inhibition of peripheral H<sub>1</sub>-receptors to alleviate urticaria.

## **Contraindications**

Hypersensitivity to cetirizine, hydroxyzine, levocetirizine, or their components

## **Interactions**

### **DRUGS**

*CNS depressants:* Increased CNS impairment

*theophylline:* Possibly decreased clearance of cetirizine, increasing plasma cetirizine levels

### **ACTIVITIES**

*alcohol use:* Increased CNS impairment

# Adverse Reactions

**CNS:** Dizziness, fatigue, feeling hot, headache, insomnia, irritability, paresthesia, presyncope, sedation, somnolence

**EENT:** Dry mouth, epistaxis, pharyngitis, taste alteration

**GI:** Abdominal pain, diarrhea, dyspepsia, nausea, vomiting

**RESP:** Bronchospasm, cough

**SKIN:** Diaphoresis

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug may be present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Know that Quzyttir is a single-use injectable product for intravenous administration only.
- Be aware that intravenous use is not recommended in children less than 6 years of age with impaired hepatic or renal function.
- Institute safety precautions, because drug can cause sedation and somnolence.

## PATIENT TEACHING

- Instruct patient to avoid hazardous activities until drug's CNS effects are known. Warn her that taking other CNS depressants, including over-the-counter products, increases sedation and somnolence.
- Warn patient not to drink alcohol while receiving cetirizine, because alcohol also increases sedation and somnolence.
- Keep oral drug out of reach of small children.

## chlordiazepoxide hydrochloride

**Librium**

### Class, Category, and Schedule

*Pharmacologic class:* Benzodiazepine

*Therapeutic class:* Anxiolytic

*Controlled substance schedule:* IV

### Indications and Dosages

- *To provide short-term management of mild to moderate anxiety*

#### **CAPSULES**

**Adults.** 5 to 10 mg three or four times daily.

**Children over age 6.** 5 mg two to four times daily, increased as needed to 10 mg two or three times daily.

- *To provide short-term management of severe anxiety*

#### **CAPSULES**

**Adults.** 20 to 25 mg three or four times daily.

- *To provide short-term treatment of acute alcohol withdrawal*

## **CAPSULES, I.V. OR I.M. INJECTION**

**Adults.** *Initial:* 50 to 100 mg, usually given I.V. or I.M. Repeated in 2 to 4 hr followed by individualized oral dosage if needed to control symptoms. I.V. given slowly no faster than 50 mg/min. *Maximum:* 300 mg daily.

- *To provide perioperative relaxation and reduce apprehension and anxiety*

## **CAPSULES, I.M. INJECTION**

**Adults.** 5 to 10 mg P.O. three or four times daily several days before surgery; 50 to 100 mg I.M. 1 hr before surgery.

***DOSAGE ADJUSTMENT*** Dosage reduced to 5 mg P.O. two to four times daily, as needed, for elderly or debilitated patients. For patients with a creatinine clearance less than 10 ml/min, dosage reduced by 50%.

## **Mechanism of Action**

May potentiate the effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptors in cortical and limbic areas of the CNS. By binding to these receptors, chlordiazepoxide increases GABA's inhibitory effects and blocks cortical and limbic arousal, which helps control emotional behavior. It also helps relieve symptoms of alcohol withdrawal by causing CNS depression.

## **Contraindications**

Hypersensitivity to chlordiazepoxide or its components

## Interactions

### DRUGS

*antacids*: Delayed absorption of chlordiazepoxide

*cimetidine, disulfiram*: Increased blood chlordiazepoxide level

*CNS depressants, opioids, other benzodiazepines, sedating antihistamines, tricyclic antidepressants*: Increased risk of sedation and somnolence and other CNS effects

*digoxin, phenytoin*: Increased blood level and risk of toxicity with digoxin and phenytoin

*levodopa*: Decreased efficacy of levodopa's antiparkinsonian effects

*opioids*: Increased risk of significant respiratory depression

### ACTIVITIES

*alcohol use*: Increased CNS effects, including severe respiratory depression and significant sedation and somnolence

*heavy smoking*: Reduced effectiveness of chlorodiazepoxide

## Adverse Reactions

**CNS**: Ataxia, confusion, depression, drowsiness, **suicidal ideation**

**CV**: **ECG changes, hypotension,**

**GI**: Elevated liver enzymes, **hepatic dysfunction**, jaundice

**HEME**: **Agranulocytosis**

**Other**: Injection-site pain, redness, and swelling

# Childbearing Considerations

## PREGNANCY

- Drug may increase risk of congenital malformations if used during the first trimester of pregnancy and may cause withdrawal symptoms and other adverse reactions in the neonate if given to mothers late in pregnancy.
- Drug is not recommended during pregnancy and should be discontinued if pregnancy occurs.

## LACTATION

- It is unknown if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

# Nursing Considerations

- Use chlordiazepoxide cautiously in patients with hepatic or renal impairment or porphyria.

**WARNING** Be aware that benzodiazepine therapy such as chlordiazepoxide should only be used concomitantly with opioid therapy in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of the opioid to be limited. Monitor patient closely for signs and symptoms of decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

**WARNING** Be aware that prolonged use of chlordiazepoxide at therapeutic doses can lead to dependence.

- For I.V. use, reconstitute ampule contents with 5 ml sterile water for injection or sodium chloride for injection. Agitate gently until completely dissolved. Give slowly over 1 minute.
- For I.M. use, reconstitute only with diluent provided by manufacturer.

**WARNING** Don't use supplied diluent to prepare drug for I.V. use because air bubbles form on the surface.

- Don't give opalescent or hazy solution.
- Monitor patient for evidence of phlebitis or thrombophlebitis after I.V. chlordiazepoxide administration.
- Monitor liver enzymes during therapy.
- Know that if patient is an aggressive, hyperactive child or has a history of psychiatric disorders, watch for paradoxical reactions, such as acute rage excitement, and stimulation, during first 2 weeks of therapy.
- Watch patients closely (especially children, adolescents, and young adults) for suicidal tendencies, particularly when chlordiazepoxide therapy starts and dosage changes.

## PATIENT TEACHING

- Warn that drug may cause drowsiness.

**WARNING** Warn patient not to consume alcohol or take an opioid during chlordiazepoxide therapy without prescriber knowledge, as severe respiratory depression can occur that may lead to death.

**WARNING** Inform patient about potentially fatal additive effects of combining a benzodiazepine like chlordiazepoxide with an opioid. Instruct patient to inform all prescribers of chlordiazepoxide use, especially if pain medication may be prescribed.

- Advise patient to avoid other CNS depressants during therapy.
- Warn patient not to take antacids with chlordiazepoxide.

- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.

**chlorothiazide**

**Diuril**

**chlorothiazide sodium**

**Diuril**

## **Class and Category**

*Pharmacologic class:* Thiazide diuretic

*Therapeutic class:* Antihypertensive, diuretic

## **Indications and Dosages**

➤ *To treat hypertension*

### **ORAL SUSPENSION, TABLETS**

**Adults.** 500 to 1,000 mg daily in a single dose or divided doses twice daily. *Maximum:* 2,000 mg daily in divided doses.

**Children age 6 months and over.** 10 to 20 mg/kg daily in a single dose or divided doses twice daily. *Maximum:* 1,000 mg daily for ages 2 to 12; 375 mg daily for ages 6 months to 2 years.

**Children under age 6 months.** Up to 30 mg/kg daily in divided doses given twice daily.

- *As adjunct therapy to treat edema associated with corticosteroid and estrogen therapy, congestive heart failure, hepatic cirrhosis, and renal dysfunction*

## ORAL SUSPENSION, TABLETS

**Adults.** 500 to 1,000 mg once or twice a day. Administered on an intermittent schedule, if needed, such as alternate days or 3 to 5 days/wk.

**Children age 6 months and over.** 10 to 20 mg/kg daily in a single dose or divided doses twice daily. *Maximum:* 1,000 mg daily for children ages 2 to 12; 375 mg daily for children ages 6 months to 2 years.

**Children under age 6 months.** Up to 30 mg/kg daily in divided doses twice daily.

## I.V. INFUSION OR INJECTION

**Adults.** 500 mg to 1 g given slowly over at least 5 min for I.V. injection and 30 min for I.V. infusion once or twice daily.

Route	Onset	Peak	Duration
P.O.	2 hr	4 hr	6-12 hr
I.V.	15 min	4 hr	6-12 hr

## Mechanism of Action

May promote chloride, sodium, and water excretion by inhibiting sodium reabsorption in the kidneys' distal tubules. Initially, chlorothiazide may reduce blood pressure by decreasing cardiac output, extracellular fluid volume, and plasma volume. It also may dilate arteries directly, reducing peripheral vascular resistance. After several weeks, cardiac output, extracellular fluid and plasma

volume return to normal, but peripheral vascular resistance remains decreased.

## Contraindications

Hypersensitivity to chlorothiazide, sulfonamides, or their components

## Interactions

### DRUGS

*ACTH, corticosteroids:* Intensified electrolyte depletion, especially potassium

*angiotensin II antagonist or angiotensin converting enzyme inhibitor in combination with NSAIDs:* Increased risk of renal dysfunction in patients with compromised renal function, especially the elderly or patients who are volume-depleted

*barbiturates, narcotics:* Possibly increased risk of orthostatic hypotension

*cholestyramine, colestipol:* Decreased chlorothiazide absorption

*insulin, oral hypoglycemics:* Possible alteration in blood glucose control

*lithium:* Increased risk of lithium toxicity

*nondepolarizing skeletal muscle relaxants:* Possibly increased effects of muscle relaxants

*NSAIDs:* Possibly reduced diuretic effect of chlorothiazide

*other antihypertensives:* Increased antihypertensive effect

### ACTIVITIES

*alcohol:* Increased risk of orthostatic hypotension

# Adverse Reactions

**CNS:** Dizziness, headache, paresthesia, restlessness, vertigo, weakness

**CV:** Orthostatic hypotension

**ENDO:** Hyperglycemia

**GI:** Abdominal cramps, anorexia, constipation, diarrhea, gastric irritation, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Glycosuria, hematuria (I.V. form), impotence, interstitial nephritis, renal dysfunction, **renal failure**

**HEME:** **Agranulocytosis, aplastic anemia, hemolytic anemia, leukopenia, thrombocytopenia**

**MS:** Muscle spasms

**SKIN:** Photosensitivity, purpura, rash, urticaria

**Other:** **Anaphylactic reactions, hypercalcemia, hyperuricemia, hypochloremic alkalosis, hypokalemia, hypomagnesemia, hyponatremia, hypovolemia**

# Childbearing Considerations

## PREGNANCY

- Drug may cause fetal or neonatal harm such as jaundice, thrombocytopenia, and possibly other adverse reactions as it does cross the placental barrier.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is unknown if drug is present in breast milk.

- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## **Nursing Considerations**

- Don't give parenteral form of chlorothiazide by I.M. or subcutaneous route.
- For I.V. use, reconstitute with at least 18 ml of sterile water for injection. Discard unused solution after 24 hours. Reconstituted solution is compatible with dextrose solution or normal saline solution for infusion.
- Watch I.V. site closely. If extravasation occurs, stop infusion and tell prescriber at once.
- Weigh patient daily to assess fluid loss and drug effectiveness. If used to treat hypertension, check blood pressure often; antihypertensive effect may not appear for days.
- Assess patient for electrolyte imbalances.
- Monitor renal function closely, especially in elderly patients, because risk of toxicity increases with renal impairment.

## **PATIENT TEACHING**

- Tell patient to take chlorothiazide early in the day to avoid nocturia and to take it with food or milk if GI distress occurs.
- Urge patient to eat a high-potassium diet.
- Instruct patient to rise slowly to minimize effects of orthostatic hypotension.
- Urge patient to weigh himself at least weekly and to notify prescriber if weight rises or falls by 5 lb (2.25 kg) or more in 2 days.
- Tell patient to immediately notify prescriber if he develops cramps, diarrhea, dizziness, drowsiness, excessive thirst, increased heart rate, nausea, restlessness, sudden joint pain, tiredness, vomiting, or weakness.
- Know that if patient has diabetes mellitus, tell him to check blood glucose level often. Insulin or oral antidiabetic dosage may have to be increased.
- Tell patient to avoid prolonged exposure to sun, use sunscreen, and wear protective clothing.

- Advise patient to consult prescriber or pharmacist before using alcohol and such OTC drugs as those used for appetite control, colds, cough, hay fever, and sinus problems.

**chlorpromazine**

**chlorpromazine  
hydrochloride**

## **Class and Category**

*Pharmacologic class:* Phenothiazine

*Therapeutic class:* Antiemetic, antipsychotic, tranquilizer

## **Indications and Dosages**

- *To manage symptoms of psychotic disorders or control manic manifestations of manic-depression in outpatients*

### **E.R. CAPSULES**

**Adults.** 30 to 300 mg 1 to 3 times daily, with dosage adjusted as needed. *Maximum:* 1 g daily.

### **TABLETS**

**Adults.** 30 to 75 mg/day divided equally into 2 to 4 doses, increased as needed. *Usual maintenance:* 200 mg/day. *Maximum:* 800 mg/day.

- *To control acutely disturbed or manic hospitalized patients*

## **I.M. INJECTION**

**Adults.** 25 mg. 25 to 50 mg repeated in 1 to 4 hr, if needed. Increased gradually over several days up to 400 mg every 4 to 6 hr for severe cases until behavior is controlled. Then, regimen switched to oral form and outpatient dosage.

- *To treat severe behavioral problems in children*

## **TABLETS**

**Children ages 6 months to 12 years.** 0.55 mg/kg every 4 to 6 hr, as needed.

## **SUPPOSITORIES**

**Children ages 6 months to 12 years.** 1 mg/kg every 6 to 8 hr, as needed.

## **I.M. INJECTION**

**Children ages 6 months to 12 years.** 0.55 mg/kg every 6 to 8 hr. *Maximum:* 75 mg daily for children ages 5 to 12 years or weighing 23 to 45 kg (50.6 to 99 lb) except in unmanageable cases; 40 mg daily for children up to age 5 or weighing up to 23 kg (50.6 lb).

- *To treat nausea and vomiting*

## **TABLETS**

**Adults and adolescents.** 10 to 25 mg every 4 to 6 hr, as needed.

**Children ages 6 months to 12 years.** 0.5 to 1 mg/kg every 4 to 6 hr, as needed.

## **I.M. OR I.V. INJECTION**

**Adults.** 25 mg. If no hypotension occurs, 25 to 50 mg every 4 to 6 hr, as needed, until vomiting stops; then drug switched to oral form. I.V. injection given no more than 1 mg/min.

**Children age 6 months and over.** 0.5 to 1 mg/kg every 6 to 8 hr, as needed. I.V. injection given no more than 0.5 mg/min. *Maximum:* 75 mg daily for children ages 5 to 12 or weighing 23 to 45 kg (50.6 to 99 lb); 40 mg daily for children up to age 5 or weighing up to 23 kg (50.5 lb).

## **SUPPOSITORIES**

**Adults and adolescents.** 50 to 100 mg every 6 to 8 hr, as needed.

**Children ages 6 months to 12 years.** 1 mg/kg every 6 to 8 hr, as needed.

➤ *To treat intractable hiccups*

## **TABLETS**

**Adults.** 25 to 50 mg three times daily or four times daily. If hiccups last longer than 2 to 3 days, route switched to I.M., as prescribed.

## **I.M. INJECTION**

**Adults.** 25 to 50 mg every 3 to 4 hr, as needed, given only if oral route is ineffective. If symptoms persist, route switched to I.V., as prescribed.

## **I.V. INFUSION**

**Adults.** 25 to 50 mg diluted in 500 to 1,000 ml of normal saline solution and administered slowly with patient supine.

➤ *To provide preoperative relaxation*

## TABLETS

**Adults and adolescents.** 25 to 50 mg 2 to 3 hr before surgery.

**Children ages 6 months to 12 years.** 0.55 mg/kg 2 to 3 hr before surgery.

## I.M. INJECTION

**Adults.** 12.5 to 25 mg 1 to 2 hr before surgery.

**Children age 6 months and over.** 0.55 mg/kg 1 to 2 hr before surgery.

➤ *To provide intraoperative sedation*

## I.V. INJECTION

**Adults.** 25 mg diluted to 1 mg/ml with sodium chloride for injection and given at no more than 1 mg/min. *Maximum:* 25 mg.

**Children age 6 months and over.** 1 mg/ml and given at no more than 0.5 mg/min. to maximum dose, as needed. May repeat regimen in 30 min, if needed. *Maximum:* 0.25 mg/kg

## I.M. INJECTION

**Adults.** 12.5 mg. Repeated in 30 min if needed and no hypotension occurs.

**Children age 6 months and over.** 0.25 mg/kg. Repeated in 30 min if needed and tolerated.

➤ *To treat acute intermittent porphyria*

## TABLETS

**Adults and adolescents.** 25 to 50 mg three times daily or four times daily.

## I.M. INJECTION

**Adults.** 25 mg three times daily or four times daily until oral route is possible.

➤ *As adjunct to treat tetanus (usually with barbiturates)*

## I.V. INJECTION

**Adults.** 25 to 50 mg diluted to at least 1 mg/ml and given at no more than 1 mg/min every 6 to 8 hr.

**Children age 6 months and over.** 0.55 mg/kg every 6 to 8 hr, diluted to at least 1 mg/ml and given at no more than 0.5 mg/min. *Maximum:* 75 mg daily for children ages 5 to 12 years or weighing 23 to 45 kg (50.5 lb to 99 lb); 40 mg daily for children up to age 5 years or weighing up to 45 kg (50.6 lb).

## I.M. INJECTION

**Adults.** 25 to 50 mg three times daily or four times daily.

**Children age 6 months and over.** 0.55 mg/kg every 6 to 8 hr. *Maximum:* 75 mg daily for children ages 5 to 12 or weighing 23 to 45 kg (50.6 to 99 lb); 40 mg daily for children up to age 5 years or weighing up to 23 kg (50.6 lb).

***DOSAGE ADJUSTMENT*** Dosage possibly reduced for patients with hepatic dysfunction. Dosage reduced to one-third to one-half the normal adult dosage for elderly or debilitated patients.

## Mechanism of Action

Depresses brain areas that control activity and aggression, including the cerebral cortex, hypothalamus, and limbic system, by an unknown mechanism. Prevents nausea and vomiting by inhibiting or blocking dopamine receptors in

the medullary chemoreceptor trigger zone and peripherally by blocking the vagus nerve in the GI tract. May relieve anxiety by indirect reduction in arousal and increased filtering of internal stimuli to the reticular activating system in the brain stem.

## **Incompatibilities**

Don't mix chlorpromazine with atropine, thiopental, or solutions that don't have a pH of 4 to 5 because a precipitate will form. Don't mix chlorpromazine injection with other drugs in a syringe.

## **Contraindications**

Comatose states; hypersensitivity to chlorpromazine, phenothiazines, or their components; use of large amounts of CNS depressants

## **Interactions**

### **DRUGS**

*anticonvulsants*: Possibly lowered convulsive threshold

*CNS depressants such as anesthetics, barbiturates,*

*narcotics*: Prolonged and intensified CNS depression

*metrizamide*: Possibly lowered seizure threshold

*oral anticoagulants*: Decreased anti-coagulation

*propranolol*: Increased plasma levels of both drugs

*thiazide diuretics*: Possibly increased orthostatic hypotension

### **ACTIVITIES**

*alcohol use*: Prolonged and intensified CNS depression

# Adverse Reactions

**CNS:** Drowsiness, extrapyramidal reactions (such as dystonia, fever, motor restlessness, pseudoparkinsonism, and tardive dyskinesia), **neuroleptic malignant syndrome, seizures**

**CV:** ECG changes, such as nonspecific, usually reversible Q- and T-wave changes; orthostatic hypotension; tachycardia

**EENT:** Blurred vision, dry mouth, nasal congestion, ocular changes (fine particle deposits in lens and cornea) with long-term therapy

**ENDO:** Gynecomastia, hyperglycemia, **hypoglycemia**, lactation, moderate breast engorgement

**GI:** Constipation, ileus, nausea

**GU:** Amenorrhea, ejaculation disorders, impotence, priapism, urine retention

**HEME:** **Agranulocytosis, aplastic anemia**, eosinophilia, **hemolytic anemia, leukopenia, pancytopenia, thrombocytopenic purpura**

**SKIN:** **Exfoliative dermatitis**, photosensitivity, tissue necrosis, urticaria

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Extrapyramidal and/or withdrawal symptoms have occurred in neonates exposed to phenothiazines during the third trimester of pregnancy.
- Drug should not be used in pregnant women or those likely to become pregnant, unless the expected benefit to the mother outweighs the

potential risk to the fetus.

## **LACTATION**

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## **Nursing Considerations**

- Don't open or crush E.R. capsules.
- Know that chlorpromazine shouldn't be used to treat dementia-related psychosis in the elderly because of an increased risk of death.
- Use chlorpromazine cautiously in patients (especially children) with chronic respiratory disorders (such as severe asthma or emphysema) or acute respiratory tract infections because drug has CNS depressant effect. Also use cautiously in patients with cardiovascular, hepatic, or renal disease because of increased risk of developing arrhythmias, heart failure, and hypotension.
- Know that because of chlorpromazine's anticholinergic effects, use it cautiously in patients with glaucoma. Also use it cautiously in those who are exposed to extreme heat or organophosphate insecticides and those receiving atropine or related drugs.
- Protect concentrate from light. Refrigeration isn't required.
- Dilute concentrate in at least 60 ml of diluent just before administering it. Use a carbonated beverage, coffee, milk, orange syrup, pudding and soup, semisolid food, simple syrup, tea, tomato or fruit juice, or water.
- Protect parenteral solution from light. Solution should be clear and colorless to pale yellow. Discard markedly discolored solution.
- Don't inject drug by subcutaneous route because it can cause severe tissue necrosis.
- Wear gloves when working with liquid or injectable form because parenteral solution may cause contact dermatitis.
- For I.V. injection, dilute chlorpromazine with sodium chloride to a concentration of 1 mg/ml.

- Give I.M. injection slowly and deep into upper outer quadrant of buttocks, such as in the gluteus maximus. To minimize hypotensive effects, keep patient lying flat and monitor blood pressure for 30 minutes after injection.

**WARNING** Stay alert for possible suppressed cough reflex, which increases the risk of the patient's aspirating vomitus.

- Monitor patient for increased sensitivity to drug's CNS effects if patient has a history of hepatic encephalopathy from cirrhosis.

**WARNING** Notify prescriber immediately if neuroleptic malignant syndrome (altered mental status, autonomic instability hyperpyrexia, muscle rigidity) develops, and expect to stop drug and start intensive treatment. Watch for recurrence if patient resumes antipsychotic therapy.

## PATIENT TEACHING

- Instruct patient to swallow E.R. capsules whole and not to crush, break, or chew them.
- Tell patient not to take drug within 2 hours of an antacid. Allow him to take drug with food or a full glass of milk or water.
- Tell patient using suppository form to chill the suppository, moisten it with cold water, and insert it well into rectum.
- Tell patient to store oral concentrate at room temperature, away from light, to measure it with the dropper provided, and to dilute it in 4 ounces of fluid just before use.
- Know that because of possible blurred vision, dizziness, and drowsiness (especially during the first few days of therapy), advise patient to avoid hazardous activities until drug's CNS effects are known.
- Tell patient to avoid alcohol because of possible additive effects and hypotension.
- Advise patient, especially if elderly, to rise slowly from a supine or seated position to avoid dizziness, fainting, and light-headedness.

- Tell patient to inform doctors and dentists that he's taking chlorpromazine before he has dental work, medical tests, or surgery.
- Explain that drug may reduce the body's response to cold and heat; tell patient to avoid temperature extremes, as in a hot tub, sauna, or very cold or hot shower. Remind patient to dress warmly in cold weather.
- Warn patient not to take OTC drugs for an allergy or a cold because they can increase the risk of heatstroke and other unwanted effects.
- Inform patient that drug increases sensitivity to sunlight; tell him to stay out of the sun as much as possible and to protect his skin.
- Suggest fluids, hard candy, or sugarless gum for patient who is experiencing a dry mouth.
- Urge patient to report sudden sore throat or other signs of infection.
- Advise female patient of childbearing age to notify prescriber if she intends to become or suspects that she is pregnant during therapy.

## chlorthalidone

### Hygroton, Thalitone, Uridon (CAN)

## Class and Category

*Pharmacologic class:* Thiazide-like diuretic

*Therapeutic class:* Antihypertensive, diuretic

## Indications and Dosages

- *As adjunct to reduce edema caused by heart failure, corticosteroid or estrogen therapy, hepatic cirrhosis, or renal dysfunction, including nephrotic syndrome*

## TABLETS

**Adults.** *Initial:* 50 to 100 mg (Thalitone, 30 to 60 mg) daily, 100 mg (Thalitone, 60 mg) every other day, or 150 to 200 mg (Thalitone, 90 to 120 mg) daily or every other day.

*Maintenance:* Individualized; may be lower than initial dosage.

➤ *To treat hypertension*

## TABLETS

**Adults.** *Initial:* 12.5 to 25 mg daily (Thalitone, 15 mg daily). If response is insufficient, dosage increased to 50 mg daily (Thalitone, 30 mg daily). If additional control is required, dosage increased to 100 mg daily (Thalitone 45 to 50 mg daily) or a second antihypertensive added.

*Maintenance:* Individualized; may be lower than initial dosage.

Route	Onset	Peak	Duration
P.O.	2-3 hr	2-6 hr	24-72 hr

## Mechanism of Action

May promote chloride, sodium, and water excretion by inhibiting sodium reabsorption in the distal tubules of the kidneys. Initially, chlorthalidone may decrease cardiac output, extracellular fluid volume, and plasma volume, which helps explain how it reduces blood pressure. It may also dilate arteries directly, which helps reduce peripheral vascular resistance and blood pressure. After several weeks, cardiac output, extracellular fluid, and plasma volume return to normal, but peripheral vascular resistance remains decreased.

## Contraindications

Anuria; hypersensitivity to chlorthalidone, other sulfonamides, or their components

## Interactions

### DRUGS

*antihypertensives*: Potentiated action of antihypertensives and chlorthalidone

*insulin, oral hypoglycemics*: Possibly altered blood glucose control

*lithium*: Decreased renal lithium clearance and increased risk of lithium toxicity

*loop diuretics*: Increased synergistic effects, resulting in profound diuresis and serious electrolyte imbalances

*tubocurine*: Increased response to tubocurine

## Adverse Reactions

**CNS**: Dizziness, headache, insomnia, light-headedness, paresthesia, restlessness, vertigo, weakness

**CV**: Orthostatic hypotension, vasculitis

**EENT**: Yellow vision

**ENDO**: Hyperglycemia

**GI**: Abdominal cramps or pain, anorexia, bloating, constipation, diarrhea, gastric irritation, nausea, **pancreatitis**, vomiting

**GU**: Decreased libido, impotence

**HEME**: **Agranulocytosis, aplastic anemia, hypoplastic anemia, leukopenia, thrombocytopenia**

**MS**: Gout attacks, muscle spasms

**SKIN:** Cutaneous vasculitis, **exfoliative dermatitis**, necrotizing vasculitis, photosensitivity, purpura, rash, urticaria

**Other:** Hyperuricemia

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal or neonatal harm such as electrolyte imbalances, hypoglycemia, jaundice, thrombocytopenia, and possibly other adverse reactions as it does cross the placental barrier.
- Drug should not be used as first-line therapy to treat hypertension in pregnant women.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## Nursing Considerations

- Use chlorthalidone cautiously in patients with impaired hepatic function or progressive hepatic disease because minor changes in fluid and electrolyte balance may cause hepatic coma.
- Assess blood glucose levels, BUN, serum electrolyte, and uric acid levels before therapy and periodically throughout therapy. Monitor patient for signs of fluid and electrolyte imbalance.

**WARNING** Monitor renal function periodically to detect cumulative drug effects, which may cause azotemia in patients with impaired renal function.

## PATIENT TEACHING

- Stress the importance of taking chlorthalidone even when feeling well.
- Tell patient to store drug at room temperature in tightly closed container.
- Tell patient to take drug in the morning with food or milk.
- Instruct patient to rise slowly from a seated or lying position to minimize effects of orthostatic hypotension.
- Advise patient to check blood pressure regularly.
- Instruct patient to report signs of low potassium level, such as fatigue and muscle weakness.
- Advise patient to protect his skin from the sun.
- Urge patient to immediately report sudden joint pain to prescriber because drug can cause sudden gout attacks.
- Instruct patient to take a missed dose as soon as he remembers it. If he misses one day in an every-other-day schedule, tell him to take the dose on the off day and then resume usual dosing schedule. Warn against taking double or extra doses.

**chlorzoxazone**

**Lorzone**

## Class and Category

*Pharmacologic class:* Benzoxazole derivative

*Therapeutic class:* Skeletal muscle relaxant

## Indications and Dosages

- *As adjunct to relieve acute discomfort associated with painful musculoskeletal conditions*

## **TABLETS**

**Adults.** *Initial:* 375 mg to 500 mg three or four times daily, decreased or increased according to response. *Maximum:* 750 mg three or four times daily.

Route	Onset	Peak	Duration
P.O.	In 1 hr	Unknown	3–4 hr

## **Mechanism of Action**

Reduces muscle spasm by inhibiting multisynaptic reflex arcs at the level of the spinal cord and subcortical areas of the brain that are active in producing and maintaining skeletal muscle spasm.

## **Contraindications**

Hypersensitivity to chlorzoxazone or any of its components

## **Interactions**

### **DRUGS**

*CNS depressants:* Additive CNS depression

### **ACTIVITIES**

*alcohol use:* Additive CNS depression

## **Adverse Reactions**

**CNS:** Dizziness, drowsiness, headache, light-headedness, malaise, paradoxical stimulation

**GI:** Abdominal cramps or pain, constipation, diarrhea, **GI bleeding**, heartburn, **hepatotoxicity**, nausea, vomiting

**GU:** Urine discoloration

**HEME:** **Agranulocytosis**, anemia

**SKIN:** Allergic dermatitis, ecchymosis, petechiae

**Other:** **Anaphylaxis**, **angioedema**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Crush chlorzoxazone tablets and mix with food or liquid for easier swallowing, if needed.
- Assess patients, especially those who have a history of allergies, for evidence of hypersensitivity, such as hives, itching, and rash.

**WARNING** Monitor patient for signs of hepatotoxicity, including darkened urine, fever, jaundice, and rash. Notify prescriber immediately and expect to

discontinue drug if any of these signs or symptoms occur. Monitor patient for abnormal liver function test results, such as elevated ALT, AST, alkaline phosphatase, and bilirubin levels, and expect to discontinue drug, as ordered, if any of these occurs.

- Ensure adequate rest, and provide other pain-relief measures as needed.
- Institute safety measures to prevent falls or injury until drug's full CNS effects are known.

## **PATIENT TEACHING**

- Advise patient to take a missed dose of chlorzoxazone as soon as possible unless it's almost time for the next dose.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to avoid alcohol and other CNS depressants during therapy.
- Inform patient that, in rare instances, urine may turn orange or reddish purple during therapy.
- Advise patient to store drug in a tightly capped container at room temperature.

## **cholestyramine**

**Locholest, Locholest Light,  
Prevalite, Questran, Questran Light**

## **Class and Category**

*Pharmacologic class:* Bile acid sequestrant

*Therapeutic class:* Antihyperlipidemic, antipruritic (cholestasis)

## Indications and Dosages

- *As adjunct to reduce serum cholesterol level in patients with primary hyper-cholesterolemia, to reduce LDL cholesterol in patients who also have hypertriglyceridemia when hypertriglyceridemia is not the abnormality of most concern, to relieve pruritus associated with partial biliary obstruction*

## ORAL SUSPENSION

**Adults.** *Initial:* 4 g once or twice daily before meals increased every 4 wks or more, as needed. *Maintenance:* 8 to 16 g equally divided and given 1 to 6 times a day. *Maximum:* 24 g daily.

Route	Onset	Peak	Duration
P.O.	In 1-2 wk*	Unknown	2-4 wk <sup>†</sup>

\* For hypercholesterolemia; in 1 to 3 wk for pruritus.

† For hypercholesterolemia; 1 to 2 wk for pruritus.

## Mechanism of Action

Increases bile acid excretion in feces. The resulting decreased bile acid level increases the activity of the enzyme that regulates cholesterol synthesis in the liver. As a result, the liver increases its cholesterol synthesis to produce more bile acids. However, the liver's synthesis of cholesterol typically can't match the amount needed to synthesize bile acids, which reduces the cholesterol level. Also, a decreased cholesterol level causes liver cells to

increase their uptake of LDLs, which further reduces the cholesterol level. Cholestyramine may relieve pruritus by decreasing the body's bile acid level. This reduces the amount of excess bile acids that are deposited in the dermis and that typically cause pruritus in patients with cholestasis.

## **Contraindications**

Complete biliary obstruction (when bile isn't secreted into intestine), hypersensitivity to cholestyramine or its components

## **Interactions**

### **DRUGS**

*oral drugs such as chenodiol, digitalis glycosides, estrogens, fat-soluble vitamins, folic acid, gemfibrozil, penicillin G (oral), phenobarbital (oral), phenylbutazone, progestins, propranolol (oral), tetracyclines (oral), thiazide diuretics (oral), thyroid hormones, ursodiol, vancomycin (oral), warfarin:* Decreased absorption and effects of these drugs

## **Adverse Reactions**

**CNS:** Dizziness, headache

**GI:** Bloating, constipation, diarrhea, epigastric pain, eructation, fecal impaction, flatulence, indigestion, nausea, vomiting

## **Childbearing Considerations**

## PREGNANCY

- It is not known if drug causes fetal harm.
- Be aware that drug interferes with absorption of fat-soluble vitamins, which may make regular prenatal supplementation inadequate.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- Be aware that the possibility of a lack of proper vitamin absorption may affect the breastfed infant.

## Nursing Considerations

- Store cholestyramine at room temperature.
- Don't give dry powder because it may cause esophageal distress; mix it in a beverage.

**WARNING** Be aware that long-term use may increase bleeding tendency from hyperprothrombinemia caused by vitamin K deficiency. If this occurs, patient will require treatment with vitamin K<sub>1</sub>.

- Monitor for deficiencies of fat-soluble vitamins, such as A and D. If long-term therapy prevents absorption of these vitamins, expect to provide supplementation.

## PATIENT TEACHING

- Urge patient to follow a low-cholesterol, low-fat diet and regular exercise program.

- Tell patient to take drug before meals.
- Instruct patient to mix dry powder as follows: Place amount of powder needed for dose in any beverage and stir vigorously. Then, vigorously stir in another 2 to 4 ounces of beverage. After drinking mixture, rinse glass with more liquid, and swallow it to make sure full dose is taken. Patient also may mix drug in thin soups or moist, pulpy fruits, such as applesauce or crushed pineapple.
- Tell patient to drink plenty of fluids and increase bulk in his diet to minimize constipation; remind him to notify prescriber if constipation, nausea, or other adverse GI reactions develop.
- Explain that serum cholesterol level will need to be measured often for first few months of therapy and periodically thereafter.
- Advise patient to take other drugs at least 1 hour before or 4 to 6 hours after cholestyramine to avoid interference with their absorption.
- Tell patient to take a missed dose as soon as he remembers but not to take double or extra doses.

## ciclesonide

**Alvesco, Omnaris, Zetonna**

### Class and Category

*Pharmacologic class:* Corticosteroid

*Therapeutic class:* Antiasthmatic, anti-inflammatory

### Indications and Dosages

- *To provide maintenance therapy for patients with asthma*

### INHALATION AEROSOL (ALVESCO)

**Adults and children age 12 and over who received bronchodilator therapy.** *Initial:* 80 mcg twice daily.

*Maximum:* 160 mcg twice daily.

**Adults and children age 12 and over who received inhaled corticosteroid.** *Initial:* 80 mcg twice daily, adjusted to lowest effective dose when stabilized.

*Maximum:* 320 mg twice daily.

**Adults and children age 12 and over who received oral corticosteroid therapy.** *Initial and maximum:* 320 mcg twice daily, adjusted to lowest effective dose when stabilized.

➤ *To treat nasal congestion in seasonal allergic rhinitis*

## **NASAL SPRAY (OMNARIS)**

**Adults and children age 6 and over.** 200 mcg once daily as 2 sprays in each nostril.

## **NASAL AEROSOL (ZETONNA)**

**Adults and children age 12 and over.** 74 mcg once daily as 1 spray in each nostril.

➤ *To treat nasal congestion in perennial allergic rhinitis*

## **NASAL SPRAY (OMNARIS)**

**Adults and children age 12 and over.** 200 mcg once daily as 2 sprays in each nostril.

## **NASAL AEROSOL (ZETONNA)**

**Adults and children age 12 and over.** 74 mcg once daily as 1 spray (37 mcg) in each nostril.

---

Route	Onset	Peak	Duration
Inhalation	Unknown	4 wk or longer	Several days

Route	Onset	Peak	Duration
Nasal aerosol	Unknown	Unknown	Unknown

## Mechanism of Action

Inhibits cells involved in the asthma inflammatory response, such as basophils, eosinophils, lymphocytes, macrophages, mast cells, and neutrophils. Ciclesonide also inhibits production or secretion of chemical mediators, such as cytokines, eicosanoids, histamine, and leukotrienes.

## Contraindications

Hypersensitivity to ciclesonide or its components, primary treatment of status asthmaticus or other acute asthma episodes that require intensive measures (Alvesco)

## Interactions

### DRUGS

*ketoconazole*: Increased exposure time of ciclesonide

## Adverse Reactions

**CNS:** Dizziness, fatigue, headache

**EENT:** Cataracts, conjunctivitis, dry mouth or throat, dysphonia, epistaxis, glaucoma, hoarseness, nasal congestion or ulceration, nasal septal perforation, nasopharyngitis, oral candidiasis, pharyngolaryngeal pain, sinusitis

**ENDO:** **Adrenal insufficiency**, cushingoid symptoms, decreased bone mineral density, hyperglycemia, slower growth in children

**GI:** Nausea

**MS:** Arthralgia, back or limb pain, musculoskeletal chest pain

**RESP:** **Bronchospasm**, cough, pneumonia, upper respiratory tract infection

**SKIN:** Urticaria

**Other:** **Angioedema**, flu-like symptoms, infections

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm although hypoadrenalism may occur in neonates born of mothers receiving corticosteroids during pregnancy.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that ciclesonide should not be used in patients with recent nasal septal ulcers, nasal surgery, or nasal trauma until healing has occurred.
- Use cautiously in patients with tuberculosis; bacterial, fungal, parasitic, or viral infection; ocular herpes simplex; or chickenpox or measles because these conditions may worsen with ciclesonide therapy.
- Also use cautiously in patients with a history of cataracts, glaucoma, or increased intraocular pressure because ciclesonide may increase intraocular pressure or cause cataract formation; and in patients with

major risk factors for decreased bone mineral content, such as family history of osteoporosis, prolonged immobilization, or long-term use of drugs that can reduce bone mass, such as anticonvulsants and oral corticosteroids.

- Inspect patient's oral cavity if using inhaler form, or nasal cavity if using nasal spray regularly for abnormalities. Have patient rinse mouth following inhalation of ciclesonide to reduce risk of oral candidiasis. If nasal or oral candidiasis occurs, expect to continue ciclesonide therapy, unless severe. If nasal erosion, ulceration, or perforation occurs, notify prescriber and expect nasal spray to be discontinued.
- Be aware that if patient takes a systemic corticosteroid, expect to taper dosage by no more than 2.5 mg/day at weekly intervals, starting 1 week after ciclesonide therapy begins.

**WARNING** Know that if patient is switched from systemic corticosteroid to ciclesonide, assess for adrenal insufficiency (fatigue, hypotension, lassitude, nausea, vomiting, weakness) early in therapy and whenever patient has infection, stress, surgery, or trauma, or other steroid-depleting conditions or procedures. Notify prescriber immediately if signs or symptoms develop.

- Administer a fast-acting inhaled bronchodilator, as prescribed, if an acute asthma attack occurs. Ciclesonide inhalation is not a bronchodilator and its action takes longer than needed to abort acute asthma symptoms. If bronchospasm occurs immediately after ciclesonide use, expect to stop drug and start another drug regimen.
- Monitor growth in children because ciclesonide may suppress growth.

## **PATIENT TEACHING**

- Urge patient to use ciclesonide regularly, as prescribed, but not for acute bronchospasm. Also tell her never to increase or decrease the dosage without consulting prescriber.
- Tell patient to use inhalation form only with the actuator supplied with the product. Explain that when the dose indicator shows a red zone in the window, about 20 inhalations are left, indicating a need for a refill. When the indicator shows zero, she should discard the inhaler. Advise against relying solely on the dose indicator, especially if inhaler has been dropped, but to keep track of number of inhalations used.

- Instruct patient to use inhaler form according to package instructions. Emphasize need to make sure canister is firmly seated in the plastic mouthpiece adapter before each use and to press inhaler slowly but firmly until it can go no further in the adapter for each spray. Inform patient that she doesn't need to shake inhaler before use.
- Advise her on first use, to spray three times into the air (away from her eyes), looking for a fine mist. If inhaler or spray hasn't been used for more than 4 days (Omnaris) or 10 days (Alvesco, Zetonna), it should be primed again.
- Advise patient using nasal spray form to avoid spraying the drug directly onto the nasal septum.
- Instruct patient to gargle and rinse her mouth after each dose of inhaler to help prevent dry mouth and throat, relieve throat irritation, and prevent oral yeast infection.
- Tell patient to always replace cap on inhaler after use, to keep mouthpiece clean, and to clean mouthpiece once a week with a clean, dry tissue or cloth.
- Explain that the full effect of drug may not occur for 4 weeks or more.
- Stress importance of notifying prescriber if symptoms continue or worsen.
- Instruct patient to notify prescriber immediately if asthma attacks don't respond to bronchodilators during ciclesonide inhaler use.
- Make patient aware that if she is switching from an oral corticosteroid to inhaled ciclesonide, she should carry medical identification indicating the need for supplemental systemic corticosteroids during a severe asthma attack or stress.
- Caution patient to avoid contact with people who have infections because drug suppresses the immune system, increasing the risk of infection. Instruct patient to notify prescriber about exposure to chickenpox, measles, or other infections because additional treatment may be needed.

# cilostazol

## Pletal

# Class and Category

*Pharmacologic class: Phosphodiesterase 3 (PDE 3) inhibitor*  
*Therapeutic class: Antiplatelet*

## Indications and Dosages

➤ *To reduce symptoms of intermittent claudication*

### **TABLETS**

**Adults.** 100 mg twice daily taken at least 30 min before or 2 hr after breakfast and dinner.

***DOSAGE ADJUSTMENT*** For patient taking a moderate or strong CYP3A4 inhibitor (diltiazem, erythromycin, itraconazole, ketoconazole) or taking a CYP2C19 inhibitor (fluconazole, omeprazole, ticlopidine), dosage reduced to 50 mg twice daily.

## Mechanism of Action

May inhibit phosphodiesterase, decreasing phosphodiesterase activity and suppressing cyclic adenosine monophosphate (cAMP) degradation. This action increases cAMP in platelets and blood vessels, which inhibits platelet aggregation and causes vasodilation. This in turn relieves symptoms of claudication.

## Contraindications

Heart failure, hypersensitivity to cilostazol or its components

## Interactions

## DRUGS

*CYP2C19 inhibitors (e.g., fluconazole, omeprazole, ticlopidine) or CYP3A4 inhibitors (e.g., diltiazem, erythromycin, omeprazole, ticlopidine):* Increased plasma cilostazol level

## FOODS

*grapefruit:* Increased risk of adverse reactions

*high-fat foods:* Faster cilostazol absorption and increased risk of adverse reactions

## ACTIVITIES

*smoking:* Decreased cilostazol effects by about 20%

## Adverse Reactions

**CNS:** Cerebral hemorrhage, dizziness, headache, paresthesia

**CV:** Angina, chest pain, hypertension, hypotension, left ventricular outflow tract obstruction (patients with sigmoid-shaped interventricular septum), palpitations, peripheral edema, prolonged QT interval, supraventricular or ventricular tachycardia, thrombosis, torsades de pointes

**EENT:** Pharyngitis, rhinitis

**ENDO:** Diabetes mellitus, hot flashes, hyperglycemia

**GI:** Abdominal pain, abnormal stool, diarrhea, elevated liver enzymes, flatulence, GI hemorrhage, hepatic dysfunction, indigestion, jaundice, vomiting

**GU:** Elevated BUN level, hematuria

**HEME:** Agranulocytosis, aplastic anemia, bleeding tendency, decreased platelet count, granulocytopenia, leukopenia, pancytopenia, thrombocytopenia

**MS:** Back pain, myalgia

**RESP:** Cough, interstitial pneumonia, pulmonary hemorrhage

**SKIN:** Eruptions, pruritus, rash, Stevens-Johnson syndrome

**Other:** Infection, increased blood uric acid level

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Monitor patient's vital signs and cardiovascular status closely because cilostazol may cause cardiovascular lesions, which could lead to problems, such as endocardial hemorrhage.
- Be aware that left ventricular outflow tract obstruction has been reported in patients with sigmoid-shaped interventricular septum. Monitor patients for development of new cardiac symptoms, including a systolic murmur, after starting cilostazol.

- Monitor blood glucose level to detect hyperglycemia. Also assess for signs of type 2 diabetes mellitus, such as fatigue, polydipsia, polyphagia, and polyuria.

## PATIENT TEACHING

- Instruct patient to take cimetazol on an empty stomach because high-fat foods can increase the risk of adverse reactions.
- Warn patient to avoid grapefruit juice during therapy because it can increase the risk of adverse reactions.
- Urge patient not to smoke because it decreases drug's effects.
- Explain that assessment of drug effectiveness is based on ability to walk increased distances. Stress that drug effects won't appear until 2 to 4 weeks after therapy starts and that full effects may take up to 12 weeks.

**cimetidine**

**Tagamet, Tagamet HB**

**cimetidine hydrochloride**

## Class and Category

*Pharmacologic class:* Histamine H<sub>2</sub> antagonist

*Therapeutic class:* Antiulcer agent

## Indications and Dosages

➤ *To treat and prevent recurrence of duodenal ulcer*

**ORAL SOLUTION, TABLETS**

**Adults and adolescents age 16 and over.** *Initial:* 800 mg (or 1,600 mg if ulcer is greater than 1.0 cm and patient is heavy smoker) at bedtime. Alternatively, 300 mg four times daily with meals and at bedtime, or 400 to 600 mg in morning and at bedtime for 4 to 6 wk. *Maintenance:* 400 mg at bedtime.

## **I.V. OR I.M. INJECTION**

**Adults.** *Initial:* 300 mg every 6 to 8 hr. I.V. given slowly over 5 min.

## **I.V. INFUSION**

**Adults.** 37.5 mg/hr if continuous or infused over 15 to 20 min if given intermittently. *Maximum:* 100 mg/hr (2,400 mg daily).

➤ *To treat active, benign gastric ulcer*

## **ORAL SOLUTION, TABLETS**

**Adults and adolescents age 16 and over.** 800 mg at bedtime or 300 mg four times daily with meals and at bedtime for up to 8 wk.

## **I.V. OR I.M. INJECTION**

**Adults and adolescents age 16 and over.** 300 mg every 6 to 8 hr. I.V. given slowly over at least 5 min.

## **I.V. INFUSION**

**Adults and adolescents age 16 and over.** *Initial:* 37.5 mg/hr if given continuously or infused over 15 to 20 min if given intermittently, increased as needed. *Maximum:* 2,400 mg daily.

➤ *To manage erosive gastroesophageal reflux disease*

## ORAL SOLUTION, TABLETS

**Adults.** 1,600 mg daily in divided doses (800 mg twice daily or 400 mg four times daily) for up to 12 wk.

- *To treat pathological hypersecretory conditions, such as Zollinger-Ellison syndrome*

## ORAL SOLUTION, TABLETS

**Adults and adolescents age 16 and over.** 300 mg four times daily with meals and at bedtime, increased in dosage and/or frequency, if needed. *Maximum:* 2,400 mg daily.

## I.V. OR I.M. INJECTION

**Adults and adolescents age 16 and over.** 300 mg every 6 to 8 hr. I.V. given slowly over at least 5 min.

## I.V. INFUSION

**Adults.** *Initial:* 37.5 mg/hr if given continuously or infused over 15 to 20 min if given intermittently, increased as needed. *Maximum:* 2,400 mg daily.

- *To treat heartburn and acid indigestion*

## ORAL SOLUTION, TABLETS

**Adults and children age 12 and over.** *Initial:* 200 mg with water at onset of symptoms or up to 30 minutes before eating. *Maximum:* 400 mg every 24 hr for no more than 2 wk unless prescribed.

- *To prevent stress-related upper GI bleeding during hospitalization*

## I.V. INFUSION

**Adults.** 50 mg/hr by continuous infusion for 7 days.

**DOSAGE ADJUSTMENT** For patient with severe renal impairment, dosage reduced to 300 mg and frequency lengthened to every 12 hr (and increased to every 8 hr with caution, if needed). For patient with a creatinine clearance less than 30 ml/min and being treated to prevent stress-related upper GI bleeding during hospitalization, dosage reduced by 50%.

Route	Onset	Peak	Duration
P.O.	Unknown	1-2 hr	4-5 hr
I.V., I.M.	Unknown	Unknown	4-5 hr

## Mechanism of Action

Blocks histamine's action at H<sub>2</sub>-receptor sites on stomach's parietal cells. This action reduces gastric fluid volume and acidity. Cimetidine also decreases the amount of gastric acid secreted in response to betazole, caffeine, food, insulin, or pentagastrin.

## Incompatibilities

Don't mix cimetidine with aminophylline or barbiturates in I.V. solution. Don't mix drug with pentobarbital sodium in the same syringe.

## Contraindications

Hypersensitivity to cimetidine or its components

## Interactions

### DRUGS

*antacids, metoclopramide*: Decreased cimetidine absorption

*chlordiazepoxide, diazepam, lidocaine, metronidazole, nifedipine, phenytoin, propranolol, quinidine, theophylline, tricyclic antidepressants (certain ones), warfarin*: Reduced metabolism and increased blood levels and effects of these drugs, possibly toxicity from these drugs

*digoxin, ketoconazole*: Altered absorption of these drugs  
*warfarin*: Increased risk of bleeding

## **FOODS**

*caffeine*: Reduced metabolism and increased blood level and effects of caffeine

## **ACTIVITIES**

*alcohol use*: Possibly increased blood alcohol level

## **Adverse Reactions**

**CNS**: Confusion, dizziness, hallucinations, headache, peripheral neuropathy, somnolence

**ENDO**: Mild gynecomastia if used longer than 1 month

**GI**: Mild and transient diarrhea

**GU**: Impotence, transiently elevated serum creatinine level

**SKIN**: Rash

**Other**: Pain at I.M. injection site

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## Nursing Considerations

**WARNING** Be aware that rapid administration of cimetidine can increase risk of arrhythmias and hypotension.

- For I.V. injection, dilute cimetidine in normal saline solution to a total volume of 20 ml. Inject over 5 minutes or more.
- For intermittent I.V. infusion, dilute cimetidine in at least 50 ml of D<sub>5</sub>W or other compatible I.V. solution. Infuse over 15 to 20 minutes.
- For I.M. injection, don't dilute cimetidine before administering it.
- Be alert for confusion in debilitated or elderly patients who receive cimetidine.

## PATIENT TEACHING

- Tell patient to use a liquid-measuring device to ensure accurate dose of solution.
- Advise patient to avoid alcohol while taking cimetidine to prevent interactions.
- Instruct patient to avoid taking antacids within 1 hour of taking cimetidine.
- Warn patient that cigarette smoking increases gastric acid secretion and can worsen gastric disease.
- Caution patient not to take drug for more than 14 days, unless prescribed.

# cinacalcet hydrochloride

**Sensipar**

## Class and Category

*Pharmacologic class:* Calcimimetic

*Therapeutic class:* Calcium reducer

## Indications and Dosages

- *To treat secondary hyperparathyroidism in patients with chronic renal disease who are on dialysis*

### **TABLETS**

**Adults.** *Initial:* 30 mg daily, increased by 30 mg every 2 to 4 wk daily, as needed. *Maximum:* 180 mg daily.

- *To treat hypercalcemia in patients with parathyroid carcinoma; to treat primary hyperparathyroidism in patients who are unable to undergo parathyroidectomy*

### **TABLETS**

**Adults.** *Initial:* 30 mg twice daily, increased in 2 to 4 wk to 60 mg twice daily, then in 2 to 4 wk to 90 mg twice daily, and then in 2 to 4 wk to 90 mg three times daily or four times daily, as needed to normalize serum calcium level.

Route	Onset	Peak	Duration
P.O.	Unknown	2-6 hr	Unknown

## Mechanism of Action

Increases sensitivity of calcium-sensing receptors on the surface of parathyroid cells to extracellular calcium. This sensitivity directly reduces parathyroid hormone (PTH) level, which in turn decreases serum calcium level.

## Contraindications

Hypersensitivity to cinacalcet or its components, hypocalcemia

## Interactions

### DRUGS

*CYP2D6 substrates, such as carvedilol, desipramine, metoprolol; drugs that have a narrow therapeutic index, such as flecainide, tricyclic antidepressants (most):* Possibly increased blood level of these drugs  
*other calcium lowering drugs including other calcium-sensing receptor agonists:* Increased risk of severe hypocalcemia  
*strong CYP3A4 inhibitors such as itraconazole, ketoconazole:* Possibly increased blood cinacalcet level

## Adverse Reactions

**CNS:** Asthenia, dizziness, **seizures**

**CV:** **Arrhythmias**, hypertension, **hypotension** (in the presence of impaired cardiac function), **worsening heart failure** (in the presence of impaired cardiac function)

**GI:** Anorexia, diarrhea, **gastrointestinal bleeding**, nausea, vomiting

**MS:** Adynamic bone disease, myalgia

**SKIN:** Rash, urticaria

**Other:** Acute pseudogout, allergic reaction, **angioedema**, **hypocalcemia**, noncardiac chest pain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that cinacalcet is not recommended for use in patients with chronic kidney disease who are not on dialysis because of an increased risk of hypocalcemia.
- Use cinacalcet cautiously in patients with a history of seizures because reduced blood calcium level may lower seizure threshold. Also use cautiously in patients with hepatic insufficiency because cinacalcet metabolism may be reduced.

**WARNING** Monitor patient for hypocalcemia exhibited by cramping, myalgia, paresthesia, prolonged QT interval that may cause ventricular arrhythmias, seizures, and tetany. Also monitor patient's blood calcium and phosphorus levels within 1 week after starting therapy or adjusting dosage, and every month or two once

maintenance dose is established, as ordered. If hypocalcemia develops, notify prescriber immediately because treatment to raise calcium level will be needed. Treatment may include giving supplemental calcium, starting or increasing dosage of calcium-based phosphate binder or vitamin D sterols, or temporarily withholding cinacalcet.

- Be aware that if patient starts or stops therapy with a strong CYP3A4 inhibitor, such as itraconazole, or ketoconazole, cinacalcet dosage may have to be adjusted.
- Monitor dialysis patient's intact PTH levels 1 to 4 weeks after therapy starts or dose is adjusted and then every 1 to 3 months thereafter, as ordered. Keep in mind that adynamic bone disease may develop if iPTH levels drop below 100 pg/ml. Expect to reduce dosage or discontinue cinacalcet, as ordered, in a patient whose intact PTH level falls below the target range of 150 to 300 pg/ml.
- Monitor patient for worsening of common gastrointestinal adverse reactions of nausea and vomiting associated with cinacalcet therapy and for signs and symptoms of GI bleeding and ulcerations. Risk factors include esophagitis, gastritis, severe vomiting, or ulcers. Notify prescriber if such symptoms present, and provide supportive care, as ordered.

## **PATIENT TEACHING**

- Instruct patient to take cinacalcet with food or shortly after a meal.
  - Caution patient to take tablet whole and not divide it or crush it.
  - Review signs and symptoms of hypocalcemia with patient and urge him to notify prescriber of changes.
  - Advise patient to report any symptoms of gastrointestinal bleeding, nausea, or vomiting to prescriber.
  - Alert patient with heart failure that cinacalcet may worsen the heart failure requiring additional monitoring of their condition.
  - Inform patient that regular blood tests will be ordered to monitor the safe use of cinacalcet and the importance of actually having the tests done.
-

# ciprofloxacin

**Cipro, Cipro I.V., Cipro XR, Otiprio**

## Class and Category

*Pharmacologic class:* Fluoroquinolone derivative

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To prevent inhalation anthrax after exposure*

### ORAL SUSPENSION, TABLETS

**Adults.** 500 mg every 12 hr for 60 days.

**Children.** 15 mg/kg every 12 hr for 60 days. *Maximum:* 500 mg/dose.

### I.V. INFUSION

**Adults.** 400 mg infused over 60 min every 12 hr for 60 days.

**Children.** 10 mg/kg every 12 hr for 60 days. *Maximum:* 400 mg per dose.

- *To treat acute sinusitis caused by susceptible organisms*

### ORAL SUSPENSION, TABLETS

**Adults.** 500 mg every 12 hr for 10 days.

### I.V. INFUSION

**Adults.** 400 mg infused over 60 min every 12 hr for 10 days.

- *To treat bone and joint infections caused by susceptible organisms*

## **ORAL SUSPENSION, TABLETS**

**Adults.** For mild to moderate infections, 500 mg every 12 hr for 4 to 8 wk. For severe or complicated infections, 750 mg every 12 hr for 4 to 8 wk.

## **I.V. INFUSION**

**Adults.** For mild to moderate infections, 400 mg infused over 60 min every 12 hr for 4 to 8 wk. For severe or complicated infections, 400 mg infused over 60 min every 8 hr for 4 to 8 wk.

- *To treat skin and soft-tissue infections caused by susceptible organisms*

## **ORAL SUSPENSION, TABLETS**

**Adults.** For mild to moderate infections, 500 mg every 12 hr for 7 to 14 days. For severe or complicated infections, 750 mg every 12 hr for 7 to 14 days.

## **I.V. INFUSION**

**Adults.** For mild to moderate infections, 400 mg infused over 60 min every 12 hr for 7 to 14 days. For severe or complicated infections, 400 mg infused over 60 min every 8 hr for 7 to 14 days.

- *To treat chronic bacterial prostatitis caused by susceptible organisms*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 500 mg every 12 hr for 28 days.

## **I.V. INFUSION**

**Adults.** 400 mg infused over 60 min every 12 hr for 28 days.

- *To treat infectious diarrhea caused by susceptible organisms*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 500 mg every 12 hr for 5 to 7 days.

- *To treat UTI caused by susceptible organisms*

## **ORAL SUSPENSION, TABLETS**

**Adults.** For mild to moderate infections, 250 mg every 12 hr for 7 to 14 days. For severe or complicated infections, 500 mg every 12 hr for 7 to 14 days.

## **I.V. INFUSION**

**Adults.** For mild to moderate infections, 200 mg infused over 60 min every 12 hr for 7 to 14 days. For severe or complicated infections, 400 mg infused over 60 min every 8 hr for 7 to 14 days.

- *To treat plague, including pneumonic and septicemic plague, due to Yersinia pestis*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 500 to 750 mg every 12 hr for 14 days.

**Children.** 15 mg/kg every 8 to 12 hr for 10 to 21 days.  
*Maximum:* 500 mg/dose.

## **I.V. INFUSION**

**Adults.** 400 mg infused over 60 min every 8 to 12 hr for 14 days.

**Children.** 10 mg/kg infused over 60 min every 8 to 12 hr for 10 to 21 days. *Maximum:* 400 mg/dose

- *To prevent plague postexposure*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 500 mg every 12 hr for 14 days.

**Children.** 15 mg/kg every 8 to 12 hr for 14 days.

*Maximum:* 1 g daily.

- *To treat acute uncomplicated urinary tract infection oral suspension, tablets*

**Adults.** 250 mg every 12 hr for 3 days.

## **E.R. TABLETS**

**Adults.** 500 mg daily for 3 days.

- *To treat acute uncomplicated pyelonephritis; to treat complicated urinary tract infection*

## **E.R. TABLETS**

**Adults.** 1,000 mg daily for 7 to 14 days.

- *To treat lower respiratory tract infections caused by susceptible organisms*

## **ORAL SUSPENSION, TABLETS**

**Adults.** For mild to moderate infections, 500 mg every 12 hr for 7 to 14 days. For severe or complicated infections, 750 mg every 12 hr for 7 to 14 days. i.v. infusion

**Adults.** For mild to moderate infections, 400 mg infused over 60 min every 12 hr for 7 to 14 days. For severe or complicated infections, 400 mg infused over 60 min every 8 hr for 7 to 14 days.

- *To treat complicated intra-abdominal infections caused by susceptible organisms*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 500 mg every 12 hr for 7 to 14 days.

## **I.V. INFUSION**

**Adults.** 400 mg infused over 60 min every 12 hr for 7 to 14 days.

- *To treat nosocomial pneumonia caused by susceptible organisms*

## **I.V. INFUSION**

**Adults.** 400 mg infused over 60 min every 8 hr for 10 to 14 days.

- *To treat typhoid fever caused by susceptible organisms*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 500 mg every 12 hr for 10 days.

- *To treat uncomplicated urethral or cervical gonococcal infections caused by N. gonorrhoeae*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 250 mg as a single dose.

- *To provide empirical therapy in febrile neutropenic patients*

## **I.V. INFUSION**

**Adults.** 400 mg infused over 60 min every 8 hr for 7 to 14 days given concomitantly with piperacillin.

- *To treat acute otitis externa caused by Pseudomonas aeruginosa or Staphylococcus aureus*

## **OTIC SUSPENSION (OTIPRIO)**

**Children age 6 months and over.** 0.2 ml (12 mg) as a single dose to the external ear canal of each affected ear.

***DOSAGE ADJUSTMENT*** For patients taking oral suspension or tablets, dosage reduced to 250 to 500 mg every 12 hour if creatinine clearance is 30 to 50 ml/min; and to 250 to 500 mg every 18 hr if creatinine clearance is 5 to 29 ml/min. For patient on dialysis, dosage reduced to 250 mg to 500 mg every 24 hr and given after dialysis. For patient with a creatinine clearance of 30 ml/min or less taking E.R. tablets, dosage reduced to 500 mg daily and drug administered after dialysis, if patient is receiving dialysis. For patient receiving drug intravenously and who has a creatinine clearance between 5 to 29 ml/min, dosage reduced to 200 to 400 mg every 18 to 24 hr.

## **Mechanism of Action**

Inhibits the enzyme DNA gyrase, which is responsible for the unwinding and supercoiling of bacterial DNA before it replicates. By inhibiting this enzyme, ciprofloxacin causes bacterial cells to die.

## **Incompatibilities**

Don't administer parenteral ciprofloxacin with aminophylline, amoxicillin, cefepime, clindamycin, dexamethasone, floxacillin, furosemide, heparin, or phenytoin.

## **Contraindications**

Concurrent therapy with tizanidine; hypersensitivity to ciprofloxacin, *other quinolones, or their components*

## Interactions

### DRUGS

*antacids, didanosine, iron supplements, multivitamins that contain iron or zinc sucralfate*: Decreased ciprofloxacin absorption

*caffeine, clozapine, duloxetine, methotrexate, methylxanthines, olanzapine, ropinirole, sildenafil, zolpidem*: Increased plasma levels of these drugs and increased risk of serious adverse reactions including toxicity

*cyclosporine*: Elevated serum creatinine

*drugs that prolong QT interval such as class IA or III*

*antiarrhythmics, antipsychotics, macrolides, tricyclic*

*antidepressants*: Increased risk of further QT prolongation

*NSAIDs (except acetylsalicylic acid)*: Increased risk of seizures with high doses of ciprofloxacin

*oral anticoagulants*: Enhanced anticoagulant effects

*oral hypoglycemics*: Possibly increased risk of hypoglycemia that may be severe (especially with glyburide)

*phenytoin*: Increased or decreased blood phenytoin level

*probenecid*: Increased blood ciprofloxacin level and, possibly, toxicity

*theophylline*: Increased risk of CNS or other serious adverse reactions

*tizanidine*: Potentiation of hypotensive and sedative effects of tizanidine

### FOODS

*caffeine*: Increased caffeine effects

*dairy products*: Delayed drug absorption

## Adverse Reactions

**CNS**: Abnormal gait, agitation, anxiety, ataxia, **cerebral thrombosis**, confusion delirium, depersonalization, depression, disorientation, disturbance in attention, dizziness, drowsiness, fever, hallucinations, headache, **increased intracranial pressure including pseudotumor cerebri**, insomnia, irritability, lethargy, light-headedness, malaise, manic reaction, memory impairment, migraine, nervousness, nightmares, paranoia, paresthesia, peripheral neuropathy, phobia, restlessness, **seizures, status epilepticus, suicidal ideation**, syncope, tremor, toxic psychosis, unresponsiveness, weakness

**CV**: Angina, **aortic aneurysm and dissection, atrial flutter, cardiopulmonary arrest, cardiovascular collapse**, hypertension, **MI**, orthostatic hypotension, palpitations, phlebitis, tachycardia, **torsades de pointes**, vasculitis, **ventricular ectopy**

**EENT**: Oral candidiasis

**ENDO**: Hyperglycemia, **hypoglycemia**

**GI**: Abdominal pain, anorexia, constipation, diarrhea, dysphagia, elevated liver enzymes, flatulence, **GI bleeding, hepatic failure or necrosis, hepatitis**, indigestion, **intestinal perforation**, jaundice, nausea, **pancreatitis, pseudomembranous colitis**, vomiting

**GU**: **Acute renal failure or insufficiency**, crystalluria, hematuria, increased serum creatinine level, interstitial nephritis, **nephrotoxicity**, renal calculi, urine retention, vaginal candidiasis

**HEME:** Agranulocytosis, aplastic or hemolytic anemia, bone marrow depression, leukopenia, lymphadenopathy, pancytopenia, thrombocytopenia

**MS:** Arthralgia, myalgia, tendinitis, tendon rupture

**RESP:** Allergic pneumonitis, bronchospasm, pulmonary embolism, respiratory arrest

**SKIN:** Acute generalized exanthematous pustulosis (AGEP), erythema multiforme, exfoliative dermatitis, photosensitivity, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

**Other:** Acidosis, anaphylaxis, angioedema, serum sickness-like reaction

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding temporarily during drug therapy or discontinue the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Obtain culture and sensitivity test results, as ordered, before giving ciprofloxacin.

- Know that ciprofloxacin should not be used in a patient with myasthenia gravis as it may exacerbate muscle weakness.
- Know that ciprofloxacin should not be given to patients with a known aortic aneurysm or patients who are at greater risk for aortic aneurysms, unless no alternative antibacterial treatment is available. This is because studies suggest an increased risk of aortic aneurysm and dissection within two months following use of fluoroquinolones, especially in the elderly.
- Use drug cautiously in patients with CNS disorders and disorders that may predispose patient to seizures, such as history of epilepsy or conditions that may lower the seizure threshold, such as history of altered brain structure, reduced cerebral blood flow, severe cerebral arteriosclerosis, or stroke. Take seizure precautions. If a seizure occurs, expect ciprofloxacin to be discontinued immediately.
- Use drug cautiously in patients who may be more susceptible to drug's effect on QT interval, such as those taking Class IA or III antiarrhythmics; those with uncorrected hypokalemia or hypomagnesemia; or in the presence of a history of cardiac disease such as heart failure, QT-interval prolongation, or torsades de pointes.
- Know that E.R. and immediate-release tablets aren't interchangeable.
- Be aware that during preparation of otic suspension (Otiprio) for each ear, the product must be kept cold. If solution thickens during preparation, the vial should be placed back in refrigeration. Shake vial for 5 to 8 seconds to mix well until a visually homogenous suspension is obtained. Hold vial by the aluminum seal to prevent gelation when shaking vial. Using an 18- to 21-gauge needle, withdraw 0.3 ml of the suspension into the 1-ml syringe. Replace the needle with a 20- to 24-gauge, 1.5-inch blunt, flexible catheter. Prime the syringe after the administration catheter has been attached by leaving a dose of 0.2 ml in the syringe. Know that the syringes can be kept at room temperature or in the refrigerator prior to administration, but the syringes must be kept on their sides. Discard syringes if not administered in 3 hours.
- Be aware that patient should be well hydrated during therapy to help prevent alkaline urine, which may lead to crystalluria and nephrotoxicity.
- Assess patient's hematologic, hepatic, and renal functions periodically, as ordered. Report any abnormalities, including signs and symptoms of dysfunction, to prescriber. For example, severe liver toxicity has occurred with ciprofloxacin use (within 1 to 39 days of therapy) and has been associated more frequently with hypersensitivity reactions. If dysfunction occurs, expect drug to be discontinued and provide supportive care, as ordered and needed.

- Assess patient routinely for signs of rash or other hypersensitivity reactions, even after patient has received multiple doses. Stop drug at first sign of rash, or other sign of hypersensitivity, and notify prescriber immediately. Be prepared to provide supportive emergency care.
- Monitor patient closely for diarrhea, which may reflect pseudomembranous colitis. If it occurs, notify prescriber and expect to withhold drug and treat diarrhea.
- Assess patient for evidence of peripheral neuropathy. Notify prescriber and expect to stop drug if patient complains of burning, numbness, pain, tingling, or weakness in extremities or if physical examination reveals deficits in light touch, motor strength, pain, position sense, temperature, or vibratory sensation.
- Monitor patients (especially children, elderly patients, patients receiving corticosteroids, and patients who have renal failure or who have had a heart, kidney, or lung transplant) for evidence of tendon rupture, such as inflammation, pain, and swelling at the site. Be aware that tendon rupture may occur within the first 48 hours of therapy, throughout therapy, or months after ciprofloxacin therapy. Notify prescriber about suspected tendon rupture, and have patient rest and refrain from exercise until tendon rupture has been ruled out. If present, expect to provide supportive care as ordered.
- Monitor patient closely for changes in behavior or mood that may be caused by ciprofloxacin-induced depression or worsening psychotic reactions potentially resulting in self-injurious behavior, such as suicide. Be aware these reactions may occur even after just one dose. Notify prescriber immediately and expect to discontinue ciprofloxacin therapy, if present, and institute precautions to keep patient safe until adverse effects have disappeared.
- Monitor patient's blood glucose levels, especially diabetic patients, and for signs and symptoms of changes in blood glucose levels. Both symptomatic hyperglycemia and hypoglycemia may occur as a result of ciprofloxacin therapy. If present, alert prescriber and initiate appropriate treatment, as prescribed. Also be aware that severe hypoglycemia has occurred when drug has been administered intravenously. If a hypoglycemic reaction occurs in a patient receiving drug intravenously, discontinue administration immediately and initiate appropriate emergency treatment for hypoglycemia.

## **PATIENT TEACHING**

- Urge patient to complete the prescribed course of therapy, even if he feels better before it's finished.

- Tell patient not to take drug with calcium-fortified juices or dairy products.
- Advise patient to take ciprofloxacin 2 hours before or 6 hours after antacids, iron supplements, or multivitamins that contain iron or zinc. Tell him to shake oral suspension for 15 seconds, not to chew microcapsules, and not to chew, crush, or split E.R. tablets. Advise patient to take drug about the same time every day and if prescribed a twice-daily dose to take first dose in the morning and second dose in the evening about 12 hours apart.
- Encourage patient to drink plenty of fluids during therapy to help prevent crystalluria.
- Urge patient to avoid caffeinated products because caffeine may accumulate in the body during ciprofloxacin therapy and cause excessive stimulation.

**WARNING** Instruct patient to seek emergency medical help immediately if sudden back, chest, or stomach pain occurs.

- Caution patient to avoid excessive exposure to sunlight or artificial ultraviolet light because severe sunburn may result. Tell patient to notify prescriber if sunburn develops; drug will need to be stopped.
- Urge patient to avoid hazardous activities until CNS effects of drug are known.
- Advise patient to notify prescriber about changes in limb movement or sensation and about inflammation, pain, or swelling over a joint. Urge patient to rest the affected limb at the first sign of discomfort.
- Tell patient to stop taking drug and to notify prescriber at first sign of rash or other hypersensitivity reaction.
- Urge patient to report bloody, watery stools to prescriber immediately, even up to 2 months after drug therapy has ended.
- Urge caregivers to monitor him closely for suicidal tendencies if patient develops depression or worsening of psychotic behavior and to notify prescriber.
- Warn patient, especially diabetic patient, that ciprofloxacin may alter blood glucose levels. Review signs and symptoms of hyperglycemia and hypoglycemia. Tell patient to report symptomatic changes in blood glucose levels immediately to prescriber and review how to treat hypoglycemia.

# citalopram hydrobromide

**Celexa**

## Class and Category

*Pharmacologic class:* Selective serotonin reuptake inhibitor (SSRI)

*Therapeutic class:* Antidepressant

## Indications and Dosages

➤ *To treat depression*

### ORAL SOLUTION, TABLETS

**Adults.** *Initial:* 20 mg daily. Increased to 40 mg daily, after 1 wk as needed. *Maximum:* 40 mg daily.

***DOSAGE ADJUSTMENT*** Dosage should not exceed 20 mg daily in patients taking concomitant cimetidine or CYP2C19 inhibitors, who are poor CYP2C19 metabolizers, who have hepatic impairment, or who are older than 60 years of age.

Route	Onset	Peak	Duration
P.O.	1 wk	Unknown	Unknown

## Mechanism of Action

Blocks serotonin reuptake by adrenergic nerves, which normally release this neurotransmitter from their storage sites when activated by a nerve impulse. This blocked

reuptake increases serotonin levels at nerve synapses, which may elevate mood and reduce depression.

## Contraindications

Hypersensitivity to citalopram or its components, pimozide therapy, use within 14 days of MAO inhibitor therapy including IV methylene blue or linezolid

## Interactions

### DRUGS

*antidepressants, buspirone, fentanyl, isoniazid, linezolid, lithium, MAO inhibitors, methylene blue, other selective serotonin reuptake inhibitors (escitalopram, fluoxetine, fluvoxamine, paroxetine, sertraline), pentamidine, selegiline, serotonin norepinephrine reuptake inhibitors (desvenlafaxine, duloxetine, milnacipran, venlafaxine), St. Johns' s Wort, tramadol, triptans, tryptophan:* Increased risk of life-threatening serotonin syndrome

*antipsychotics, Class IA and Class III antiarrhythmics, CYP2C19 inhibitors, gatifloxacin, methadone, moxifloxacin, pimozide:* Increased risk of QT prolongation and torsades de pointes

*aspirin, NSAIDs, warfarin:* Increased risk of bleeding ranging from ecchymoses to life-threatening hemorrhage

*carbamazepine:* Possibly increased clearance of citalopram

*clozapine:* Substantial increases in plasma clozapine levels

*cimetidine:* Possibly increased blood citalopram level and increased risk of QT prolongation

*CNS depressants:* Possible potentiated CNS effect

*diuretics:* Possibly increased risk of hyponatremia

*ketoconazole:* Decreased peak concentrations of ketoconazole

*metoprolol, tricyclic antidepressants such as desipramine or imipramine: Possibly increased blood levels of these drugs; possibly life-threatening serotonin syndrome*

## **Adverse Reactions**

**CNS:** Agitation, akathisia, amnesia, anxiety, apathy, asthenia, confusion, **CVA**, delirium, depression, dizziness, drowsiness, dyskinesia, fatigue, fever, impaired concentration, insomnia, migraine, myoclonus, **neuroleptic malignant syndrome**, paresthesia, **seizures**, **serotonin syndrome**, **suicidal ideation**, tremor

**CV:** Angina, bundle branch block, chest pain, **heart failure**, **MI**, orthostatic hypotension, **prolonged QT interval**, tachycardia, **thrombosis**, **ventricular arrhythmias**

**EENT:** Abnormal accommodation, acute-angle glaucoma, blurred vision, dry mouth, rhinitis, sinusitis, taste perversion

**GI:** Abdominal pain, anorexia, diarrhea, flatulence, **GI bleeding**, **hepatic necrosis**, indigestion, nausea, **pancreatitis**, vomiting

**GU:** **Acute renal failure**, amenorrhea, anorgasmia, decreased libido, dysmenorrhea, ejaculation disorders, impotence, polyuria, priapism

**HEME:** Abnormal bleeding, **decreased PT**, **hemolytic anemia**, **thrombocytopenia**

**MS:** Arthralgia, myalgia, **rhabdomyolysis**

**RESP:** Cough, upper respiratory tract infection

**SKIN:** Diaphoresis, ecchymosis, **erythema multiforme**, pruritus, rash

**Other:** Anaphylaxis, angioedema, hyponatremia, weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm if given late in the third trimester evident as early as immediately after birth with neonate exhibiting constant crying and irritability, feeding difficulty, temperature instability, respiratory distress and/or seizures.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

**WARNING** Monitor patient for possible serotonin syndrome, when dosage increases and which may include agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. In its most severe form, serotonin syndrome can resemble neuroleptic malignant syndrome, which includes a high fever, muscle rigidity, or autonomic instability with possible changes in vital signs, and mental status changes.

- Be aware that citalopram should not be given to patients with congenital long QT syndrome, bradycardia, hypokalemia or hypomagnesemia, recent acute myocardial infarction, or uncompensated heart failure because of

increased risk of prolonged QT interval and torsades de pointes. It should also not be given to patients who are taking other drugs that prolong the QT interval. Expect hypokalemia and hypomagnesemia to be corrected before citalopram therapy is begun.

- Use citalopram cautiously in patients with other cardiac conditions. ECG monitoring may be ordered to monitor the patient's QT interval and detect the development of serious arrhythmias.
- Use citalopram cautiously in patients with hepatic impairment because citalopram clearance is affected and can lead to increased plasma citalopram levels.
- Be aware that effective antidepressant therapy may convert depression into mania in predisposed people. If patient develops symptoms of mania, notify prescriber immediately and expect to discontinue citalopram.
- Assess elderly patients and those taking diuretics for signs suggesting syndrome of inappropriate secretion of antidiuretic hormone, including hyponatremia and increased serum and urine osmolarity.
- Monitor patient closely for suicidal tendencies, especially when therapy starts or dosage changes, because depression may worsen at these times.
- Expect to reduce dosage gradually when drug is no longer needed to avoid serious adverse reactions.

## **PATIENT TEACHING**

- Inform patient that citalopram's full effects may take up to 4 weeks.
- Advise patient not to self-medicate for allergies colds, or coughs without consulting prescriber because these preparations can increase the risk of adverse reactions.
- Caution patient not to stop citalopram abruptly because doing so may lead to serious adverse reactions.
- Urge caregivers to monitor patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Caution against taking OTC aspirin, NSAIDs, or other remedies (including herbal products, such as St. John's wort) while taking citalopram because they may increase the risk of bleeding.
- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute closure glaucoma. Encourage patient to have an eye exam before starting therapy to see if he is at risk.

- Urge patient to report sudden, severe, or unusual adverse reactions promptly to prescriber. Although uncommon, life-threatening adverse effects may occur.

## cladribine

### Mavenclad

## Class and Category

*Pharmacologic class:* Purine antimetabolite

*Therapeutic class:* Antineoplastic

## Indications and Dosages

- *To treat relapsing forms of multiple sclerosis (MS), to include relapsing-remitting disease and active secondary progressive disease, in patients who have had an inadequate response to, or are unable to tolerate, an alternate drug indicated for the treatment of MS*

### **TABLETS**

**Adults.** 3.5 mg/kg divided into 2 yearly treatment courses (1.75 mg/kg/treatment course with each treatment course further divided into 2 treatment cycles). First course/first cycle is begun at any time, followed by first course/second cycle administered 23 to 27 days after last dose of first course/first cycle. Second course/first cycle administered at least 43 wk after last dose of first course/second cycle. Second course/second cycle administered 23 to 27 days

after last dose of second course/first cycle. Administer each cycle dosage as 1 or 2 10-mg tablets once daily, with dosage divided and given over 4 or 5 consecutive days. Do not administer more than 20 mg once daily. Dosage based on weight as follows:

**For adults weighing 110 kg and above (242 lb).** 100 mg for cycle one and 100 mg for cycle two.

**For adults weighing 100 kg (220 lb) to less than 110 kg (242 lb).** 100 mg for cycle one and 90 mg for cycle two.

**For adults weighing 90 kg (198 lb) to less than 100 kg (220 lb).** 90 mg for cycle one and 80 mg for cycle two.

**For adults weighing 80 kg (176 lb) to less than 90 kg (198 lb).** 80 mg for cycle one and 70 mg for cycle two.

**For adults weighing 70 kg (154 lb) to less than 80 kg (176 lb).** 70 mg for cycle one and 70 mg for cycle two.

**For adults weighing 60 kg (132 lb) to less than 70 kg (154 lb).** 60 mg for cycle one and 60 mg for cycle two.

**For adults weighing 50 kg (110 lb) to less than 60 kg (132 lb).** 50 mg for cycle one and 50 mg for cycle two.

**For adults weighing 40 kg (88 lb) to less than 50 kg (110 lb).** 40 mg for cycle one and 40 mg for cycle two.

## **Mechanism of Action**

May involve cytotoxic effects on B and T lymphocytes through impairment of DNA synthesis, resulting in depletion of lymphocytes.

## **Contraindications**

Active chronic infections such as hepatitis or tuberculosis, breastfeeding (avoid for 10 days following last dose), HIV infection, hypersensitivity to cladribine or its components, current malignancy, patient of reproductive potential who does not plan to use effective contraception during cladribine therapy and for 6 months after last dose in each treatment course, pregnancy

## Interactions

### DRUGS

*antiviral and antiretroviral drugs such as lamivudine, ribavirin, stavudine, zalcitabine, zidovudine:* Possible interference with cladribine effectiveness

*hematotoxic drugs:* Increased risk of serious adverse reactions because of additive hematological effects

*immunomodulatory, immunosuppressive, myelosuppressive drugs:* Increased risk of serious adverse reactions because of additive effects on immune system

*interferon-beta:* Possibly increased lymphopenia risk

*potent BCRP CNT, ENT transporter inhibitors such as cilostazol, curcumin, cyclosporine, dilazep, dipyridamole, eltrombopag, nifedipine, reserpine, ritonavir, sulindac:* Possible alteration of bioavailability, intracellular distribution, and renal elimination of cladribine *potent BCRP and P-gp transporter inducers:* Possible decreased exposure of cladribine, decreasing effectiveness

## Adverse Reactions

**CNS:** Depression, fever, headache, insomnia, **seizures**, vertigo

**CV:** **Cardiac failure**, hypertension

**EENT:** Diplopia, mucous membrane ulceration, oral herpes, **throat swelling**

**GI:** **Activation of latent hepatitis infections**, anorexia, elevated bilirubin and liver enzymes, **fulminant hepatitis**, jaundice, nausea

**GU:** Pyelonephritis

**HEME:** Anemia, **decreased platelet count**, **lymphopenia**, **neutropenia**, **pancytopenia**, **thrombocytopenia**

**MS:** Arthralgia, back pain

**RESP:** Bronchitis, upper respiratory infection

**SKIN:** Alopecia, dermatitis, pruritus, rash

**Other:** Bacterial, fungal, herpes viral, opportunistic, tuberculosis infections; **hypersensitivity reactions**; **malignancies**

## Childbearing Considerations

### PREGNANCY

- A negative pregnancy test must be obtained before drug therapy begins.
- Drug causes fetal harm.
- Drug is contraindicated during pregnancy.
- If pregnancy occurs during treatment, drug is discontinued.

### LACTATION

- It is not known if drug is present in breast milk.
- Drug is contraindicated in breastfeeding women.

## REPRODUCTION

- Patients of reproductive potential must use effective contraception during cladribine therapy and for 6 months after last dose in each treatment course.
- Instruct female patients of childbearing age to immediately report suspected or confirmed pregnancy to prescriber.
- Women using systemically acting hormonal contraceptives need to add a barrier method during cladribine therapy and for at least 4 weeks after last dose in each treatment course, because it is unknown if drug may reduce effectiveness of hormonal contraceptives.

## Nursing Considerations

- Know that cladribine is not recommended for patients with clinically isolated syndrome, because drug is deemed unsafe.

**WARNING** Be aware that cladribine may increase the risk of malignancy and is contraindicated in patients who currently have a malignancy. Expect patient to be screened for cancer before cladribine therapy begins and follow standard cancer screening guidelines during and after drug therapy.

- Ensure that all women of childbearing age have had a negative pregnancy test prior to cladribine therapy, because drug can cause fetal harm.
- Obtain a complete blood count, including lymphocyte count, before cladribine therapy begins. Lymphocytes must be within normal limits before initiating first treatment course and at least 800 cells/microliter before initiating second treatment course. Second treatment course may have to be delayed for up to 6 months to allow for recovery of lymphocytes to at least 800 cells/microliter. However, if recovery takes longer than 6 months, expect drug to be discontinued.
- Assess patient for the presence of infection prior to starting cladribine therapy. This includes evaluating patient for acute infection (cladribine therapy may have to be delayed until infection is under control), excluding presence of hepatitis B and C and HIV infections (screen for hepatitis B and C before first and second treatment courses), tuberculosis screening

(before first and second treatment courses), and varicella zoster virus screening (vaccination for patients who are antibody-negative).

- Expect to obtain a baseline (within 3 months) magnetic resonance imaging prior to first treatment course because of risk of progressive multifocal leukoencephalopathy (PML) and assess alkaline phosphatase, total bilirubin, and serum aminotransferase levels prior to starting cladribine therapy.
- Administer all immunizations, as ordered, according to immunization guidelines prior to starting cladribine therapy. Expect to administer live-attenuated or live vaccines at least 4 to 6 weeks prior to starting drug therapy.
- Be aware that following the administration of two treatment courses, drug should not be administered during the next two years because of risk of malignancy.
- Administer all oral drugs at least 3 hours before or after administering cladribine to prevent drug interactions.
- Know that cladribine is a cytotoxic drug and requires special handling and disposal procedures. Once removed from the blister, tablet must be swallowed immediately. If tablet is left on a surface or if a broken or fragmented tablet is released from the blister, area must be thoroughly washed with water.
- Avoid contact with skin. Follow protocol if contact occurs.
- Expect to administer antiherpes prophylaxis in patients with lymphocyte counts less than 200 cells/microliter, as ordered.
- Ensure that complete blood counts with differential, including lymphocyte count, are performed as follows: before initiating first course, before initiating second course, 2 to 3 months after starting treatment in each treatment course (if lymphocyte count at month 2 is below 200 cells/microliter, expect monthly monitoring until month 6), and periodically thereafter and when clinically indicated.
- Withhold drug after consulting with prescriber if lymphocyte count is below 200 cells/microliter.
- Monitor patient for signs and symptoms of infection throughout drug therapy, especially if lymphocyte count is below 500 cells/microliter. Know that infections occur in about half of patients, with the most serious being herpes zoster and pyelonephritis. At first sign of infection, notify prescriber, because drug therapy may have to be delayed or interrupted. Institute infection control measures.
- Monitor patient for liver dysfunction such as abdominal pain, anorexia, dark urine, fatigue, jaundice, unexplained nausea, or vomiting. If present,

notify prescriber and expect liver enzymes to be obtained. If elevated, expect drug to be interrupted or discontinued.

- Monitor patient for hypersensitivity reactions such as dermatitis and pruritus. Serious reactions can occur involving diplopia, headache, rash, and throat swelling. Stop cladribine immediately and notify prescriber. Provide supportive emergency care according to protocol, as prescribed.
- Monitor patient for heart failure such as edema, irregular or rapid heartbeat, or shortness of breath, because cladribine may induce heart failure.

**WARNING** Monitor patient for signs and symptoms of progressive multifocal leukoencephalopathy (PML), such as changes in memory, orientation, or thinking leading to confusion and personality changes, as well as clumsiness of limbs, progressive weakness on one side of the body, and visual disturbances. Although no reports of PML have occurred with cladribine for treating relapsing forms of MS, it is a possibility. At first sign of PML, notify prescriber, expect cladribine to be withheld, and ensure that appropriate diagnostic evaluation is done. Know that MRI findings may reveal problems before clinical signs or symptoms appear.

- Be aware that if patient requires a blood transfusion, irradiation of cellular blood components is recommended, prior to administration, to decrease risk of transfusion-related graft-versus-host disease. Expect a hematologist to be consulted.

## **PATIENT TEACHING**

- Stress importance of taking cladribine exactly as prescribed. If a dose is missed, tell patient not to double next dose or take extra doses. Instead, the patient should take the missed dose on the following day and extend the number of days in that treatment cycle. If two consecutive doses are missed, treatment cycle is extended by 2 days.
- Instruct patient to take tablets with water and swallow them whole without chewing or crushing them. Inform patient that drug may be taken with or without food.

- Tell patient to separate taking cladribine from ingestion of all other oral drugs by at least 3 hours during the 4- or 5-day treatment cycles.
- Instruct patient that once tablet is removed from the blister, tablet must be swallowed immediately. If tablet is left on a surface or if a broken or fragmented tablet is released from the blister, area must be thoroughly washed with water. Patient must have dry hands when handling tablets and hands must be washed thoroughly afterward. Tell patient to avoid contact with skin.
- Tell patient to notify prescriber immediately if edema, irregular or rapid heartbeat, or shortness of breath occurs.

**WARNING** Tell men and women of reproductive potential to use effective contraception during cladribine therapy and for 6 months after the last dose in each treatment course. Stress importance of informing prescriber immediately if pregnancy is suspected or confirmed, as drug must be discontinued.

- Inform women using systemically acting hormonal contraceptives to add a barrier method during cladribine therapy and for at least 4 weeks after the last dose in each treatment course, because it is unknown if drug may reduce effectiveness of hormonal contraceptives.

## clarithromycin

**Biaxin, Biaxin XL**

### Class and Category

*Pharmacologic class:* Macrolide

*Therapeutic class:* Antibiotic

### Indications and Dosages

- *To treat pharyngitis and tonsillitis caused by Streptococcus pyogenes*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 250 mg every 12 hr for 10 days.

**Children.** 15 mg/kg daily in divided doses every 12 hr for 10 days. *Maximum:* 250 mg every 12 hr.

- *To treat acute maxillary sinusitis caused by Haemophilus influenzae, Moraxella catarrhalis, or Streptococcus pneumoniae*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 500 mg every 12 hr for 14 days.

**Children.** 15 mg/kg daily in divided doses every 12 hr for 10 days. *Maximum:* 500 mg every 12 hr.

## **E.R. TABLETS**

**Adults.** 1,000 mg every 24 hr for 14 days.

- *To treat acute exacerbations of chronic bronchitis caused by H. influenzae, H. parainfluenzae, M. catarrhalis, or S. pneumoniae*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 250 to 500 mg every 12 hr for 7 to 14 days (7 days for *H. parainfluenzae*).

## **E.R. TABLETS**

**Adults.** 1,000 mg every 24 hr for 7 days.

- *To treat uncomplicated skin and soft-tissue infections caused by Staphylococcus aureus or S. pyogenes*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 250 mg every 12 hr for 7 to 14 days.

**Children.** 15 mg/kg daily in divided doses every 12 hr for 10 days. *Maximum:* 250 mg every 12 hr.

- *To treat community-acquired pneumonia caused by Chlamydia pneumoniae, Mycoplasma pneumoniae, or S. pneumoniae*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 250 mg every 12 hr for 7 to 14 days.

**Children.** 15 mg/kg daily in divided doses every 12 hr for 10 days. *Maximum:* 250 mg every 12 hr.

- *To treat community-acquired pneumonia caused by H. influenzae*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 250 mg every 12 hr for 7 days.

## **E.R. TABLETS**

**Adults.** 1,000 mg every 24 hr for 7 days.

- *To treat community-acquired pneumonia caused by H. parainfluenzae or M. catarrhalis*

## **E.R. TABLETS**

**Adults.** 1,000 mg every 24 hr for 7 days.

- *To treat acute otitis media caused by H. influenzae, M. catarrhalis, or S. pneumoniae*

## **ORAL SUSPENSION, TABLETS**

**Children.** 15 mg/kg daily in divided doses every 12 hr for 10 days. *Maximum:* 250 mg every 12 hr.

- *To treat active duodenal ulcer caused by Helicobacter pylori*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 500 mg every 8 hr for 14 days with omeprazole 40 mg daily in the morning. Then, omeprazole continued at 20 mg daily in the morning days 15 through 28. Or, 500 mg every 12 hr for 14 days with lansoprazole 30 mg and amoxicillin 1 g every 12 hr for 10 to 14 days. Alternatively, 500 mg every 12 hr with omeprazole 20 mg and amoxicillin 1 g every 12 hr for 10 days.

- *To prevent or treat Mycobacterium avium complex in patients with HIV infection*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 500 mg every 12 hr.

**Children.** 7.5 mg/kg every 12 hr. *Maximum:* 500 mg twice daily.

***DOSAGE ADJUSTMENT*** For patient with severe renal impairment (creatinine clearance less than 30 ml/min), dosage reduced by 50%. For patient with moderate renal impairment (creatinine clearance 30 to 60 ml/min) who is also taking atazanavir or ritonavir, dosage reduced by 50%. For patient with severe renal impairment (creatinine clearance less than 30 ml/min) who is also taking atazanavir or ritonavir, dosage reduced by 75%.

## **Mechanism of Action**

Inhibits RNA-dependent protein synthesis in many types of aerobic, anaerobic, gram-negative, and gram-positive bacteria. By binding with the 50S ribosomal subunit of the bacterial 70S ribosome, clarithromycin causes bacterial cells to die.

# Contraindications

Concurrent therapy with cisapride, colchicine (in patients with renal or hepatic impairment), dihydroergotamine, ergotamine, lomitapide, lovastatin, pimozide, or simvastatin; history of cholestatic jaundice or hepatic dysfunction; hypersensitivity to clarithromycin, erythromycin, or any macrolide antibiotic or their components

# Interactions

## DRUGS

*alfentanil, bromocriptine, cilostazol, cyclosporine, methylprednisolone, phenobarbital, St. John's wort, tacrolimus, vinblastine*: Possibly increased risk of adverse reactions

*alprazolam, midazolam (oral), triazolam*: Possibly increased effects of these triazolobenzodiazepines, including increased and/or prolonged sedation

*antiarrhythmics such as amiodarone, disopyramide, dofetilide, procainamide, quinidine, sotalol*: Increased risk of prolonged QT interval, torsades de pointes, or other life-threatening arrhythmias

*atazanavir, ritonavir*: Increased clarithromycin levels  
*calcium channel blockers*: Increased risk of acute kidney dysfunction and hypotension, especially in patients 65 years or older

*carbamazepine, other drugs metabolized by cytochrome P450 enzyme system, tolterodine*: Increased blood levels of these drugs

*cisapride, pimozide*: Increased risk of cardiac arrhythmias

*colchicine*: Increased risk of colchicine toxicity

*colchicine*: Increased risk of life-threatening colchicine toxicity

*digoxin*: Increased serum digoxin level, increasing risk of toxicity

*dihydroergotamine, ergotamine*: Risk of acute ergot toxicity

*disopyramide*: Hypoglycemia, increased risk of torsades de pointes

*efavirenz, nevirapine, rifampicin, rifabutin, rifapentine*: Decreased concentration of clarithromycin with decreased effectiveness

*hexobarbital, phenytoin, valproate*: Increased risk of adverse reactions

*insulin, oral hypoglycemics such as nateglinide,*

*pioglitazone, repaglinide, rosiglitazone*: Increased risk of severe hypoglycemia

*itraconazole*: Increased plasma concentration of clarithromycin and itraconazole with increased risk of adverse reactions that may become prolonged

*lomitapide*: Markedly increased transaminases levels

*maraviroc*: Possibly increased maraviroc exposure, resulting in increased risk of adverse reactions

*nifedipine*: Potential for hypotension and peripheral edema

*omeprazole*: Increased clarithromycin concentrations in gastric tissue and mucus

*oral anticoagulants*: Potentiated anticoagulant effects

*quetiapine*: Increased quetiapine exposure and related toxicity

*rifabutin*: Decreased clarithromycin serum levels, increased rifabutin serum levels, increased risk of uveitis

*sildenafil, tadalafil, vardenafil*: Possibly increased exposure of these phosphodiesterase inhibitors

*statins such as atorvastatin, lovastatin, pravastatin,*

*simvastatin*: Increased risk of rhabdomyolysis

*theophylline*: Increased blood theophylline level

*tolterodine*: Significant increase in tolterodine level in patients with a deficiency in CYP2D6 activity

*verapamil*: Increased risk of bradyarrhythmias, hypotension, and lactic acidosis

*zidovudine*: Decreased blood zidovudine level

## Adverse Reactions

**CNS:** Anxiety, confusion, disorientation, dizziness, fatigue, hallucinations, headache, insomnia, mania, nightmares, **seizures**, somnolence, tremor, vertigo

**CV:** **Prolonged QT interval, ventricular arrhythmias**

**EENT:** Altered smell, altered taste, glossitis, hearing loss, oral moniliasis, stomatitis, tinnitus, tongue or tooth discoloration

**ENDO:** **Hypoglycemia**

**GI:** Abdominal pain, anorexia, **cholestatic hepatitis**, diarrhea, elevated liver enzymes, **hepatic dysfunction, hepatitis, hepatotoxicity**, indigestion, jaundice, nausea, **pancreatitis, pseudomembranous colitis**, vomiting

**GU:** Elevated BUN level

**HEME:** **Increased prothrombin time, leukopenia, neutropenia, thrombocytopenia**

**MS:** **Rhabdomyolysis**

**SKIN:** Acute generalized exanthematous pustulosis, Henoch-Schönlein purpura, pruritus, rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis, angioedema, drug reaction with eosinophilia and systemic symptoms (DRESS)**, new or worsening myasthenia gravis symptoms, superinfection

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus and if no alternative therapy is available.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Expect to obtain a specimen for culture and sensitivity tests before giving first dose.
- Know that clarithromycin therapy should be avoided in patients at risk for QT prolongation such as uncorrected hypokalemia or hypomagnesemia or significant bradycardia, and in patients receiving Class IA or Class III antiarrhythmias. Elderly patients are more susceptible to clarithromycin's effect on the QT interval, as well.

**WARNING** Be aware that use of clarithromycin in patients with coronary artery disease is not recommended because of an increased risk of heart problems or death that may occur even years after exposure to drug.

- Use clarithromycin cautiously in patients with renal impairment. Be aware that patients with severe renal impairment may need decreased dosage.
- Monitor patient closely for acute hypersensitivity reactions such as anaphylaxis and serious skin disorders. If present, expect clarithromycin therapy to be discontinued immediately and appropriate emergency treatment initiated.

- Monitor patient for signs and symptoms of liver dysfunction, especially hepatitis (anorexia, dark urine, jaundice, pruritus, or tender abdomen). Notify prescriber immediately if present, and expect clarithromycin to be discontinued.
- Monitor patients with diabetes who are also receiving insulin or oral hypoglycemics closely for hypoglycemia, which could be severe.
- Be watchful for an elevated INR and prothrombin time in patients who are also taking warfarin, as serious bleeding may occur.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold clarithromycin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

## PATIENT TEACHING

- Emphasize importance of taking the full course of clarithromycin exactly as prescribed, even after feeling better, because skipped doses or not completing the full course prescribed may hinder drug from eliminating the bacterial infection and increases risk of bacterial resistance.
- Caution patient not to chew or crush E.R. tablets.
- Advise patient to take drug with food if he takes E.R. tablets or has GI distress.
- Instruct patient taking suspension form not to refrigerate it.
- Tell patient to report itching, rash, severe nausea, or any other persistent, severe, or unusual reaction to prescriber immediately.
- Instruct patient not to take OTC or prescription drugs without consulting prescriber of clarithromycin.
- Urge patient to report bloody, watery stools to prescriber immediately, even if they occur 2 months or more after therapy has ended.
- Advise patient to report signs and symptoms of liver dysfunction immediately to prescriber.
- Instruct patient not to perform hazardous activities such as driving until effects on the nervous system such as confusion and dizziness are known.
- Instruct patient with diabetes who is also taking insulin or an oral hypoglycemic agent to monitor his blood glucose level closely.

**WARNING** Advise patient who has coronary artery disease to continue lifestyle modifications and medications for the heart condition, because clarithromycin may be associated with increased risk for worsening heart problems or mortality years after the end of clarithromycin therapy. Review signs and symptoms of heart disease with all patients, because some patients may not know coronary artery disease is present. Emphasize importance of reporting such signs and symptoms to prescriber even if it is years after exposure to clarithromycin.

- Advise women of childbearing age to use contraception throughout clarithromycin therapy, because drug may cause fetal harm.

## clindamycin hydrochloride

**Cleocin, Dalacin C (CAN)**

## clindamycin palmitate hydrochloride

**Cleocin Pediatric, Dalacin C Flavored Granules (CAN)**

## clindamycin phosphate

**Cleocin, Clindesse 2%, Dalacin C Phosphate (CAN), Evoclin**

# Class and Category

*Pharmacologic class:* Lincosamide

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat serious respiratory tract infections caused by anaerobes such as occur with anaerobic pneumonitis, empyema, and lung abscess and those caused by pneumococci, staphylococci, and streptococci; serious skin and soft-tissue infections caused by anaerobes, staphylococci, and streptococci; septicemia caused by anaerobes; intra-abdominal infections caused by anaerobes such as occur with intra-abdominal abscess and peritonitis; infections of the female pelvis and genital tract caused by anaerobes such as occur with endometritis, nongonococcal tubo-ovarian abscess, pelvic cellulitis, and postsurgical vaginal cuff infection; bone and joint infections caused by Staphylococcus aureus*

## CAPSULES, ORAL SOLUTION

**Adults and adolescents.** For serious infections, 150 to 300 mg every 6 hr; for severe infections, 300 to 450 mg every 6 hr.

**Children.** For serious infections, 8 to 16 mg/kg daily in equally divided doses three times daily or four times daily; for severe infections, 16 to 20 mg/kg/day in equally divided doses three times daily or four times daily.

## I.V. INFUSION, I.M. INJECTION

**Adults and adolescents age 16 and over.** For serious infections, 600 to 1,200 mg daily in equally divided doses twice daily to four times daily; for severe infections, 1,200 to 2,700 mg daily in equally divided doses twice daily to four times daily; for life-threatening infections, up to 4,800 mg daily in equally divided doses twice daily to four times daily. I.V. infusion given over 10 to 40 min depending on the dose. Alternatively, a rapid I.V. infusion given over 30 min for first dose followed by a continuous infusion rate that varies between 0.75/min and 1.25/min depending on the clindamycin level to be maintained. Infusion rate should not exceed 30 mg/min

**Children ages 1 month to 16 years.** 20 to 40 mg/kg daily in equally divided doses three times daily or four times daily, depending on severity of infection. I.V. infusion not to exceed 30 mg/min.

**Neonates less than age 1 month.** 15 to 20 mg/kg daily in equally divided doses three times daily or four times daily, depending on severity of infection. I.V. infusion not to exceed 30 mg/min.

- *To treat bone and joint infections caused by Staphylococcus aureus; as adjunct therapy in chronic bone and joint infections*

## **I.V. INFUSION, I.M. INJECTION**

**Adults and adolescents age 16 and over.** *For serious infections:* 600 to 1,200 mg daily in equally divided doses twice daily to four times daily. *For severe infections:* 1,200 to 2,700 mg daily in equally divided doses twice daily to four times daily. *For life-threatening infections:* 4,800 mg daily in equally divided doses twice daily to four times daily. I.V. infusion not to exceed 30 mg/min.

- *To treat vaginal infections caused by anaerobes, Corynebacterium, Gardnerella or Haemophilus*

## VAGINAL CREAM

**Nonpregnant females.** 100 mg (1 applicatorful) into vagina daily, preferably at bedtime, for 3 to 7 consecutive days.

**Pregnant females in second or third trimester.** 100 mg (1 applicatorful) into vagina daily, preferably at bedtime, for 7 consecutive days.

## VAGINAL CREAM (CLINDESSE 2%)

**Nonpregnant females.** 5 g (1 applicatorful) into vagina as a single dose.

➤ *To treat acne vulgaris*

## FOAM (EVOCLIN)

**Adults and adolescents.** Apply to affected area daily, using enough to cover the entire affected area(s).

## Mechanism of Action

Inhibits protein synthesis in susceptible bacteria by binding to the 50S subunits of bacterial ribosomes and preventing peptide bond formation, which causes bacterial cells to die.

## Incompatibilities

To prevent physical incompatibility, don't administer with aminophylline, ampicillin, barbiturates, calcium gluconate, magnesium sulfate, or phenytoin.

## Contraindications

Hypersensitivity to clindamycin or any of its components

# Interactions

## DRUGS

*CYP3A4 and CYP3A5 inducers:* Possibly decreased plasma concentrations of clindamycin decreasing its effectiveness

*CYP3A4 and CYP3A5 inhibitors:* Possibly increase plasma concentrations of clindamycin with potential for adverse reactions

*erythromycin:* Possibly blocked access of clindamycin to its site of action

*kaolin-pectin antidiarrheals:* Decreased absorption of oral clindamycin

*neuromuscular blockers:* Increased neuromuscular blockade

## Adverse Reactions

**CNS:** Fatigue, headache

**CV:** **Hypotension**, thrombophlebitis (after I.V. injection)

**EENT:** Eye pain (topical), glossitis, metallic or unpleasant taste (with high I.V. doses), stomatitis

**GI:** Abdominal pain, ***Clostridium difficile*-associated diarrhea**, diarrhea, elevated liver enzymes, esophagitis, jaundice, nausea, **pseudomembranous colitis**, vomiting

**GU:** Cervicitis, renal dysfunction, vaginitis, and vulvar irritation (with vaginal form)

**HEME:** **Agranulocytosis**, eosinophilia, **leukopenia**, **neutropenia**, **thrombocytopenic purpura**

**MS:** Polyarthrititis

**SKIN:** Acute generalized exanthematous pustulosis, contact dermatitis (topical), **erythema multiforme**,

**exfoliative dermatitis**, irritation, maculopapular rash, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis; angioedema; drug reaction with eosinophilia and systemic symptoms (DRESS);** induration, pain, or sterile abscess after injection; superinfection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug should be used with caution during pregnancy, especially during the first trimester, only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- An alternative drug should be substituted if breastfeeding occurs. If this is not possible, infant should be monitored for blood in the stool, diarrhea, and candidiasis (thrush, diaper rash).

## Nursing Considerations

- Expect to obtain a specimen for culture and sensitivity testing before giving first dose.
- Use clindamycin cautiously in patients who have a history of asthma, GI disease, or significant allergies; in those with hepatic or renal dysfunction; and in atopic or elderly patients.

**WARNING** Don't give 75- and 150-mg capsules to tartrazine-sensitive patients.

- Store oral solution for up to 2 weeks at room temperature or reconstituted parenteral solution for up to 24 hours at room temperature.
- Give I.V. dose by infusion only. If given as an intermittent I.V. infusion for each dose, dilute and administer as follows: dilute 300 mg of clindamycin in 50 ml of diluent and give over 10 minutes. Dilute 600 mg of clindamycin in 50 ml of diluent and give over 20 minutes. Dilute 900 mg of clindamycin in 50 to 100 ml of diluent and give over 30 minutes. Dilute 1,200 mg of clindamycin in 100 ml of diluent and give over 40 minutes. Alternatively, first dose may be given as a rapid infusion over 30 minutes, followed by a continuous infusion with rate determined by clindamycin level to be maintained. Regardless of how the drug is administered as an I.V. infusion, the rate should not exceed 30 mg/min. A single IV infusion dose greater than 1,200 mg is not recommended.

**WARNING** Don't use diluents that contain benzyl alcohol when clindamycin is to be administered to neonates because a fatal toxic syndrome may occur.

- Do not dilute clindamycin phosphate prior to administering I.M. Give I.M. injection deep into large muscle mass, such as the gluteus maximus. Rotate injection sites, and avoid giving more than 600 mg in a single I.M. injection.
- Check I.V. site often for phlebitis and irritation.
- For topical foam, wash the affected area with mild soap, let it dry fully, and then apply foam to entire affected area. Be aware that if dermatitis or irritation develops, notify prescriber as foam will need to be discontinued.
- Monitor results of CBC, liver enzymes, and platelet counts during prolonged therapy.
- Observe patient for signs and symptoms of superinfection, such as sore mouth and vaginal itching, which may occur 2 to 9 days after therapy begins.
- Assess patient's skin regularly for abnormalities because clindamycin may cause severe skin reactions. If present, notify prescriber, expect drug to be discontinued, and be prepared to administer supportive treatment, as prescribed.
- Assess patient's bowel pattern daily; severe diarrhea may indicate pseudomembranous colitis caused by *C. difficile*. If diarrhea occurs, notify prescriber and expect to withhold clindamycin and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

# PATIENT TEACHING

- Tell patient to complete the prescribed course of therapy, even if he feels better before it's finished.
- Instruct patient to take clindamycin capsule with at least 8 ounces of water to prevent esophageal irritation.
- Advise patient to take oral drug with food, if needed, to reduce GI distress.
- Tell patient not to refrigerate reconstituted oral solution because it may become thick and difficult to pour and to discard unused drug after 14 days.
- Tell patient using topical foam to wash affected area with mild soap, let it dry fully, and then apply foam to entire area. Caution against dispensing foam directly onto hands or face because foam will melt when it contacts warm skin. Instead, patient should dispense amount to be used into the cap or onto a cool surface. Tell patient to pick up a small amount with fingertips and gently massage into affected area until foam disappears. If foam feels warm or looks runny, tell patient to run the can under cold water before dispensing.
- Advise patient using topical foam to avoid contact with eyes, lips, mouth, other mucous membranes or areas of broken skin. If contact occurs, tell patient to rinse area thoroughly with water.
- Warn patient not to rely on latex or rubber condoms and diaphragms for 72 hours after vaginal treatment because mineral oil in vaginal cream may weaken these items.
- Explain that having sexual intercourse after using vaginal cream can increase irritation.
- Inform patient that I.M. injection may be painful.
- Tell patient to immediately report an inflamed mouth or vagina, and lesions or rash. Also tell patient to immediately report any skin abnormalities such as rash, pruritus, or urticaria.
- Urge patient to report bloody, watery stools to prescriber immediately, even up to 2 months after drug therapy has ended.
- Advise mothers not to breastfeed because drug does appear in breast milk and cause adverse gastrointestinal effects for infant.

# clobazam

**Onfi, Sympazan**

## Class and Category

*Pharmacologic class:* Benzodiazepine

*Therapeutic class:* Anticonvulsant

*Controlled substance schedule:* IV

## Indications and Dosages

- *Adjunct treatment of seizures associated with Lennox-Gastaut syndrome*

### **ORAL DISSOLVING FILM STRIPS, ORAL SUSPENSION, TABLETS**

**Adults and children age 2 and over weighing more than 30 kg (66 lb).** *Initial:* 5 mg twice daily increased to 10 mg twice daily on day 7 and further increased to 20 mg twice daily on day 14. *Maximum:* 40 mg daily.

**Adults and children age 2 and over weighing less than or equal to 30 kg (66 lb).** *Initial:* 5 mg once daily increased to 5 mg twice daily on day 7 and further increased to 10 mg twice daily on day 14. *Maximum:* 20 mg daily.

***DOSAGE ADJUSTMENT*** For elderly patients and patients who are CYP2C19 poor metabolizers or those with hepatic dysfunction, initial dose begun at 5 mg once daily regardless of weight and then titrated according to weight, but only to half the dose normally given for weight

category. If needed, an additional titration to the maximum dose for the patient's weight may be started on day 21.

## **Mechanism of Action**

May possibly involve potentiation of GABAergic neurotransmission, which causes binding at the benzodiazepine site of the GABA<sub>A</sub> receptor to stop seizure activity.

## **Contraindications**

Hypersensitivity to clobazam or its components

## **Interactions**

### **DRUGS**

*benzodiazepines, opioids*: Increased risk of significant respiratory depression

*CNS depressants, opioids, other benzodiazepines, sedating antihistamines, tricyclic antidepressants*: Increased risk of significant sedation and somnolence

*fluconazole, fluvoxamine, ticlopidine and other strong inhibitors of CYP2C19 and omeprazole, a moderate inhibitor of CYP2C19 drugs*: Increased action of clobazam and adverse effects

*CYP2D6 drugs*: Possibly altered metabolism of these drugs  
*midazolam*: Decreased effect of midazolam

*opioids*: Increased risk of significant respiratory depression

*oral contraceptives*: Possible diminished effectiveness of oral contraceptive

### **ACTIVITIES**

*alcohol use:* Additive CNS effect including severe respiratory depression and significant sedation and somnolence; increased effect of clobazam

## Adverse Reactions

**CNS:** Aggression, agitation, anxiety, apathy, ataxia, confusion, depression, delirium, delusion, fatigue, hallucination, insomnia, irritability, lethargy, psychomotor hyperactivity, pyrexia, sedation, somnolence, **suicidal ideation**

**EENT:** Blurred vision, diplopia, drooling

**GI:** Abdominal distention, change in appetite, constipation, dysphagia, elevated liver enzymes, vomiting

**GU:** UTI

**HEME:** Anemia, eosinophilia, **leukopenia**, **thrombocytopenia**

**MS:** Dysarthria, muscle spasms

**RESP:** Bronchitis, cough, pneumonia, **respiratory depression**, upper respiratory infection

**SKIN:** Rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** Physical and psychological dependence

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.

- Drug can cause fetal harm if administered late in pregnancy possibly causing neonatal abstinence syndrome and withdrawal that can occur within hours to weeks after birth and persist for hours to months.
- Drug should be used with caution during pregnancy, especially in third trimester, only if benefit to mother outweighs potential risk to fetus.

## LABOR & DELIVERY

- Administration of benzodiazepines such as clobazam immediately prior to or during childbirth can cause floppy infant syndrome, which can last up to 14 days.
- Drug is not recommended during labor and delivery.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding takes place, advise mother to monitor infant for drowsiness and poor sucking.

## Nursing Considerations

- Watch for signs of physical and psychological dependence (strong desire or need to increase dose to maintain drug effects), especially in patients with a history of substance abuse. Alert prescriber, if present.

**WARNING** Be aware that benzodiazepine therapy like clobazam should only be used concomitantly with opioids in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of the opioid to be limited. Monitor patient closely for signs and symptoms of decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber

immediately and provide emergency supportive care, as death may occur.

- Monitor patient closely for skin reactions, especially during the first 8 weeks of therapy or when reintroducing clobazam therapy. If the patient develops a rash, notify prescriber immediately and expect drug to be discontinued, as serious dermatological adverse reactions have occurred with clobazam therapy.
- Monitor patient for suicidal tendencies, particularly when therapy starts and dosage changes.
- Expect to withdraw clobazam therapy gradually when the drug is discontinued by decreasing total daily dose by 5 to 10 mg/day on a weekly basis until discontinued, as ordered, to avoid withdrawal symptoms such as anxiety, dysphoria, and insomnia.

## **PATIENT TEACHING**

- Advise patient or parents that clobazam prescribed as a tablet may be given as a whole tablet or crushed and mixed in applesauce.
- Instruct patient prescribed oral suspension form to shake container well before every administration. The oral dosing syringe provided with the product should be the only device used to measure dosage. Tell patient to firmly insert adapter into the neck of the bottle before the first use and keep it there. To withdraw the dose, she should pull back on dosing syringe to dosage amount that will be withdrawn from bottle, insert the dosing syringe into the adapter, invert bottle, slowly push the air from the syringe into the bottle and then slowly pull back the plunger to the prescribed dose. After removing the syringe from the bottle adapter, the patient should be told to slowly squirt the suspension into the corner of her mouth. Then she should replace the cap over the adapter until next dose is due and rinse syringe well with warm water.
- Tell patient prescribed the oral dissolving film strip form to place the film on top of the tongue and allow it to dissolve. As the film dissolves, saliva should be swallowed in a normal manner, but tell patient to refrain from chewing, spitting, or talking. Although it can be taken with or without food, it should not be taken with liquids. Remind patient that only one film strip should be taken at a time. If more than one film strip is needed, patient should wait until the first film strip is dissolved before placing the second film strip on the tongue.
- Tell patient not to take more drug or more often, or for a longer time than prescribed. Warn her that physical and psychological dependence can

occur and teach her to recognize the signs.

**WARNING** Warn patient not to consume alcohol or take an opioid during clobazam therapy without prescriber knowledge, as severe respiratory depression can occur and may lead to death.

**WARNING** Inform patient about potentially fatal additive effects of combining clobazam with an opioid. Instruct patient to inform all prescribers of clobazam use, especially if an opioid pain medication may be prescribed.

- Warn patient to stop taking drug at the first sign of a rash and to notify prescriber immediately.
- Instruct patient to avoid performing hazardous activities such as driving until the effects of clobazam are known.
- Tell patient not to stop taking clobazam abruptly, as withdrawal symptoms may occur.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Inform female patient of childbearing age to discuss clobazam therapy with her prescriber because drug could interfere with the effectiveness of oral contraceptives. Additional nonhormonal forms of contraception should be used during clobazam therapy if pregnancy is not desired.
- Encourage women of childbearing age who become pregnant while taking clobazam to register with the pregnancy exposure registry by calling 1-888-233-2334. Also advise them that clobazam therapy may pose a potential risk to the fetus. Infants born to mothers who have taken benzodiazepines such clobazam during the later stages of pregnancy can develop dependence, and subsequently withdrawal, during the postnatal period.
- Advise mothers not to breastfeed while taking clobazam, because the drug is found in breast milk. If breastfeeding does occur, tell mothers to monitor the infant for poor sucking and possible sedation. If present, breastfeeding should be discontinued.

# clomipramine hydrochloride

**Anafranil**

## Class and Category

*Pharmacologic class:* Tricyclic antidepressant

*Therapeutic class:* Antiobsessional agent

## Indications and Dosages

➤ *To treat obsessive-compulsive disorder*

### CAPSULES, TABLETS

**Adults.** *Initial:* 25 mg daily with a meal. Gradually increased to 100 mg daily in divided doses over 2 wk, then to maximum of 250 mg daily in divided doses with meals over next few weeks. At maximum dose, total daily amount may be given at bedtime.

**Children age 10 and over.** *Initial:* 25 mg daily with a meal. Gradually increased to the lesser of 3 mg/kg daily or 100 mg daily in divided doses over 2 wk, then to maximum of 3 mg/kg daily or 200 mg daily with meals, whichever is less. At maximum dose, total daily amount may be given at bedtime.

Route	Onset	Peak	Duration
P.O.	Unknown	2-4 wk	Unknown

## Mechanism of Action

May inhibit neuronal reuptake of norepinephrine and serotonin, which may be a factor in normalizing neurotransmission in obsessive-compulsive behavior.

## Contraindications

Acute recovery period after MI, hypersensitivity to clomipramine or its components, linezolid or methylene blue (I.V.) administration, use of an MAO inhibitor within 14 days

## Interactions

### DRUGS

*anticholinergics, sympathomimetics:* Altered blood levels possibly requiring dosage adjustment of clomipramine  
*barbiturates, phenytoin:* Possibly decreased level and effects of clomipramine; additive CNS depression; possibly increased barbiturate effect

*cimetidine, flecainide, haloperidol, methylphenidate, other antidepressants, phenothiazines, propafenone, quinidine, H<sub>2</sub>-receptor antagonists, selective serotonin reuptake inhibitors:* Possibly increased blood level and adverse effects of clomipramine; possibly altered plasma concentrations of these drugs

*clonidine:* Antagonized antihypertensive effect of clonidine, possibly causing increased blood pressure and risk of hypertensive crisis

*CNS depressants:* Increased CNS depression

*digoxin, warfarin:* possibly increased blood levels of these drugs and adverse reactions

*guanethidine:* Antagonized antihypertensive effect of guanethidine

*MAO inhibitors:* Increased risk of coma, seizures, or death

## ACTIVITIES

*alcohol use:* Increased CNS depression

## Adverse Reactions

**CNS:** Anxiety, confusion, depersonalization, depression, dizziness, drowsiness, emotional lability, fatigue, headache, insomnia, panic reaction, paresthesia, **serotonin syndrome**, somnolence, **suicidal ideation (children and teens)**, syncope, tremor, unusual dreams, yawning

**CV:** Orthostatic hypotension, palpitations, tachycardia

**EENT:** Acute-angle glaucoma, blurred vision, dry mouth, epistaxis, pharyngitis, rhinitis, sinusitis, unpleasant taste

**ENDO:** Syndrome of inappropriate antidiuretic hormone secretion (SIADH)

**GI:** Abdominal pain, anorexia, constipation, diarrhea, flatulence, increased appetite, indigestion, nausea, vomiting

**GU:** Dysmenorrhea, ejaculation failure, impotence, urinary hesitancy, urine retention

**RESP:** **Bronchospasm**

**SKIN:** Abnormal skin odor, acne, dermatitis, dry skin, photosensitivity, rash, urticaria

**Other:** **Drug reaction with eosinophilia and systemic symptoms (DRESS)**, **hyponatremia**, weight gain

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm if administered up to time of deliver possibly causing withdrawal symptoms in neonate after birth.
- Use with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Be aware that stopping clomipramine abruptly may cause withdrawal symptoms and worsen disorder.

**WARNING** Don't give drug within 14 days of an MAO inhibitor to avoid possible coma, seizures, or possibly death.

**WARNING** Monitor patient closely for evidence of suicidal ideation; clomipramine increases the risk.

- Monitor patient for hyponatremia such as confusion, difficulty concentrating, headache, unsteadiness, and weakness. More severe reactions may present as coma, hallucinations, seizures, and syncope which can lead to respiratory arrest and death if left untreated. Hyponatremia occurs as a result of SAIDH that maybe an adverse reaction to clomipramine. Patients at greater risk are the elderly and patients taking diuretics or who are experiencing volume depletion. Notify prescriber immediately if hyponatremia occurs, expect appropriate medical treatment to raise the sodium level, and anticipate that drug will be discontinued.

**WARNING** Monitor patient closely for evidence of serotonin syndrome, such as agitation, coma, diarrhea, hallucinations, hyperreflexia, hyperthermia, incoordination, labile blood pressure, nausea, tachycardia, or vomiting. Notify prescriber at once

because serotonin syndrome maybe life-threatening. Be prepared to discontinue drug and provide supportive care.

## **PATIENT TEACHING**

- Tell patient not to use alcohol, barbiturates, or other CNS depressants; clomipramine increases their effects.

**WARNING** Urge families to watch patient closely for abnormal thinking or behavior, or increased aggression or hostility. Emphasize the need to notify prescriber if they occur.

- Inform male patients about risk of sexual dysfunction while taking drug.
- Caution patient that drug may cause drowsiness, especially during initial dosage adjustment.
- Warn patient not to stop taking drug abruptly.
- Instruct patient to take a missed dose as soon as he remembers unless it's almost time for the next scheduled dose, in which case he should skip the missed dose. Warn against doubling the next dose.
- Teach patient how to prevent photosensitivity reactions.
- Tell patient to report difficulty urinating, dizziness, dry mouth, mental changes, or sedation.
- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute-angle glaucoma. Encourage patient to have an eye exam before starting therapy to see if he is at risk.
- Caution patient to avoid hazardous activities until CNS effects of drug are known.
- Warn patient to seek medical attention if he experiences confusion, difficulty concentrating or thinking, feeling unsteady and having headaches, memory problems, or weakness.

# clonazepam

## Clonapam (CAN), Rivotril (CAN)

### Class, Category, and Schedule

*Pharmacologic class:* Benzodiazepine

*Therapeutic class:* Anticonvulsant, antipanic

*Controlled substance schedule:* IV

### Indications and Dosages

- *As adjunct or to treat Lennox-Gastaut syndrome (type of absence seizure disorder) and akinetic and myoclonic seizures*

#### ORAL DISINTEGRATING TABLETS, TABLETS

Adults and children over age 10. 1.5 mg daily in divided doses three times daily. Increased by 0.5 to 1 mg every 3 days, if needed, until seizures are **controlled**. **Maximum: 20 mg daily.**

**Children age 10 and under** or weighing 30 kg (66 lb) or less. 0.01 to 0.03 mg/kg daily in divided doses twice daily or three times daily. Increased by 0.25 to 0.5 mg every *third day* up to maintenance dosage. Maintenance: 0.1 to 0.2 mg/kg daily, preferably in three equal doses, or if unequal, largest dose given at bedtime. *To treat panic disorder*

#### ORALLY DISINTEGRATING TABLETS, TABLETS

**Adults.** *Initial:* 0.25 mg twice daily. Increased, if needed, to 1 mg daily after 3 days. If more than 1 mg daily is required,

dosage increased in increments of 0.125 to 0.25 mg twice daily every 3 days until panic disorder is controlled or adverse reactions make further increases undesirable. This maintenance dosage may be given as a single dose at bedtime. *Maximum:* 4 mg daily.

## **Mechanism of Action**

Although unknown, drug is thought to prevent panic and seizures by potentiating the effects of gamma-aminobutyric acid (GABA), which is an inhibitory neurotransmitter. This action is also thought to suppress the spread of seizure activity caused by seizure-producing foci in the cortex, limbic, and thalamus structures.

## **Contraindications**

Acute-narrow-angle glaucoma; hepatic disease; hypersensitivity to clonazepam, other benzodiazepines, or their components

## **Interactions**

### **DRUGS**

*antianxiety drugs, antipsychotics (butyrophenone and thioxanthene classes), barbiturates, CNS depressants, MAO inhibitors, narcotics, nonbarbiturate hypnotics, other benzodiazepines, phenothiazines, sedating antihistamines, tricyclic antidepressants:* Increased risk of CNS depression including significant sedation and somnolence  
*carbamazepine, lamotrigine, phenobarbital, phenytoin:* Possibly decreased plasma clonazepam levels with potential for interference with its effectiveness

*fluconazole*: Possibly impaired clonazepam metabolism with potential for exaggerated concentrations and effects

*opioids*: Increased risk of severe respiratory depression

*phenytoin*: Possibly altered plasma concentrations of phenytoin

## **ACTIVITIES**

*alcohol use*: Increased CNS depression, including severe respiratory depression and significant sedation and somnolence  
**Adverse Reactions**

**CNS:** Abnormal dreams, aggression, agitation, amnesia, anxiety, apathy, ataxia, attention disturbance, confusion, depersonalization, depression, dizziness, drowsiness, emotional lability, excessive dreaming, fatigue, hallucinations, headache, hostility, hysteria, insomnia, irritability, memory loss, nervousness, nightmares, organic disinhibition, psychosis, reduced intellectual ability, sleep disturbances, **suicidal ideation**

**CV:** Palpitations

**EENT:** Blurred vision, eyelid spasm, increased salivation, loss of taste, pharyngitis, rhinitis, sinusitis, yawning

**GI:** Abdominal pain, anorexia, constipation, increased appetite

**GU:** Altered libido, difficult ejaculation, dysmenorrhea, dysuria, enuresis, impotence, nocturia, urine retention, UTI

**HEME:** Anemia, eosinophilia, **leukopenia**, **thrombocytopenia**

**MS:** Dysarthria, myalgia

**RESP:** Bronchitis, cough, **respiratory depression**

**Other:** **Allergic reaction**

# Childbearing Considerations

## PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.
- Drug can cause fetal harm if administered late in pregnancy possibly causing neonatal abstinence syndrome or withdrawal that can occur within hours to weeks after birth and persist for hours to months.
- Drug should be used with caution during pregnancy, especially in third trimester, only if benefit to mother outweighs potential risk to fetus.

## LABOR & DELIVERY

- Administration of benzodiazepines such as clonazepam immediately prior to or during childbirth can cause floppy infant syndrome, which can last up to 14 days.
- Drug is not recommended during labor and delivery.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding takes place, advise mother to monitor infant for drowsiness and poor sucking.

# Nursing Considerations

- Use clonazepam cautiously in patients with mixed seizure disorder (because drug can increase the risk of generalized tonic-clonic seizures), renal failure, or troublesome secretions (because clonazepam increases salivation) and in elderly patients (because they're more sensitive to drug's CNS effects). Also use cautiously in patients with compromised respiratory function and porphyria.
- Monitor blood drug level, CBC, and liver enzymes during long-term or high-dose therapy, as ordered.

- Monitor patient closely for signs of loss of effectiveness of anticonvulsant activity, especially within the first 3 months of administration. Notify prescriber if noted, because a dosage adjustment may reestablish effectiveness.

**WARNING** Know that the drug should not be stopped abruptly. Instead, expect to taper dosage gradually by 0.125 mg twice daily every 3 days, until the drug is completely discontinued, to avoid withdrawal symptoms and seizures.

- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.
- Be aware that paradoxical and psychiatric reactions have occurred with benzodiazepines. Because clonazepam is a benzodiazepine, monitor patient for aggression, agitation, anger, anxiety, hallucinations, irritability, nightmares, and psychoses. Children and elderly patients are at greater risk of developing paradoxical reactions. If noted, notify prescriber and expect drug to be discontinued gradually.

**WARNING** Be aware that benzodiazepine therapy like clonazepam should only be used concomitantly with opioids in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of the opioid to be limited. Monitor patient closely for signs and symptoms of decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

- Know that although the risk of teratogenicity is inconclusive, administration of benzodiazepines like clonazepam immediately before or during childbirth can cause a syndrome of difficulty feeding, hypothermia, hypotonia, and respiratory depression in the infant after birth. Also know that if mothers have taken clonazepam during the later stages of pregnancy, their infants may develop a dependency on the drug and experience withdrawal after birth.

## PATIENT TEACHING

- Tell patient to take drug exactly as prescribed. Explain that stopping abruptly can cause seizures and withdrawal symptoms.
- Urge patient to carry medical identification of his seizure disorder and drug therapy.
- Warn patient about possible drowsiness.
- Instruct patient to report, difficulty urinating, palpitations, persistent drowsiness, seizure activity, severe dizziness, and other disruptive adverse reactions.
- Suggest that parents monitor child's performance in school because clonazepam can cause drowsiness or inattentiveness.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report concerns to prescriber immediately.

**WARNING** Warn patient not to consume alcohol or take an opioid during clonazepam therapy without prescriber *knowledge, as severe respiratory depression can occur and may lead to death.*

**WARNING** Inform patient about potentially fatal additive effects of combining clonazepam with an opioid. Instruct patient to inform all prescribers of clonazepam use, especially if pain medication may be prescribed.

- Warn women of childbearing age who become pregnant while taking clonazepam to notify prescriber of pregnancy. Tell them to discuss alternative therapy with prescriber while pregnant. Urge female patient who becomes pregnant while taking clonazepam to enroll in the Antiepileptic Drug Pregnancy Registry by calling 1-888-233-2334. Explain that the registry is studying the safety of antiepileptic drugs during pregnancy.
- Encourage mothers to discuss breastfeeding with prescriber before doing so.
- Tell patient to let prescriber know about any new drug prescribed by another healthcare provider or before using any new over-the-counter preparations.

# clonidine

## Catapres-TTS

# clonidine hydrochloride

## Catapres, Dixarit (CAN), Duraclon, Kapvay

### Class and Category

*Pharmacologic class:* Centrally acting alpha agonist

*Therapeutic class:* Analgesic, antihypertensive, behavior modifier

### Indications and Dosages

➤ *To manage hypertension*

#### **TABLETS**

**Adults.** *Initial:* 0.1 mg twice daily, increased by 0.1 mg/wk to produce desired response. *Maintenance:* 0.2 to 0.6 mg daily in divided doses twice daily or three times daily.

*Maximum:* 2.4 mg daily.

#### **TRANSDERMAL PATCH (CATAPRES-TTS)**

**Adults.** *Initial:* 0.1-mg patch applied to hairless area of intact skin on upper arm or torso every 7 days. After 1 to 2 wk, if blood pressure isn't controlled, two 0.1-mg patches or one 0.2-mg patch applied to skin. Dosage adjusted, as

needed, every 7 days. *Maximum:* Two 0.3-mg patches worn at same time.

**DOSAGE ADJUSTMENT** Dosage initially reduced for patients with renal failure.

- *To treat attention deficit hyperactivity disorder (ADHD) alone or as adjunct therapy with stimulant drugs*

## **E.R. TABLETS (KAPVAY)**

**Children age 6 to 17.** *Initial:* 0.1 mg at bedtime, increased in increments of 0.1 mg daily at weekly intervals, as needed, with total daily dosage equally divided and given twice a day with the second dose of an equal or higher split dosage given at bedtime as soon as dosage begins to be increased. *Maximum:* 0.4 mg/day.

- *As adjunct to relieve severe pain (in cancer patients) that isn't adequately relieved by opioid analgesics alone*

## **CONTINUOUS EPIDURAL INFUSION (DURACLON)**

**Adults.** *Initial:* 30 mcg/hr. Titrated up or down, if needed, depending on comfort. *Maximum:* 40 mcg/hr.

Route	Onset	Peak	Duration
P.O.	30-60 min	2-4 hr	8 hr
Trans-dermal	2-3 days	Unknown	7 days

## **Mechanism of Action**

Stimulates peripheral alpha-adrenergic receptors in the CNS to produce transient vasoconstriction and then stimulates central alpha-adrenergic receptors in the brain stem to reduce heart rate, peripheral vascular resistance,

heart rate, and systolic and diastolic blood pressure. Although  $\alpha_2$  adrenergic receptors in the brain are stimulated, the precise action that calms children with ADHD is unknown. May produce analgesia by preventing transmission of pain signals to the brain at presynaptic and postjunctional  $\alpha_2$ -adrenoreceptors in the spinal cord. With epidural administration, clonidine produces analgesia in body areas innervated by the spinal cord segments in which the drug concentrates.

## Contraindications

Anticoagulant therapy (epidural infusion); bleeding diathesis; (epidural infusion); hypersensitivity to clonidine or its components, including adhesive used in transdermal patch; injection-site infection (epidural infusion)

## Interactions

### DRUGS

*barbiturates, other CNS depressants:* Increased depressant effects of these drugs

*beta blockers, calcium channel blockers, digoxin:* Additive effects, such as bradycardia and AV block; increased risk of worsened hypertensive response when clonidine is withdrawn (beta blockers only)

*diuretics, other antihypertensive drugs:* Increased hypotensive effect

*epidural local anesthetics:* Prolonged effects of epidural local anesthetics when used with epidural clonidine

*fluphenazine:* Possible development of acute delirium

*tricyclic antidepressants:* Decreased antihypertensive effect of clonidine

## ACTIVITIES

*alcohol use:* Enhanced CNS depressant effects of alcohol

## Adverse Reactions

**CNS:** Agitation, delusional perception, depression, dizziness, drowsiness, fatigue, hallucinations, headache, malaise, nervousness, paresthesia, sedation, syncope, weakness, tremor

**CV:** **Arrhythmias**, **AV block**, **bradycardia (severe)**, chest pain, **congestive heart failure**, orthostatic hypotension, Raynaud's phenomenon

**EENT:** Accommodation disorder, blurred vision, burning eyes, decreased lacrimation, dry eyes and mouth, salivary gland pain

**GI:** Constipation, **hepatitis**, mildly elevated liver enzymes, nausea, vomiting

**GU:** Decreased libido, erectile dysfunction, nocturia

**HEME:** **Thrombocytopenia**

**SKIN:** Pruritus, rash, urticaria

**Other:** **Angioedema**, weight gain, withdrawal symptoms

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## **Nursing Considerations**

- Be aware that clonidine should not be used in most patients with severe cardiovascular disease or in those who are not hemodynamically stable because of the potential for severe hypotension.
- Use clonidine cautiously in elderly patients, who may be more sensitive to its hypotensive effect.
- Monitor blood pressure and heart rate often during clonidine therapy because clonidine may worsen AV block and sinus node dysfunction, especially if patient is taking another sympatholytic drug. If severe bradycardia occurs, be prepared to administer IV atropine or isoproterenol and assist with insertion of temporary cardiac pacing.
- Be aware that extended-release tablets are not interchangeable with immediate-release tablets.
- Expect transdermal clonidine to take 2 to 3 days to lower blood pressure.
- Remove patch before patient has an MRI to avoid possible burns at the patch site.
- Be aware that stopping drug abruptly can elevate serum catecholamine levels and cause such withdrawal symptoms as agitation, confusion headache, nervousness, rebound hypertension, and tremor. Be aware that when drug has been used to treat ADHD, dosage should be decreased by 0.1 mg every 3 to 7 days when it is being discontinued.
- Monitor patient with AV block and sinus node dysfunction closely if patient is taking sympatholytics concurrently with clonidine because these conditions may worsen, causing severe bradycardia, requiring treatment with IV atropine or isoproterenol therapy and temporary cardiac pacing.
- Expect hypertension to return within 48 hours after drug is discontinued.

## **PATIENT TEACHING**

- Advise patient to take drug exactly as prescribed and not to stop abruptly because severe hypertension and withdrawal symptoms may occur.

- Instruct patient to consult prescriber if dry mouth or drowsiness becomes a problem during oral clonidine therapy. To minimize these effects, prescriber may suggest taking most of dosage at bedtime.
- Know that if a transdermal patch loosens during 7-day application period, tell patient to place adhesive overlay directly over patch to ensure adhesion.
- Tell patient to rotate transdermal sites.
- Instruct patient to remove patch and place a fresh one on another site if skin irritation, rash, or redness develops at patch site.
- Advise patient to fold used transdermal patch in half with adhesive sides together and discard it out of the reach of children.
- Instruct patient to swallow E.R. tablets whole and never chew, crush, or cut the tablets.
- Advise patient to avoid hazardous activities until drug's CNS effects are known. Caution patient that these effects are increased by concomitant use of alcohol, barbiturates, or other sedating drugs.
- Advise men that libido may decrease.
- Instruct patient to report chest pain, dizziness with position changes, excessive drowsiness, rash, urine retention, and vision changes. As needed, tell patient to rise slowly to avoid hypotensive effects.
- Inform patient who wears contact lenses that clonidine may cause dry eyes.

## clopidogrel bisulfate

**Plavix**

### **Class and Category**

*Pharmacologic class:* P2Y<sub>12</sub> platelet inhibitor

*Therapeutic class:* Platelet aggregation inhibitor

## Indications and Dosages

- *To reduce thrombotic events, such as MI and stroke, in patients with atherosclerosis documented by recent MI, peripheral artery disease, or stroke*
- *To reduce the rate of CVA and MI in patient with established peripheral arterial disease or a history of recent MI*

### TABLETS

**Adults.** 75 mg daily.

- *To reduce rate of CVA and MI in patients with non-ST-segment elevation acute coronary syndrome (unstable angina/non-ST-elevation myocardial infarction), including patients who are to be managed medically and those who are to be managed with coronary revascularization*

### TABLETS

**Adults.** *Loading dose:* 300 mg as a single dose.

*Maintenance:* 75 mg daily.

Route	Onset	Peak	Duration
P.O.	2 hr	3–7 days*	5 days

\* With repeated doses.

## Mechanism of Action

Binds to adenosine diphosphate (ADP) receptors on the surface of activated platelets. This action blocks ADP, which deactivates nearby glycoprotein IIb/IIIa receptors and prevents fibrinogen from attaching to receptors.

Without fibrinogen, platelets can't aggregate and form thrombi.

## Contraindications

Active pathological bleeding, including intracranial hemorrhage and peptic ulcer; hypersensitivity to clopidogrel or its components

## Interactions

### DRUGS

*aspirin*: Increased risk of bleeding

*CYP2C19 inhibitors, such as deslansoprazole, esomeprazole, lansoprazole, omeprazole, pantoprazole*: Decreased plasma clopidogrel level, decreased platelet inhibition

*NSAIDs, serotonin norepinehrine reuptake inhibitors (SNRIs), selective serotonin reuptake inhibitors (SSRIs)*: Increased risk of GI bleeding

*opioid agonists*: Delayed and reduced absorption of clopidogrel

*repaglinide and other CYP2C8 inhibitors*: Increased repaglinide and other CYP2C8 inhibitors exposure possibly increasing risk of adverse reactions, especially hypoglycemia

*warfarin*: Prolonged bleeding time, increased risk of bleeding

## Adverse Reactions

**CNS**: Confusion, depression, dizziness, **fatal intracranial bleeding**, fatigue, fever, hallucinations, headache

**CV:** Chest pain, edema, hypercholesterolemia, hypertension, **hypotension**, vasculitis

**EENT:** Altered or loss of taste; conjunctival, ocular, or retinal bleeding; epistaxis; rhinitis; stomatitis; taste disorders

**ENDO:** **Insulin autoimmune syndrome, severe hypoglycemia**

**GI:** Abdominal pain; **acute liver failure**; colitis; diarrhea; duodenal, gastric, or peptic ulcer; elevated liver enzymes; gastritis; **gastrointestinal and retroperitoneal hemorrhage**; indigestion; nausea; **noninfectious hepatitis, pancreatitis**

**GU:** Elevated serum creatinine level, **glomerulopathy**, UTI

**HEME:** **Acquired hemophilia A, agranulocytosis, aplastic anemia, neutropenia, pancytopenia, prolonged bleeding time, thrombocytopenic purpura, thrombotic thrombocytopenic purpura, unusual bleeding** or bruising

**MS:** Arthralgia, back pain, musculoskeletal bleeding, myalgia

**RESP:** Bronchitis, **bronchospasm**, cough, dyspnea, **eczema, eosinophilic pneumonia, interstitial pneumonitis, respiratory tract bleeding**, upper respiratory tract infection

**SKIN:** **Acute generalized exanthematous pustulosis**, bullous dermatitis, **erythema multiforme, exfoliative dermatitis**, lichen planus, pruritus, skin bleeding, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis, angioedema, drug reaction with eosinophilia and systemic symptoms (DRESS)**, flu-like

symptoms, serum sickness

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug can cause fetal harm.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.

### **LABOR & DELIVERY**

- Drug may cause maternal bleeding and hemorrhage if given during labor and delivery.
- Know that drug should be temporarily withheld for 5 to 7 days prior to labor, delivery, or use with neuraxial anesthesia, if possible.

### **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Avoid clopidogrel in patients who have a genetic variation in CYP2C19 or are receiving CYP2C19 inhibitors. Platelet inhibition may decline, increasing the risk of adverse cardiovascular effects after MI.
- Determine if patient has a history of hypersensitivity that may have included a hematologic reaction to any other thienopyridine drug, such as prasugrel or ticlopidine, because allergic cross-reactivity has been reported.
- Use clopidogrel cautiously in patients with severe hepatic or renal disease, risk of bleeding from surgery or trauma, or conditions that predispose to bleeding (such as peptic ulcer disease or thrombotic thrombocytopenic purpura).

- Expect to give aspirin with clopidogrel in patient with acute coronary syndrome.

**WARNING** Be aware that clopidogrel prolongs bleeding time; expect to stop it 5 days before elective surgery.

- Obtain blood cell count, as ordered, whenever signs and symptoms suggest a hematologic problem.
- Monitor patient who takes aspirin closely because risk of bleeding is increased.

## PATIENT TEACHING

- Discourage use of NSAIDs, including OTC preparations, during clopidogrel therapy because of potential for bleeding.
- Caution patient that bleeding may continue longer than usual. Instruct him to report unusual bleeding or bruising.
- Urge patient to inform all other healthcare providers, including dentists, that he takes clopidogrel before having surgery or other procedures or taking a new drug because he has an increased risk of bleeding.
- Advise patient to notify prescriber promptly if he experiences extreme skin paleness, fever, neurologic changes, purple skin patches, weakness, or yellowing of his skin or eyes.
- Instruct patient not to discontinue clopidogrel abruptly or without first consulting prescriber.

**WARNING** Warn patient that drug may cause low blood sugar levels. Review signs and symptoms of hypoglycemia and how to treat. Tell patient to notify prescriber if hypoglycemia occurs because it can cause persistent hypoglycemia, which could become severe.

# clozapine

# Clozaril, FazaClo, Versacloz

## Class and Category

*Pharmacologic class:* Atypical antipsychotic

*Therapeutic class:* Atypical antipsychotic

## Indications and Dosages

- *To treat severe schizophrenia unresponsive to standard drugs; to reduce risk of recurrent suicidal behavior in schizophrenia or schizoaffective disorders*

### ORALLY DISINTEGRATING TABLETS, ORAL SUSPENSION, TABLETS

**Adults.** *Initial:* 12.5 mg once or twice daily. Increased by 25 to 50 mg daily to 300 to 450 mg daily in divided doses by the end of 2 wk. Subsequently, dosage titration shouldn't exceed 100 mg twice per wk. *Maximum:* 900 mg daily in divided doses.

***DOSAGE ADJUSTMENT*** If patient is receiving a strong CYP1A2 inhibitor such as ciprofloxacin, enoxacin, or fluvoxamine concurrently, dosage decreased by two-thirds and then adjusted according to clinical response. If a patient is receiving a strong CYP1A2 inducer such as carbamazepine, phenytoin, rifampin, or St. John's wort concurrently, clozapine dosage may need to be increased if clinical response is ineffective. If patient has significant renal or hepatic impairment or is a CYP2D6 poor metabolizer, clozapine dosage may be decreased if patient develops significant adverse reactions.

---

**Route**

**Onset**

**Peak**

**Duration**

Route	Onset	Peak	Duration
P.O.	1–6 hr	Unknown	4–12 hr

## Mechanism of Action

May produce antipsychotic effects by interfering with dopamine binding to dopamine—especially D<sub>4</sub>—receptors in the limbic region of the brain and by antagonizing adrenergic, cholinergic, histaminic, and serotonergic receptors.

## Contraindications

Absolute neutrophil count (ANC) below 1,500/mm<sup>3</sup> for general population and at least 1,000/mm<sup>3</sup> for patients with Benign Ethnic Neutropenia, hypersensitivity to clozapine or its components

## Interactions

### DRUGS

*antidepressants (selected ones); carbamazepine; class IC antiarrhythmics such as encainide, flecainide, propafenone; phenothiazines;* Increased levels of these drugs with possible increased adverse reactions

*bupropion, cimetidine, ciprofloxacin, duloxetine, enoxacin, erythromycin, escitalopram, fluoxetine, fluvoxamine, oral contraceptives, paroxetine, quinidine, sertraline, terbinafine;* Possibly increased blood clozapine level and increased risk of adverse reactions

*carbamazepine, phenytoin, rifampin, St. John's wort:* Decreased blood clozapine level with decreased effectiveness

*chlorpromazine, class 1Aa antiarrhythmias such as quinidine or procainamide, class III antiarrhythmias such as amiodarone or sotalol, dolasetron, droperidol, erythromycin, gatifloxacin, halofantrine, iloperidone, levomethadyl, mesoridazine, mefloquine, methadone, moxifloxacin, pentamidine, pimozide, probucol, sparfloxacin, tacrolimus, thioridazine ziprasidone: Possible increased risk of prolonged QT interval*  
*CNS depressants: Increased CNS depression*

## **ACTIVITIES**

*alcohol use: Increased CNS depression*

*caffeine: Increased blood clozapine level*

*smoking: Decreased blood clozapine level*

## **Adverse Reactions**

**CNS:** Agitation, akinesia, anxiety, ataxia, cholinergic rebound adverse reactions postdiscontinuation, confusion, delirium, depression, dizziness, drowsiness, dystonia, EEG abnormality, fatigue, fever, headache, hyperkinesia, hypokinesia, insomnia, lethargy, myoclonic jerks, **neuroleptic malignant syndrome**, nightmares, obsessive-compulsive symptoms, paresthesia, possible cataplexy, restlessness, rigidity, sedation, **seizures**, sleep disturbance including **sleep apnea**, slurred speech, **status epilepticus**, syncope, tardive dyskinesia, tremor, vertigo, weakness

**CV:** **Atrial or ventricular fibrillation**, **bradycardia**, **cardiac arrest**, **cardiomyopathy**, chest pain, **deep vein thrombosis**, **ECG changes**, hypercholesterolemia, **hypertension**, hypertriglyceridemia, hypotension, leukocytoclastic vasculitis, **MI**, **mitral valve**

**incompetence, myocarditis**, orthostatic hypotension, palpitations, **QT-interval prolongation**, tachycardia, **torsades de pointes**, vasculitis, **ventricular tachycardia**

**EENT:** Blurred vision, dry mouth, increased nasal congestion, increased salivation, narrow-angle glaucoma, periorbital edema, pharyngitis, salivary gland swelling, tongue numbness or soreness

**ENDO:** **Ketoacidosis, pseudopheochromocytoma, severe hyperglycemia**

**GI:** Abdominal discomfort, **acute pancreatitis**, anorexia, cholestasis, colitis, constipation, diarrhea, dysphagia, elevated liver enzymes, heartburn, **hepatic cirrhosis or fibrosis, hepatitis, hepatotoxicity**, jaundice, **liver failure or injury**, nausea, vomiting

**GU:** Abnormal ejaculation including retrograde; acute interstitial nephritis; nocturnal enuresis; priapism; **renal failure**; urinary frequency, urgency, and incontinence; urine retention

**HEME:** **Agranulocytosis**; elevated hemoglobin, hematocrit and erythrocyte sedimentation rate; eosinophilia; **granulocytopenia; leukopenia; neutropenia (may become severe); thrombocytopenia**; thrombocytosis

**MS:** Back or leg pain, elevated creatine phosphokinase, muscle spasm or weakness, myalgia, myasthenic syndrome, **rhabdomyolysis**

**RESP:** **Aspiration**, dyspnea, lower respiratory tract infection, pleural effusion, pneumonia, **pulmonary embolism, respiratory arrest**

**SKIN:** **Erythema multiforme**, photosensitivity, pigmentation disorder, pruritus, rash, **Stevens-Johnson**

**syndrome**, urticaria

**Other:** **Angioedema**, **hypersensitivity reactions**, hyperuricemia, **hyponatremia**, **sepsis**, systemic lupus erythematosus, weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm. However, neonates exposed to antipsychotic drugs such as clozapine in utero are at risk for extrapyramidal and/or withdrawal symptoms following delivery.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Use clozapine cautiously in patients with cardiovascular, hepatic, or renal disease because they have increased risk of serious or fatal adverse reactions. Also use cautiously in patients with risk factors for a stroke because drug use may increase risk of cerebrovascular adverse events.
- Be aware that clozapine should not be given to elderly patients with dementia-related psychosis.
- Use cautiously in patients with a history of prolonged QT syndrome or who have existing conditions that might prolong the QT interval such as a recent MI, serious cardiac arrhythmia, or uncompensated heart failure. Drug should also be used cautiously in patients with cardiovascular disease or a family history of prolonged QT syndrome because clozapine therapy may increase the QT interval enough to cause life-threatening arrhythmias such as torsades de pointes, especially in patients who are

hypokalemic. Know that hypokalemia should be corrected, if present, before clozapine therapy begins and the serum potassium level monitored closely throughout therapy. If QT prolongation occurs, notify prescriber and expect drug to be discontinued if the QT interval exceeds 500 msec.

**WARNING** Know that, rarely, clozapine causes severe or life-threatening adverse reactions, such as agranulocytosis, cardiac or respiratory arrest, deep vein thrombosis, myocarditis (especially in first month), neuroleptic malignant syndrome, and severe hyperglycemia with ketoacidosis in nondiabetic patients. It also may cause seizures and tardive dyskinesia. Monitor patient closely. Know that these risks are often dose-related. Expect therapy to begin with a dose as low as 12.5 mg with titration done slowly and divided daily dosing used.

**WARNING** Check patient's baseline complete blood count (CBC), including differential before therapy and weekly for first 6 months, as ordered. Know that the baseline absolute neutrophil count (ANC) must be at least 1,500/ $\mu$ l for the general population; and must be at least 1,000/ $\mu$ l for patients with documented Benign Ethnic Neutropenia (BEN) before therapy can begin. If ANC remains equal to or greater than 1,500/ $\mu$ l during the first 6 months, expect to check the patient's ANC to check every 2 weeks for next 6 months, as ordered. If counts remain stable, expect to continue checking every 4 weeks thereafter. Also, know that laboratory monitoring may be reduced for hospice patients with an estimated life expectancy of 6 months or less. Be aware that because of the risk for severe neutropenia, clozapine is only available through a restricted program.

- Be aware that because of the risk of severe neutropenia, clozapine is available only through a restricted program called the Clozapine REMS Program. If patient develops mild neutropenia (1,000 to 1,499/ $\mu$ l),

treatment should be expected to continue but ANC monitoring should be increased to three times weekly until level reaches 1,500/ $\mu$ l. If patient develops moderate neutropenia (500 to 999/ $\mu$ l), expect treatment to be interrupted and daily monitoring of the patient's ANC done until the level reaches 1,000/ $\mu$ l, then three times a week monitoring until level reaches 1,500/ $\mu$ l. Expect therapy to be resumed once ANC reaches 1,000/ $\mu$ l. If patient develops severe neutropenia (less than 500/ $\mu$ l) expect drug to be discontinued, and daily monitoring of ANC until it reaches 1,000/ $\mu$ l, then three times weekly until it is normal. Be aware that clozapine therapy should not be restarted unless the benefits outweigh future risks and if restarted, the patient should resume treatment as a new patient receiving drug for the first time.

- Monitor temperature. Expect to withhold clozapine if patient develops a fever of 38.5°C (101.3°F) or higher and obtain an ANC level immediately as fever is often the first sign of neutropenic infection.
- Expect to check ANC weekly for at least 4 weeks after therapy ends or until ANC is 1,500/ $\mu$ l or more.
- Monitor patients, especially male patients and younger patients, for dystonia, particularly during the first few days of treatment. Be alert for complaints of neck spasms, which sometimes may progress to throat tightness, trouble swallowing or breathing, and tongue protrusion.
- Monitor patient for signs and symptoms of cardiomyopathy, mitral valve incompetence, or myocarditis such as chest pain, dyspnea, ECG changes, fever, flu-like symptoms, hypotension, palpitations, or tachycardia. If present, notify prescriber immediately and expect drug to be discontinued and a cardiac evaluation done promptly.
- Monitor patient's liver enzymes, as ordered. Report any signs of liver dysfunction such as anorexia, fatigue, jaundice, malaise, or nausea to prescriber. Expect clozapine to be discontinued if liver enzymes become elevated in combination with symptoms or patient develops hepatitis.

## **PATIENT TEACHING**

- Tell patient that he'll receive only a 1-week supply at a time.
- Instruct patient taking orally disintegrating tablets (Fazaclo) to leave tablet in blister pack until ready to take it. Tell him to peel foil back to remove tablet (rather than pushing tablet through foil) and then to immediately place tablet in mouth and let it dissolve before swallowing. Explain that no water is needed.
- Instruct patient prescribed oral suspension form to shake container for 10 seconds before every administration. The oral dosing syringe provided

with the product should be the only device used to measure dosage. Tell patient to firmly insert adapter into the neck of the bottle before the first use and keep it there. Instruct patient to first fill the syringe with air equivalent to the dose being withdrawn from the bottle. To withdraw the dose, he should insert the dosing syringe into the adapter and push air from syringe into the bottle. Then he should invert bottle and slowly pull back the plunger to the prescribed dose. After removing the syringe from the bottle adapter, the patient should be told to slowly squirt the suspension into his mouth. Then he should replace the cap over the adapter until next dose is due and rinse syringe well with warm water and dry.

- Inform patient that he'll need weekly blood tests. Review evidence of dyscrasias (fatigue, fever, sore throat, weakness); urge patient to report them to prescriber if they occur.
- Instruct patient to avoid hazardous activities until drug's CNS effects are known.
- Alert patient and family of increased risk for falls, especially if patient has other medical conditions or takes medication that may affect the nervous system.
- Tell patient to report any persistent, severe, or unusual adverse effects to prescriber immediately.
- Advise patient to rise slowly from lying or sitting position to minimize orthostatic hypotension.
- Warn patient that if he stops drug for more than 2 days, he will need to contact prescriber for instructions; dosage will need to be changed.
- Tell patient to consult prescriber before using alcohol or taking OTC drugs.
- Advise female patients of childbearing age to notify prescriber if pregnancy occurs or is suspected. Alert her that breastfeeding is not recommended while on clozapine therapy.

## coagulation factor Xa, inactivated-zhzo

**Andexxa**

---

## Class and Category

*Pharmacologic class:* Human coagulation factor Xa, recombinant

*Therapeutic class:* Factor Xa inhibitor antidote

## Indications and Dosages

- *To reverse life-threatening or uncontrolled bleeding induced by apixaban or rivaroxaban therapy*

### I.V. INFUSION, I.V. INJECTION

**Adults.** *For low dose (used if last dose of apixaban was 5 mg or less, rivaroxaban was 10 mg or less, and last dose of either drug was taken less than 8 hr or unknown):* 400 mg infused at 30 mg/min given as an I.V. bolus, followed by 4 mg/min for up to 120 min given as an I.V. infusion. *For high dose (used if last dose of apixaban was greater than 5 mg or unknown or rivaroxaban was greater than 10 mg or unknown and last dose of either drug was taken less than 8 hr or unknown):* 800 mg infused at 30 mg/min given as an I.V. bolus, followed by 8 mg/min for up to 120 min given as an I.V. infusion. If either drug was taken 8 hr or more, regardless of dosage, low dose regimen used.

Route	Onset	Peak	Duration
I.V.	2-5 min (bolus)	4 hr	2 hr (following infusion)

## Mechanism of Action

Binds and sequesters the factor Xa inhibitors apixaban and rivaroxaban, thereby exerting its procoagulant effect.

# Contraindications

Hypersensitivity to coagulation factor Xa, inactivated-zhzo or its components

# Interactions

## DRUGS

None reported

# Adverse Reactions

**CV:** **Thromboembolic events**

**EENT:** Altered sense of taste

**GU:** UTI

**RESP:** Cough, dyspnea, pneumonia

**SKIN:** Flushing, urticaria

**Other:** Anticoagulation factor Xa, inactivated-zhzo antibodies; feeling hot

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.

- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that the dosing of coagulation factor Xa, inactivated-zhzo is based on the specific drug that had been administered (apixaban or rivaroxaban), dose of the drug taken, and the time since the patient's last dose of the drug.
- Prepare I.V. bolus by reconstituting each 100-mg vial of coagulation factor Xa, inactivated-zhzo by slowly injecting 10 ml of sterile water for injection using a 20-gauge needle or higher and directing the solution onto the inside wall of the vial to minimize foaming. Gently swirl each vial until powder is completely dissolved. Do not shake, to avoid foaming. This takes about 3 to 5 minutes. Use a 60-ml syringe or larger with a 20-gauge needle to withdraw the reconstituted solution from each of the vials until the required dosing volume is achieved. Transfer the solution from the syringe into an empty polyolefin or polyvinyl chloride I.V. bag with a volume of 250 ml or less. Administer the bolus at a rate of 30 mg/min.
- Prepare I.V. infusion following the same procedure for I.V. bolus preparation. Use a 0.2- or 0.22-micron in-line polyethersulfone or equivalent low protein-binding filter. Within 2 minutes following the bolus dose, administer the continuous I.V. infusion for up to 120 minutes, as prescribed.
- Know that vials that have been reconstituted are stable at room temperature for up to 8 hours, or may be stored for up to 24 hours if refrigerated. Reconstituted solution in I.V. bags is stable at room temperature for up to 8 hours and may be stored for up to 16 hours if refrigerated.

**WARNING** Monitor patient closely for thrombosis, because patients treated with coagulation factor Xa, inactivated-zhzo have underlying disease states that predispose them to thromboembolic events that can occur up to 30 days after drug has been administered. Expect patient to resume anticoagulant therapy as soon as possible following use of coagulation factor Xa, inactivated-zhzo to reduce the risk of thrombosis.

## PATIENT TEACHING

- Inform patient that coagulation factor Xa, inactivated-zhzo is administered in two steps: first, as an intravenous bolus; then followed by a continuous intravenous infusion that may last up to 2 hours after the bolus has been given.

**WARNING** Inform patient that reversing the effects of the prescribed apixaban or rivaroxaban increases the risk of thromboembolic events for up to 30 days following the administration of coagulation factor Xa, inactivated-zhzo. Review the signs and symptoms of a blood clot that may occur in various areas of the body. Urge patient to seek immediate medical attention if a blood clot is suspected.

**codeine phosphate**

**codeine sulfate**

## **Class, Category, and Schedule**

*Pharmacologic class:* Opioid

*Therapeutic class:* Antitussive, opioid analgesic

*Controlled substance schedule:* II

## **Indications and Dosages**

- *To treat pain severe enough to require opioid treatment and for which alternative treatment options (e.g., nonopioid analgesics or opioid combination products) are inadequate or not tolerated*

## ORAL SOLUTION, TABLETS, I.M. OR SUBCUTANEOUS INJECTION

**Adults.** 15 to 60 mg (usual, 30 mg) every 4 to 6 hr, as needed. *Maximum:* 360 mg in 24 hours.

- *To treat cough from chemical or mechanical irritation of respiratory system*

## ORAL SOLUTION, TABLETS

**Adults.** 10 to 20 mg every 4 to 6 hr. *Maximum:* 120 mg daily.

Route	Onset	Peak	Duration
P.O.	30-45 min	1-2 hr	4 hr*
I.M.	10-30 min	30-60 min	4 hr*
SubQ	10-30 min	Unknown	4 hr*

\* For pain; 4 to 6 hr for cough.

## Mechanism of Action

May produce analgesia through partial metabolism to morphine. Drug binds with delta, kappa, and mu receptors in the spinal cord and with kappa<sub>3</sub> and mu<sub>1</sub> receptors higher in the CNS, decreasing intracellular cAMP, which inhibits adenylate cyclase activity and prevents release of pain neurotransmitters, such as dopamine and substance P, and altering perception of and emotional response to pain. Drug also suppresses cough by acting on opiate receptors in the cough center.

## Contraindications

Acute or severe bronchial asthma in an unmonitored setting or absence of resuscitative equipment, children under the age of 12 for all uses and adolescents under the age of 18 for use with cold and cough medications; gastrointestinal obstruction, including paralytic ileus; hypersensitivity to codeine, other opioids, or their components; significant respiratory depression; use of MAO inhibitors or within past 14 days; use for postoperative pain management in adolescents under the age of 18 who have undergone adenoidectomy and/or tonsillectomy

## Interactions

### DRUGS

*anticholinergics*: Increased risk of severe constipation and urinary retention

*antihypertensives, diuretics*: Potentiated hypotensive effects

*benzodiazepines, CNS depressants, muscle relaxants, other opioids, sedating antihistamines, tricyclic antidepressants*: Increased risk of severe respiratory depression and significant sedation and somnolence

*buprenorphine, butorphanol, nalbuphine, pentazocine*: Possibly reduce analgesic effect of codeine and/or precipitate withdrawal symptoms

*CYP2D6 inhibitors (such as bupropion, fluoxetine, paroxetine, quinidine)*: Possibly decreased effectiveness of codeine that may cause some patients to experience opioid withdrawal

*CYP2D6 inhibitor that is being discontinued*: Possibly increase or prolong adverse reactions and potentially fatal respiratory depression

*CYP3A4 inducers (such as carbamazepine, phenytoin, rifampin) or discontinuation of a CYP3A4 inhibitor (such as*

*azole antifungals, macrolide antibiotics, protease inhibitors*): Decreased plasma codeine concentration with possible decreased effectiveness, causing some patients to experience opioid withdrawal

*CYP3A4 inhibitors or discontinuation of a CYP3A4 inducer*: Increased plasma codeine concentration leading to increased or prolonged adverse reactions and potentially fatal respiratory depression

*diuretics*: Reduced effectiveness of diuretics

*MAO inhibitors such as linezolid, tranylcypromine*: Increased risk of unpredictable, severe, and sometimes fatal reactions

*muscle relaxants*: Possibly enhanced neuromuscular blocking action of skeletal muscle relaxants; increased severity of respiratory depression

*naloxone*: Antagonized codeine effect

*naltrexone*: Precipitated withdrawal symptoms in codeine-dependent patients

*serotonergic drugs such as 5-HTA3 receptor antagonists, cyclobenzaprine, I.V. methylene blue, linezolid, MAO inhibitors, metaxalone, mirtazapine, selective serotonin reuptake inhibitors (SSRIs), serotonin and norepinephrine reuptake inhibitors (SNRIs), tramadol, trazodone, tricyclic antidepressants, triptans*: Increased risk of serotonin syndrome

## **ACTIVITIES**

*alcohol use*: Additive CNS effects, including severe respiratory depression and significant sedation and somnolence

## **Adverse Reactions**

**CNS:** **Coma**, delirium, depression, disorientation, dizziness, drowsiness, euphoria, hallucinations, headache, lack of coordination, lethargy, light-headedness, mental and physical impairment, mood changes, restlessness, sedation, **seizures**, tremor

**CV:** **Bradycardia**, **heart block**, hypertension, orthostatic hypotension, palpitations, tachycardia

**EENT:** Altered taste, blurred vision, diplopia, dry mouth, **laryngeal edema**, **laryngospasm**, miosis

**ENDO:** **Adrenal insufficiency (rare)**

**GI:** Abdominal cramps and pain, anorexia, constipation, flatulence, gastroesophageal reflux, ileus, indigestion, nausea, vomiting

**GU:** Decreased libido, difficult ejaculation, dysuria, erectile dysfunction, impotence, infertility with prolonged use, lack of menstruation, oliguria, ureteral spasm, urinary incontinence, urine retention

**MS:** Muscle rigidity

**RESP:** **Apnea**, **bronchoconstriction**, **bronchospasm**, **depressed cough reflex**, **respiratory depression**, **sleep-related breathing disorders (sleep apnea, sleep-related hypoxemia)**

**SKIN:** Diaphoresis, flushing, pallor, pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, physical and psychological dependence

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug can cause fetal harm, but drug does cross the placental barrier. However, prolonged use of drug during pregnancy may cause physical dependence in the neonate resulting in Neonatal Opioid Withdrawal Syndrome shortly after birth.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.

## **LABOR & DELIVERY**

- Infants exposed to codeine during labor should be assessed for excess sedation and respiratory depression.

## **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, mother should monitor breastfed infant for breathing difficulties and drowsiness as well as withdrawal symptoms when breastfeeding ceases.

## **Nursing Considerations**

- Evaluate patient's risk for abuse and addiction prior to the start of codeine therapy as excessive use of the drug may lead to abuse, addiction, misuse, overdose, and possibly death. Be prepared to monitor patient's intake throughout therapy. Because of the potential risks associated with codeine therapy, be aware that the FDA now requires a Risk Evaluation and Mitigation Strategy (REMS) for codeine use to educate the patient.

**WARNING** Know that codeine should not be given to children under the age of 12 for any reason and for adolescents under the age of 18 when used in cold or cough preparations, as well as following adenoidectomy and/or tonsillectomy. Also know that codeine should not be given to children age 12 to 18 if they have other risk factors that may increase their sensitivity to the respiratory depressant effects of codeine. Risk factors

include conditions associated with hypoventilation such as concomitant use of other medications that cause respiratory depression or the presence of neuromuscular disease, obesity, obstructive sleep apnea, or severe pulmonary disease. In addition, codeine should not be given to patients who are known ultrarapid metabolizers of codeine, including mothers who are breastfeeding, as breast-fed infants have died when exposed to high levels of morphine (codeine converts to morphine) in breast milk. Monitor any patient receiving codeine closely, especially the patient who has never received a narcotic like codeine or morphine, for signs of overdose such as confusion, extreme sleepiness, or shallow breathing because patient may not know he is an ultrarapid metabolizer. Some patients are ultrarapid metabolizers because of a CYP2D6 polymorphism. How prevalent this phenotype is varies widely. It is estimated that 0.5% to 1% Chinese, Hispanics, and Japanese; 1% to 10% Caucasians; 3% African Americans; and 16% to 28% of Arabs, Ethiopians, and North Africans may carry the CYP2D6 genotype.

- Evaluate patient for therapeutic response, including decreased cough, facial grimacing, and pain.

**WARNING** Be aware that opioid therapy like codeine should only be used concomitantly with benzodiazepine therapy in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of the opioid to be limited. Monitor patient closely for signs and symptoms of decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

- Take safety precautions, if needed.
- Monitor respiratory depth, effort, and rate, because codeine can cause respiratory depression that could become life-threatening. Notify prescriber immediately if respiratory rate drops below 10 breaths/min.
- Assess urine output to detect retention.
- Repeated injection in same site may cause tissue irritation, pain, and induration.
- Rotate sites for subcutaneous delivery.

**WARNING** Know that many drugs may interact with opioids like codeine to cause serotonin syndrome. Monitor patient closely for signs and symptoms such as agitation, diaphoresis, diarrhea, fever, hallucinations, labile blood pressure, muscle twitching or stiffness, nausea, shakiness, shivering, tachycardia, trouble with coordination, or vomiting. Notify prescriber at once because serotonin syndrome may be life-threatening. Be prepared to discontinue drug, if possible, and provide supportive care.

- Monitor patient for adrenal insufficiency. Although rare, it can be life-threatening. Monitor patient for anorexia, dizziness, fatigue, hypotension, nausea, vomiting, or weakness. Notify prescriber if adrenal insufficiency is suspected and expect diagnostic testing to be done to determine if present. If diagnosis is confirmed, expect to administer corticosteroids and wean patient off codeine, if possible.
- Be aware that drug therapy should not be stopped abruptly in a physically dependent patient.
- Know that chronic maternal use of codeine during pregnancy can result in neonatal opioid withdrawal syndrome (NOWS), which may be life-threatening, if not recognized and treated appropriately. NOWS occurs when a newborn was exposed to opioid drugs like codeine for a prolonged period while in utero.

## **PATIENT TEACHING**

- Instruct patient to take codeine exactly as prescribed and not to adjust dose or frequency without consulting prescriber, because misuse increases risk of addiction.
- Suggest that patient take drug with food to minimize nausea.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Caution patient to get up slowly from a sitting or lying position.
- Urge patient to consume plenty of fluids and high-fiber foods, if not contraindicated, to prevent constipation.

**WARNING** Warn patient not to consume alcohol or take a benzodiazepine during codeine therapy without prescriber knowledge, as severe respiratory depression can occur and may lead to death.

**WARNING** Inform patient about potentially fatal additive effects of combining codeine with a benzodiazepine. Instruct patient to inform all prescribers of codeine use.

- Advise patient to report difficulty breathing or shortness of breath.
- Urge breastfeeding women to notify prescriber before taking codeine because drug appears in breast milk and could lead to overdose in infant.
- Inform patient that long-term use of opioids like codeine may decrease sex hormone levels, causing decreased libido, erectile dysfunction, impotence, infertility, or lack of menstruation. Encourage patient to report any such symptoms.
- Caution pregnant patient not to increase dosage or take codeine for a prolonged period, because infant may experience withdrawal when born.
- Warn patient to keep codeine out of the reach of children to prevent accidental ingestion that could be life-threatening.
- Instruct patient to tell all prescribers of codeine use and not to take any over-the-counter medication, including herbal medicines, without prescriber knowledge.

# colchicine

**Colcrys, Gloperba, Mitigare**

## Class and Category

*Pharmacologic class:* Colchicum alkaloid derivative

*Therapeutic class:* Antigout

## Indications and Dosages

➤ *To prevent gouty arthritis attacks*

### **CAPSULES, ORAL SOLUTION, TABLETS**

**Adults and adolescents age 16 and over.** 0.6 mg once or twice daily. *Maximum:* 1.2 mg daily.

➤ *To treat acute gouty arthritis*

### **TABLETS (COLCRYS)**

**Adults.** *Initial:* 1.2 mg at first sign of flare; then 0.6 mg 1 hr later. *Maximum:* 1.8 mg over a 1-hr period.

***DOSAGE ADJUSTMENT (COLCRYS)*** For elderly patients, maximum dosage reduced to 2 mg/24 hr. If treatment of a gout flare occurs during prophylactic treatment, dosage shouldn't exceed 1.2 mg at the first sign of flare, followed by 0.6 mg 1 hr later, and then prophylactic dose resumed 12 hr later. For patient taking strong CYP3A4 inhibitor (atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin), moderate CYP3A4 inhibitor (amprenavir, aprepitant, diltiazem, erythromycin, fluconazole, fosamprenavir,

grapefruit juice, verapamil), or P-gp inhibitor (cyclosporine, ranolazine), dosage usually halved and not repeated for 3 days.

For patient with moderate to severe renal impairment, dosage adjusted on individual basis. For patient with severe hepatic impairment receiving colchicine prophylactically, dosage decreased on individual basis. For patient with severe hepatic impairment receiving colchicine treatment for acute gout flare but not prophylaxis, dosage not adjusted but treatment course shouldn't be repeated more than once every 2 weeks.

➤ *To treat familial Mediterranean fever (FMF)*

## **TABLETS (COLCRYS)**

**Adults and adolescents ages 12 and over.** 1.2 mg to 2.4 mg daily, with daily total divided into two doses, if desired.

**Children ages 6 to 12.** 0.9 to 1.8 mg daily, with daily total divided into two doses, if desired.

**Children ages 4 to 6.** 0.3 to 1.8 mg daily, with daily total divided into two doses, if desired.

***DOSAGE ADJUSTMENT (COLCRYS)*** For adults needing control of FMF, dosage increased in increments of 0.3 mg daily to a maximum of 2.4 mg daily.

For adults with intolerable adverse effects, dosage decreased in increments of 0.3 mg daily to tolerable level.

For patients taking strong CYP3A4 inhibitor (atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin), moderate CYP3A4 inhibitor (amprenavir, aprepitant, diltiazem, erythromycin, fluconazole, fosamprenavir, grapefruit juice, verapamil), or P-gp inhibitor (cyclosporine, ranolazine), dosage usually halved and not repeated for 3 days.

For patient with moderate to severe renal impairment or severe hepatic impairment, dosage adjusted on individual

basis.

Route	Onset	Peak	Duration
P.O.	In 12 hr	In 24–48 hr	Unknown

## Mechanism of Action

In gouty arthritis, leukocytes phagocytose urate crystals in affected joints, a process that releases chemotactic factors, degradation enzymes, and other inflammatory substances. Colchicine helps stop this process, probably by disrupting microtubules in leukocytes. Normally, microtubules contribute to cell structure and movement. When colchicine binds to tubulin (protein from which microtubules are made), the microtubule falls apart, as shown. This process disrupts cell function and prevents leukocytes from invading joints and causing inflammation.

## Contraindications

Both hepatic and renal impairment present; concurrent use with strong CYP3A4 inhibitors or P-glycoprotein inhibitors in patients with hepatic or renal impairment; hypersensitivity to colchicine or its components

## Interactions

### DRUGS

*clarithromycin, cyclosporin, ranolazine*: Significant increase in colchicine plasma levels with possible fatal

colchicine toxicity

*digoxin; HMG-CoA reductase inhibitors, such as atorvastatin, fluvastatin, lovastatin, pravastatin, simvastatin; other lipid-lowering drugs, such as fibrates, gemfibrozil:* Increased risk of myopathy and rhabdomyolysis

*diltiazem, verapamil:* Significant increase in colchicine plasma concentration with increased risk of colchicine toxicity; neuromuscular toxicity

*moderate CYP3A4 inhibitors, such as amprenavir, aprepitant, erythromycin, fluconazole, fosamprenavir:* Increased risk of colchicine toxicity

*strong CYP3A4 inhibitors, such as atazanavir, darunavir/ritonavir, indinavir, itraconazole, ketoconazole, lopinavir/ritonavir, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, tipranavir/ritonavir:* Significant increase in colchicine plasma levels with high risk of toxicity

## **ACTIVITIES**

*alcohol use:* Increased risk of adverse GI effects

## **FOOD**

*grapefruit juice:* Increased risk of colchicine toxicity

## **Adverse Reactions**

**CNS:** Peripheral neuropathy

**GI:** Abdominal pain, anorexia, diarrhea, nausea, vomiting

**HEME:** Agranulocytosis, aplastic anemia, thrombocytopenia

**MS:** Myopathy

**SKIN:** Alopecia, rash

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug can cause fetal harm but it does cross the placental barrier.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.

### **LACTATION**

- Drug is present in breast milk and may affect gastrointestinal cell renewal and permeability in the breastfed infant.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, mother should monitor infant for adverse reactions, especially gastrointestinal adverse effects.

## **Nursing Considerations**

- Know that debilitated or elderly patients and those with a history of cardiac disease or impaired hepatic or renal function are at increased risk for cumulative toxicity.
- Be aware that capsule and oral solution forms are only used to prevent gout flares, not to treat them.
- Expect to monitor CBC and platelet and reticulocyte counts at baseline and every 3 months after therapy starts.
- Notify prescriber immediately and expect to stop colchicine if patient develops evidence of toxicity, such as abdominal pain, diarrhea, nausea, or vomiting.

### **PATIENT TEACHING**

- Instruct patient to have blood tests every 3 months, as ordered, during therapy.
- Explain that gouty arthritis pain and swelling typically subside in 24 to 48 hours after therapy begins.
- Advise patient to notify prescriber immediately if abdominal pain, diarrhea, nausea, or vomiting occurs.
- Tell patient to inform all prescribers of colchicine therapy, especially if patient has kidney or liver dysfunction because of potential drug interactions.

## colesevelam hydrochloride

**Welchol**

### Class and Category

*Pharmacologic class:* Bile acid sequestrant

*Therapeutic class:* Antilipemic, hypoglycemic

### Indications and Dosages

- *As adjunct to diet and exercise to improve glycemic control in type 2 diabetes mellitus*

### CHEWABLE BARS, ORAL SUSPENSION, TABLETS

**Adults.** 3.75 g once daily or 1.875 g (tablet only) twice daily with a meal and a beverage.

- *As adjunct to diet and exercise to reduce elevated LDL cholesterol levels in patients with primary hypercholesterolemia as monotherapy or in combination with an HMG CoA reductase inhibitor*

## **CHEWABLE BARS, ORAL SUSPENSION, TABLETS**

**Adults and children age 10 to 17:** 3.75 g once daily or 1.875 g (tablet only) twice daily with a meal and a beverage.

## **Mechanism of Action**

Binds with bile acids in intestine, preventing their absorption and forming an insoluble complex that's excreted in feces. This action decreases amount of bile acids returning through enterohepatic circulation to the liver. As a result, the liver must convert more cholesterol to bile acids, which increases liver's demand for cholesterol. This, in turn, causes increase in production and activity of the hepatic enzyme hydroxymethyl-glutaryl-coenzyme A (HMG-CoA) reductase, which is needed for cholesterol production. However, synthesis of cholesterol in the liver typically can't match the amount needed to synthesize bile acids. Because cholesterol levels can't be sustained, LDLs, lipoproteins composed mostly of cholesterol, are increasingly removed from the blood, thereby decreasing the LDL level in the blood.

How glycemic control is improved in patients with type 2 diabetes mellitus is unknown.

## **Contraindications**

History of bowel obstruction or pancreatitis induced by hypertriglyceridemia, hypersensitivity to colesevelam or its components, serum triglyceride level greater than 500 mg/dl

## **Interactions**

## DRUGS

*cyclosporine, drugs with narrow therapeutic index, fat-soluble vitamins, glimepiride, glipizide, glyburide, olmesartan, oral contraceptives containing ethinyl estradiol and norethindrone, thyroid hormone replacement:* Possibly altered effectiveness of these drugs

*metformin E.R.:* Increased blood metformin level, increasing risk of hypoglycemia

*phenytoin:* Decreased plasma phenytoin levels increasing risk of seizures

*warfarin:* Reduced INR, increasing risk of clotting

## Adverse Reactions

**CNS:** Asthenia

**CV:** Hypertension, hypertriglyceridemia

**EENT:** Oral blistering, pharyngitis, rhinitis

**ENDO:** Hypertriglyceridemia, **hypoglycemia**

**GI:** Abdominal distention or pain, bowel or esophageal obstruction, constipation, dyspepsia, dysphagia, elevated liver enzymes, fecal impaction, indigestion, nausea, **pancreatitis**, worsening of hemorrhoids

**MS:** Myalgia

**SKIN:** Rash

**Other:** Fat-soluble vitamin deficiencies, flu-like syndrome

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm. However drug is not absorbed systemically and is not expected to result in fetal exposure.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk but is thought not to be since it is not absorbed systemically.
- Patient should check with prescriber before breastfeeding.

## **REPRODUCTION**

- Females using oral contraceptives should take the contraceptive at least 4 hours before taking drug.

## **Nursing Considerations**

- Know that colesevelam shouldn't be given to patients with gastroparesis or other GI motility disorders or to patients who had major GI tract surgery and are at risk for bowel obstruction from constipating effects.
- Use cautiously in patients with dysphagia or esophageal obstruction because size of tablet can cause dysphagia or esophageal obstruction.
- Use colesevelam cautiously in patients whose total triglycerides exceed 300 mg/dl; bile acid sequestrants can increase it.
- Evaluate patient's lipid levels before starting therapy for primary hyperlipidemia, again in 4 to 6 weeks, and then periodically, as ordered, during therapy. Expect drug to be discontinued if patient develops hypertriglyceridemia-induced pancreatitis or triglyceride level exceeds 500 mg/dl.
- Monitor diabetic patient's blood glucose level regularly, as ordered, to assess effectiveness of colesevelam therapy.
- Mix one packet of oral suspension with 4 to 8 ounces of water, fruit juice, or diet soft drinks. Stir well and have patient drink immediately.
- Know that when giving colesevelam with a drug that has a narrow therapeutic index, expect to give that drug at least 4 hours before

colesevelam to prevent reduced effectiveness.

- Administer colesevelam separately from other oral drugs because colesevelam may decrease or delay absorption of other drugs.
- Make sure that patient drinks enough fluid when taking drug.

**WARNING** Monitor patients with preexisting constipation, who are at increased risk for developing fecal impaction.

- Monitor frequency of bowel movements and consistency of stools in patients with coronary artery disease or hemorrhoids because constipation may aggravate these conditions.

## PATIENT TEACHING

- Instruct patient to take drug with meals and drink plenty of liquids when taking it.
- Tell patient to protect tablets from moisture.

**WARNING** Alert patient or caregiver prescribed oral suspension form that it contains phenylalanine and should not be taken by anyone who has a PKU diagnosis. If PKU is present, instruct patient not to take oral suspension and notify prescriber to get a different form of the drug.

- Instruct patient prescribed the oral suspension form to mix 1 packet with 8 ounces of diet soft drinks, fruit juice, or water; stir well; and then drink immediately. Caution patient never to ingest the contents of the packet dry. Tell patient to take the drug, regardless of form, with a meal.
- Caution patient against changing prescribed dosage or stopping colesevelam abruptly because serum lipid level may increase significantly.
- Remind patient that drug therapy doesn't reduce the need for dietary changes.
- Urge patient to keep regularly scheduled appointments for follow-up blood tests.

- Instruct patient to take colestevlam separately from other drugs, as it may decrease or delay absorption of other drugs.
- Tell patient to promptly seek medical attention and stop taking colestevlam if severe abdominal pain with or without nausea and vomiting occurs or severe constipation.
- Advise patient to take oral contraceptives and vitamins at least 4 hours before taking colestevlam.

## colestipol hydrochloride

### Colestid

## Class and Category

*Pharmacologic class:* Bile acid sequestrant

*Therapeutic class:* Antihyperlipidemic

## Indications and Dosages

- *As adjunct to diet and exercise to reduce elevated serum total and LDL-C in patients with primary hypercholesterolemia*

### GRANULES

**Adults.** *Initial:* 5 g once or twice daily. Then, increased, as needed, by 5 g per day at 1 to 2 month intervals. *Maximum:* 30 g daily.

### TABLETS

**Adults.**

*Initial:* 2 g once daily or in divided doses twice daily, increased every 1 to 2 months in 2-g increments once or twice daily. *Maximum:* 16 g daily.

## **Mechanism of Action**

Combines with bile acids in the intestine, preventing their absorption and forming an insoluble complex that's excreted in feces. Loss of bile acids increases hepatic production of cholesterol to form new bile acids and increases oxidation of cholesterol to bile acids. Depletion of cholesterol increases hepatic LDL receptor activity, which removes LDLs from the blood.

## **Contraindications**

Complete biliary obstruction, hypersensitivity to colestipol or its components

## **Interactions**

### **DRUGS**

*digoxin, hydrocortisone, oral phosphate supplements:* Possible binding of these drugs decreasing their effectiveness

*furosemide, gemfibrozil, penicillin G, propranolol, tetracycline, thiazide diuretics:* Decreased absorption of these drugs

*mycophenolic acid:* Possibly reduced effectiveness of mycophenolic acid

*oral drugs:* Possibly decreased absorption of oral drugs

*vancomycin (oral):* Possibly marked decrease in vancomycin antibacterial action

*vitamins (fat-soluble)*: Possibly interference with vitamin absorption

## **Adverse Reactions**

**CNS:** Headache

**GI:** Abdominal distention and pain, constipation, diarrhea, eructation, esophageal reaction, fecal impaction, heartburn, nausea, vomiting

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug can cause fetal harm. However drug is not absorbed systemically and is not expected to result in fetal exposure.
- Be aware that drug interferes with absorption of fat-soluble vitamins, which may make regular prenatal supplementation inadequate.
- Drug should be used with caution only if benefit to mother outweighs potential risk to fetus.

### **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- Be aware that the possibility of a lack of proper vitamin absorption may affect the breastfed infant.

## **Nursing Considerations**

- Mix colestipol granules with at least 90 ml of fluid before giving it to prevent accidental inhalation or esophageal distress.

- Give colestipol on a separate schedule from other oral drugs when possible because it may interact with various drugs.
- Make sure patient has adequate fluid intake, and obtain an order for a stool softener or laxative to prevent constipation. To prevent impaction, expect to decrease dosage or discontinue drug if constipation occurs or worsens.
- Expect to discontinue drug if no response occurs after 3 months.
- Monitor patient's serum cholesterol level as appropriate, usually at baseline, 4 to 6 weeks after starting therapy, and then every 3 months. Expect to reduce monitoring frequency to every 4 months if response is adequate.
- Be aware that HDL and serum triglyceride levels may increase or remain unchanged during colestipol therapy.
- Keep in mind that adverse GI reactions are more common in patients over age 60.

## **PATIENT TEACHING**

- Advise patient to mix granules thoroughly in at least 90 ml of fluid so they're completely wet before drinking.
- Remind patient that colestipol doesn't reduce the importance of dietary changes.
- Caution patient not to decrease or increase prescribed dosage or to stop taking drug suddenly. Explain that stopping drug abruptly may significantly increase serum lipid levels.
- Instruct patient to keep appointments for follow-up blood tests.
- Teach patient how to prevent constipation, and advise him to contact prescriber if constipation occurs or worsens.

**conivaptan hydrochloride**

**Vaprisol**

# Class and Category

*Pharmacologic class:* Arginine vasopressin antagonist

*Therapeutic class:* Aquaretic (sodium/water stabilizer)

## Indications and Dosages

- *To treat euvolemic and hypervolemic hyponatremia in hospitalized patients*

### I.V. INFUSION

**Adults.** *Loading dose:* 20 mg over 30 minutes followed by 20 mg as a continuous infusion over 24 hours. Additional 20 to 40 mg daily given by continuous infusion for 1 to 3 days. *Maximum:* 40 mg daily with total duration of therapy, including loading dose, not to exceed 4 days.

***DOSAGE ADJUSTMENT*** For patient with moderate hepatic impairment, loading dose decreased to 10 mg over 30 minutes followed by a decrease in daily dose to 10 mg/day as a continuous infusion for 2 to 4 days. If serum sodium level does not rise, dosage may be titrated up to 20 mg/day.

Route	Onset	Peak	Duration
I.V.	Unknown	24 hr	Unknown

## Mechanism of Action

Binds with arginine vasopressin V2 receptor sites in collecting ducts of kidneys. By doing so, drug blocks action of arginine vasopressin on V2 receptor, decreases water resorption in collecting ducts, increases excretion of free water (urine output), and increases serum sodium

concentration, thus correcting water and sodium imbalance.

## Incompatibilities

Don't mix with lactated Ringer's solution, normal saline solution, or other drugs.

## Contraindications

Anuria; hypersensitivity to conivaptan or its components or to corn or corn products; patients with hypovolemic hyponatremia; use with potent CYP3A4 inhibitors such as clarithromycin, indinavir, itraconazole, ketoconazole, and ritonavir

## Interactions

### DRUGS

*clarithromycin, indinavir, itraconazole, ketoconazole, ritonavir, and other strong CYP3A inhibitors:* Increased blood conivaptan level

*CYP3A substrates:* Increased exposure of these drugs

*digoxin:* Possibly increased digoxin level and risk of digoxin toxicity

*drugs metabolized by CYP3A, such as HMG-CoA reductase inhibitors; CYP3A substrates:* Possibly increased risk of rhabdomyolysis

## Adverse Reactions

**CNS:** Confusion, fever, headache, insomnia

**CV:** Atrial fibrillation, hypertension, hypotension, orthostatic hypotension, peripheral edema

**EENT:** Dry mouth, oral candidiasis, pharyngeal pain

**ENDO:** Hyperglycemia, hypoglycemia

**GI:** Constipation, diarrhea, nausea, thirst, vomiting

**GU:** Hematuria, pollakiuria, polyuria, UTI

**HEME:** Anemia

**RESP:** Pneumonia

**SKIN:** Erythema, pruritus

**Other:** Dehydration, hypokalemia, hypomagnesemia, hyponatremia, infusion-site reactions (erythema, pain, phlebitis, swelling)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding should not be undertaken during drug therapy because of the potential for serious adverse reaction in the breastfed infant.

## Nursing Considerations

- Know that conivaptan shouldn't be used to treat patients with heart failure nor is it recommended in patients with severe renal impairment

because of a high incidence of infusion-site phlebitis, which can reduce potential vascular access sites.

- Use cautiously in patients with hepatic or mild to moderate renal dysfunction because levels remain elevated longer in these patients.
- Give drug only through large veins, and change infusion site every 24 hours. Drug may cause serious infusion-site reactions even when diluted and infused correctly. Inspect site regularly; change immediately if reactions occur.
- Dilute 20-mg (4-ml) loading dose with 100 ml of 5% dextrose injection before administration. Gently invert bag several times to mix thoroughly. Use mixture within 24 hours, infusing over 30 minutes.
- Dilute 20-mg (4-ml) or 40-mg (8-ml) continuous infusion dose with 250 ml of D<sub>5</sub>W before use. Gently invert the bag several times to mix thoroughly. Infuse immediately over 24 hours. If infusion is interrupted for any reason, discard any remaining solution 24 hours after mixing.
- Monitor neurologic status and serum sodium level closely during therapy because rapid increase in serum sodium level (more than 12 mEq/L/24 hr) may result in serious neurologic impairment. If serum sodium level rises faster than expected, stop infusion temporarily and notify prescriber. If it keeps rising, expect conivaptan to be discontinued. If hyponatremia persists or recurs and patient has no neurologic abnormalities, drug may be resumed at a reduced rate.
- Monitor vital signs, and assess patient regularly for hypovolemia. If patient develops hypotension or hypovolemia while receiving conivaptan, stop infusion, notify prescriber, and provide supportive care, as prescribed. After hypotension and hypovolemia have been corrected, drug may be resumed at a reduced rate.
- Store ampules in cardboard container, protected from light, until ready for use.

## **PATIENT TEACHING**

- Instruct patient to report any infusion-site discomfort immediately.
  - Tell patient that frequent laboratory tests will be performed to monitor his serum sodium level and volume status.
  - Advise female patient of childbearing age not to breastfeed during conivaptan therapy.
-

# cortisone acetate

## **Cortisone Acetate-ICN (CAN), Cortone (CAN), Cortone Acetate**

### **Class and Category**

*Pharmacologic class:* Glucocorticoid

*Therapeutic class:* Anti-inflammatory, corticosteroid replacement, immuno-suppressant

### **Indications and Dosages**

- *To treat allergic and inflammatory disorders, collagen disorders, congenital adrenal hyperplasia, dermatologic disorders, edema (from nephrotic syndrome or systemic lupus erythematosus), GI disorders, hematologic disorders, multiple sclerosis (acute exacerbations), neoplastic diseases, primary or secondary adrenocortical insufficiency, respiratory disorders, rheumatic disorders, trichinosis with myocardial or neurologic involvement, and tuberculous meningitis*

### **TABLETS**

**Adults and adolescents.** *Initial:* 25 to 300 mg once daily or equally divided and given twice. *Maintenance:* Dosage adjusted based on patient response.

**Children.** 2.5 to 10 mg/kg daily divided into equal doses and given every 6 to 8 hr. For adrenocortical insufficiency,

0.5 to 0.75 mg/kg/daily divided into equal doses and given every 8 hr.

## I.M. INJECTION

**Adults and adolescents.** *Initial:* 25 to 300 mg daily.

*Maintenance:* Dosage adjusted based on patient response.

**Children.** Highly individualized. For adrenocortical insufficiency, 0.25 to 0.35 mg/kg once daily.

Route	Onset	Peak	Duration
P.O.	Rapid	2 hr	1.25–1.5 days
I.M.	Slow	20–48 hr	1.25–1.5 days

## Mechanism of Action

Binds to intracellular glucocorticoid receptors and suppresses inflammatory and immune responses by:

- inhibiting neutrophil and monocyte accumulation at the inflammation site and suppressing their phagocytic and bactericidal activity
- stabilizing lysosomal membranes
- suppressing the antigen response of macrophages and helper T cells
- inhibiting synthesis of cellular mediators of inflammatory response, such as cytokines, interleukins, and prostaglandins

## Contraindications

Hypersensitivity to cortisone or its components, idiopathic thrombocytopenic purpura (parenteral form), live-virus vaccine administration, systemic fungal infection

## Interactions

## DRUGS

*ephedrine, phenobarbital, phenytoin, rifampin*: Decreased blood levels of cortisone

*oral anticoagulants*: Possibly obstructed anticoagulant effects

*potassium-wasting diuretics*: Possibly hypokalemia

## Adverse Reactions

**CNS:** Ataxia, behavior changes, depression, dizziness, euphoria, fatigue, headache, **increased intracranial pressure with papilledema**, insomnia, lassitude, malaise, mood swings, paresthesia, **seizures**, steroid psychosis, syncope, vertigo

**CV:** **Arrhythmias**, **fat embolism**, **heart failure**, hypertension, **hypotension**, thrombophlebitis

**EENT:** Exophthalmos, glaucoma, increased intraocular pressure, nystagmus, posterior subcapsular cataracts

**ENDO:** **Adrenal insufficiency during**, Cushing's syndrome, diabetes mellitus, growth suppression in children, hyperglycemia, negative nitrogen balance from protein catabolism

**GI:** Abdominal distention, hiccups, increased appetite, nausea, **pancreatitis**, peptic ulcer, ulcerative esophagitis, vomiting

**GU:** Glycosuria, menstrual irregularities, perineal burning or tingling

**HEME:** Leukocytosis

**MS:** Arthralgia; aseptic necrosis of femoral and humeral heads; compression fractures; muscle atrophy, twitching,

and weakness; myalgia; osteoporosis; spontaneous fractures; steroid myopathy; tendon rupture

**SKIN:** Acne; diaphoresis; ecchymosis; erythema; hirsutism; hyperpigmentation; hypopigmentation; necrotizing vasculitis; petechiae; purpura; rash; scarring; sterile abscesses; striae; subcutaneous fat atrophy; thin, fragile skin; urticaria

**Other:** Anaphylaxis, hypocalcemia, hypo-kalemia, hypokalemic alkalosis, impaired wound healing, masking of infection, metabolic alkalosis, suppressed skin test reaction, weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.
- Monitor infant for hypoadrenalism if mother has received large doses of cortisone during pregnancy,

### LACTATION

- Drug is present in breast milk.
- Breastfeeding should not be undertaken with drug therapy because of potential serious adverse reactions in breastfed infant.

## Nursing Considerations

- Use cortisone cautiously in patients with ocular herpes simplex because corneal perforation may occur.

- Expect prescriber to order baseline ophthalmologic examination before therapy starts because prolonged use of cortisone may result in glaucoma, increased intraocular pressure, and damage to optic nerve.
- Assess patient for signs and symptoms of infection before giving cortisone because drug may mask them. Be aware that new infections may develop during therapy because of risk of immunosuppression. If a new infection develops, expect to administer appropriate antibiotics.
- Obtain serum electrolyte levels before therapy, as ordered, and monitor results often during therapy to detect electrolyte imbalances. Increased calcium excretion, potassium depletion, and sodium and water retention may occur with large doses of cortisone. Anticipate the need for calcium and potassium supplementation and sodium restriction, if indicated.
- Keep in mind that prescriber will order lowest effective dose.
- Expect patient to receive concurrent antacid or antihistamine therapy to prevent peptic ulcer from cortisone.

**WARNING** Be aware that live-virus vaccines shouldn't be given during cortisone therapy because patient may become immunosuppressed and develop the viral infection.

**WARNING** Assess for adrenal suppression or insufficiency (fatigue, hypotension, lassitude, nausea, vomiting, and weakness) in patient exposed to stress or receiving prolonged cortisone therapy. Notify prescriber immediately if patient has evidence of this life-threatening adverse reaction.

- Watch for signs and symptoms of steroid psychosis (confusion, delirium, euphoria, insomnia, mood swings, personality changes, severe depression), which may develop 15 to 30 days after starting drug. Be prepared to stop drug if such signs occur. If stopping isn't possible, expect to administer a psychotropic drug.
- Watch for cushingoid signs, such as acne, buffalo hump, central obesity, ecchymosis, moon face, striae, and weight gain. Notify prescriber at once if they occur.
- Expect to taper oral cortisone dosage slowly to prevent withdrawal syndrome (abdominal or back pain, anorexia, dizziness, fever, headache, and syncope).

## PATIENT TEACHING

- Instruct patient to take oral cortisone exactly as prescribed. Advise him to take it with food to prevent GI distress.
- Caution patient not to stop drug abruptly because doing so may lead to adrenal insufficiency, withdrawal symptoms, or both.
- Inform patient about adrenal insufficiency and need for possible dosage increases during stress. Advise him to notify prescriber immediately if signs or symptoms develop or if he's exposed to stress.
- Caution patient to avoid exposure to people with infections because cortisone can cause immunosuppression. Also, teach him to recognize and immediately report signs and symptoms of infection.
- Teach patient to recognize and report adverse reactions, including Cushing's syndrome.
- Urge patient receiving long-term cortisone therapy to carry medical identification.
- Recommend regular eye examinations.
- Urge patient to keep follow-up appointments with prescriber, which may include laboratory tests, to evaluate effects of therapy.

**crizanlizumab-tmca**

**Adakveo**

## Class and Category

*Pharmacologic class:* Monoclonal antibody (P-selectin blocker)

*Therapeutic class:* Anti-vaso-occlusive

## Indications and Dosages

- *To reduce the frequency of vaso-occlusive crises in patients with sickle cell disease*

## **I.V. INFUSION**

**Adults and adolescents age 16 and older.** 5 mg/kg infused over 30 min at wk 0, wk 2, and every 4 wk thereafter.

## **Mechanism of Action**

Binds to P-selectin to block interactions with its ligands, including P-selectin glycoprotein ligand 1. Binding P-selectin on the surface of the activated endothelium and platelets blocks interactions between endothelial cells, leukocytes, platelets, and red blood cells, which reduces vaso-occlusion.

## **Contraindications**

Hypersensitivity to crizanlizumab-tmca or its components

## **Interactions**

### **DRUGS**

None reported

## **Adverse Reactions**

**CNS:** Fever

**EENT:** Oropharyngeal pain

**GI:** Abdominal discomfort, pain, or tenderness; diarrhea; nausea; vomiting

**GU:** Vulvovaginal pruritus

**MS:** Arthralgia, back pain, musculoskeletal chest pain, myalgia

**SKIN:** Pruritus

**Other:** Crizanlizumab-tmca-induced antibodies, infusion-related reactions (chills, dizziness, fatigue, fever, nausea, pruritus, shortness of breath, sweating, urticaria, vomiting, wheezing), infusion-site reactions (extravasation, pain, swelling)

## Childbearing Considerations

### PREGNANCY

- Drug has potential to cause fetal harm, based on animal studies.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Calculate the number of vials needed for administration. One vial is needed for every 100 mg (10 mL) of crizanlizumab-tmca. Bring vials to room temperature for a maximum of 4 hours prior to the start of preparation (piercing the first vial). Visually inspect vials. Solution should be clear to opalescent, colorless, or may have a slightly brownish-yellow tint. Obtain a 100-ml 0.9% sodium chloride injection or 5% dextrose injection infusion bag/container made of polyvinyl chloride (PVC), polyethylene (PE), or polypropylene (PP). Remove a volume of solution from the infusion bag/container that is equal to the required volume of crizanlizumab-tmca. Withdraw the necessary amount of drug solution and

dilute by adding to the infusion bag/container. The volume added to the infusion bag/container should not exceed 96 ml. Gently invert infusion bag to mix diluted solution. Do not shake. Discard unused portion in drug vials.

- Administer crizanlizumab-tmca diluted solution as soon as possible. If not administered immediately, store prepared solution at room temperature for no more than 4.5 hours from the start of preparation (piercing the first vial) to the completion of infusion, or refrigerate for no more than 24 hours from the start of preparation (piercing the first vial) to the completion of infusion. This includes storage of the diluted solution and time to warm up to room temperature. Protect diluted solution from light during storage under refrigeration.
- Infuse diluted solution over a period of 30 minutes through an intravenous line, which must contain a sterile, nonpyrogenic 0.2-micron inline filter. Do not mix or coadminister with other drugs through the same intravenous line. After administration of drug, flush the line with at least 25 ml of 0.9% sodium chloride or 5% dextrose injection.
- Know that crizanlizumab-tmca may be given with or without hydroxyurea.
- Adjust dosage schedule for missed doses. If a dose is missed, it should be administered as soon as possible. If crizanlizumab-tmca is administered within 2 weeks after the missed dose, dosage schedule continues according to patient's original schedule. If drug is administered more than 2 weeks after the missed dose, dosing is continued every 4 weeks thereafter.

**WARNING** Monitor patient for infusion-related reactions. If severe, notify prescriber, discontinue infusion, and institute treatment protocol, as prescribed.

- Be aware that crizanlizumab-tmca interferes with automated platelet counts (platelet clumping), particularly when blood samples are collected in tubes containing EDTA, which may lead to unevaluable or falsely decreased platelet counts. Blood samples should be run within 4 hours of blood collection, or blood samples should be collected in tubes containing citrate. If needed, estimate platelet count via peripheral blood smear.

## **PATIENT TEACHING**

- Inform patient that infusion-related reactions may occur. Review these reactions with patient. Advise patient to immediately report any signs or

symptoms of an infusion-related reaction, including after leaving the healthcare facility.

- Instruct patient to inform healthcare provider that they are receiving crizanlizumab-tmca prior to any blood tests, due to the potential interference with laboratory tests used to measure platelet counts.

## crofelemer

### Mytesi

## Class and Category

*Pharmacologic class:* Botanical

*Therapeutic class:* Antidiarrheal

## Indications and Dosages

- *To provide symptomatic relief of non-infectious diarrhea in patients with HIV/AIDS on antiretroviral therapy*

### E.R. TABLETS

**Adults.** 125 mg twice daily.

## Mechanism of Action

Inhibits both the cyclic adenosine monophosphate (cAMP)-stimulated cystic fibrosis transmembrane conductance regulator (CFTR) chloride ion channel, and the calcium-activated chloride channel (CaCC) at the luminal membrane of enterocytes. By blocking chloride secretion

and accompanying high-volume water loss in diarrhea, the flow of chloride and water in the GI tract becomes normalized.

## Contraindications

Hypersensitivity to crofelemer or its components

## Interactions

None reported

## Adverse Reactions

**CNS:** Anxiety, depression, dizziness

**EENT:** Dry mouth, nasopharyngitis, sinusitis

**GI:** Abdominal distention or pain, constipation, dyspepsia, elevated bilirubin or liver enzymes, flatulence, gastroenteritis, giardiasis (intestinal parasitic infection), nausea

**GU:** Frequent daytime urination syndrome, nephrolithiasis, UTI

**HEME:** **Leukopenia**

**MS:** Arthralgia: back, extremity, or musculoskeletal pain

**RESP:** Bronchitis, cough, upper respiratory infection

**SKIN:** Acne, dermatitis

**Other:** Herpes zoster

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## **Nursing Considerations**

- Be aware that crofelemer is used only to treat noninfectious diarrhea in patients with HIV/AIDS on antiretroviral. Infectious etiologies should be ruled out before drug is started because crofelemer is not effective against infectious causes of diarrhea.
- Know that no dosage adjustment is needed related to the patient's CD4 cell count and HIV viral load.

## **PATIENT TEACHING**

- Instruct patient to swallow tablet whole, avoiding chewing or crushing tablet.
- Inform patient that crofelemer may be taken with or without food.
- Advise patient to inform prescriber if no improvement in diarrhea is noted.

**cyclobenzaprine  
hydrochloride**

**Amrix**

---

## Class and Category

*Pharmacologic class:* Tricyclic antidepressant-like agent (TCA)

*Therapeutic class:* Skeletal muscle relaxant

## Indications and Dosages

- *As adjunct to rest and physical therapy for relief of muscle spasm associated with acute, painful musculoskeletal conditions*

### **TABLETS**

**Adults and adolescents age 15 and over.** 5 mg three times daily, increased as needed to 10 mg three times daily. *Maximum:* 30 mg daily for no more than 3 wk.

***DOSAGE ADJUSTMENT*** Dosage frequency reduced in elderly patients and those with hepatic impairment.

### **E.R. CAPSULES (AMRIX)**

**Adults.** 15 mg once daily, increased to 30 mg once daily, as needed. *Maximum:* 30 mg once daily for no longer than 3 weeks.

---

Route	Onset	Peak	Duration
P.O.	1 hr	1-2 wk	12-24 hr

---

## Mechanism of Action

Acts in the brain stem to reduce or abolish tonic muscle hyperactivity. Because cyclobenzaprine doesn't act at the

neuromuscular junction or directly on skeletal muscle, it relieves muscle spasm without disrupting muscle function.

## Contraindications

Acute recovery phase of MI; arrhythmias, including heart block and other conduction disturbances; heart failure; hypersensitivity to cyclobenzaprine or its components; hyperthyroidism; MAO inhibitor use within 14 days

## Interactions

### DRUGS

*anticholinergics, antidyskinetics*: Possibly potentiated anticholinergic effects of these drugs  
*bupropion, meperidine, MAO inhibitors, selective serotonin reuptake inhibitors (SSRIs), serotonin norepinephrine reuptake inhibitors (SNRIs), tramadol, tricyclic antidepressants, verapamil*: Possibly increased risk of serotonin syndrome  
*CNS depressants including barbiturates, tricyclic antidepressants*: Possibly additive CNS depressant effects of these drugs, increased risk of adverse effects of antidepressants and cyclobenzaprine  
*guanadrel, guanethidine*: Possibly decreased or blocked antihypertensive effects of these drugs  
*MAO inhibitors*: Possibly hyperpyretic crisis, severe seizures, and death  
*tramadol*: Increased risk of seizures

### ACTIVITIES

*alcohol use*: Possibly additive CNS depression

# Adverse Reactions

**CNS:** Aggression, agitation, anxiety, asthenia, ataxia, confusion, **CVA**, delusions, depression, disorientation, dizziness, drowsiness, EEG alterations, extrapyramidal symptoms, fatigue, fever, hallucinations, headache, hypertonia, insomnia, irritability, malaise, **neuroleptic malignant syndrome**, nervousness, paranoia, paresthesia, psychosis, **seizures**, **serotonin syndrome**, syncope, thirst, tremor, vertigo, weakness

**CV:** **Arrhythmias**, including tachycardia; **heart block**; hypertension; **hypotension**; **MI**; orthostatic hypotension; palpitations; peripheral neuropathy; vasodilation

**EENT:** Blurred vision, diplopia, dry mouth, parotid swelling, **tongue** discoloration or edema, stomatitis, tinnitus transient vision loss, unpleasant taste

**ENDO:** Breast enlargement, galactorrhea, gynecomastia, hyperglycemia, **hypoglycemia**, syndrome of inappropriate ADH syndrome (SIADH)

**GI:** Anorexia, cholestasis, constipation, diarrhea, elevated liver enzymes, flatulence, gastrointestinal pain, gastritis, **hepatitis**, hiccups, indigestion, jaundice, nausea, paralytic ileus, vomiting

**GU:** Libido changes, impotence, testicular swelling urinary frequency, urine retention

**HEME:** **Bone marrow depression**, eosinophilia, **leukopenia**, **thrombocytopenia**

**MS:** Dysarthria

**RESP:** Dyspnea

**SKIN:** Diaphoresis, facial flushing, pruritus, rash, urticaria

**OTHER:** Anaphylaxis, angioedema, weight changes

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cyclobenzaprine cautiously in patients with history of low seizure threshold.
- Be aware that drug is not recommended for use in the elderly because higher plasma levels of cyclobenzaprine occurs in the elderly increasing risk of serious adverse reactions.

**WARNING** Monitor patient closely if cyclobenzaprine is being given with other serotonergic drug, especially when treatment is started and during dosage increases, because of the potential for life-threatening serotonin syndrome to develop. Assess patient for autonomic instability, mental status changes, and nervous system abnormalities. If present, stop both cyclobenzaprine and other serotonergic drugs immediately and notify prescriber. Provide supportive care, as ordered.

- Take safety precautions to prevent falls if patient is confused, dizzy, or weak.

## PATIENT TEACHING

- Urge patient to avoid alcohol and other CNS depressants during therapy.
- Inform patient about possible lack of alertness and dexterity.
- Advise patient to ask for assistance with walking, driving, or hazardous activities if he experiences dizziness or weakness.

**cyclosporine**

**(cyclosporin A)**

**Gengraf, Neoral, Sandimmune**

## Class and Category

*Pharmacologic class:* Polypeptide

*Therapeutic class:* Antipsoriatic, antirheumatic, immunosuppressant

## Indications and Dosages

- *To prevent or treat organ rejection in heart, kidney, and liver allogenic transplantation*

**CAPSULES, MODIFIED CAPSULES, MODIFIED  
ORAL SOLUTION, ORAL SOLUTION**

**Adults and children.** *Initial:* 15 mg/kg as a single dose 4 to 12 hr before transplantation, followed by 15 mg/kg once daily postoperatively for 1 to 2 wk and then tapered by 5%/wk to maintenance dose. *Maintenance:* 5 to 10 mg/kg daily in divided doses every 12 hr.

## **I.V. INFUSION**

**Adults.** 5 to 6 mg/kg daily and infused over 2 to 6 hr starting 4 to 12 hr before surgery. Postoperatively 5 to 6 mg/kg once daily and infused over 2 to 6 hr until patient can tolerate oral form of drug.

- *To treat severe rheumatoid arthritis*

## **MODIFIED CAPSULES, MODIFIED ORAL SOLUTION**

**Adults.** 2.5 mg/kg daily in divided doses every 12 hr, increased by 0.5 to 0.75 mg/kg daily after 8 wk and again after 12 wk. *Maximum:* 4 mg/kg daily.

- *To treat severe plaque psoriasis in non-immunocompromised patients who have failed to respond to at least one systemic therapy or in patients for whom other systemic therapies are contraindicated, or cannot be tolerated*

## **MODIFIED CAPSULES, MODIFIED ORAL SOLUTION**

**Adults.** *Initial:* 2.5 mg/kg daily in divided doses twice daily, increased by 0.5 mg/kg daily after 4 wk. Then dosage increased every 2 wk, if needed. *Maximum:* 4 mg/kg daily.

***DOSAGE ADJUSTMENT*** For patients with severe liver dysfunction, dosage reduced. For patients receiving cyclosporine to treat psoriasis or rheumatoid arthritis and experiencing serious adverse reactions, dosage reduced

25% to 50% in effort to bring adverse reactions under control.

## **Mechanism of Action**

Causes immunosuppression by inhibiting the proliferation of T lymphocytes, the production and release of lymphokines, and the release of interleukin-2, responsible for organ rejection and in disease processes such as psoriasis and rheumatoid arthritis.

## **Contraindications**

Abnormal renal function, neoplastic diseases, and uncontrolled hypertension in patients with psoriasis or rheumatoid arthritis (modified capsules and oral solution); hypersensitivity to cyclosporine, its components, or polyoxyethylated castor oil (all indications; I.V. infusion for castor oil)

## **Interactions**

### **DRUGS**

*ACE inhibitors, angiotensin II receptor antagonists, potassium-sparing diuretics, potassium supplements:* Increased risk of hyperkalemia  
*aliskiren, ambrisentan, bosentan, colchicine, CYP3A4 substrates, dabigatran, digoxin, daunorubicin, doxorubicin, etoposide, HMG-CoA reductase inhibitors (statins), methotrexate, mitoxantrone, NSAIDs, organic anion transporter protein substrates, P-glycoprotein substrates, prednisolone, repaglinide, sirolimus:* Increased blood concentrations of these drugs and possible toxicity

*allopurinol, amiodarone, azithromycin, bromocriptine, clarithromycin, colchicine, danazol, diltiazem, erythromycin, fluconazole, HIV protease inhibitors, imatinib, itraconazole, ketoconazole, methylprednisolone, metoclopramide, nefazodone, nicardipine, oral contraceptives, quinupristin and dalfopristin, verapamil, voriconazole: Increased cyclosporine level*  
*amphotericin B, azapropazone, cimetidine, ciprofloxacin, colchicine, co-trimoxazole, diclofenac, fibric acid derivatives (bezafibrate, fenofibrate), gentamicin, ketoconazole, melphalan, naproxen, NSAIDs, sirolimus, sulindac, tacrolimus, tobramycin, vancomycin: Increased risk of nephrotoxicity*  
*atorvastatin, fluvastatin, lovastatin, pravastatin, simvastatin: Risk of myotoxicity*  
*bosentan, carbamazepine, nafcillin, octreotide, orlistat, oxcarbazepine, phenobarbital, phenytoin, rifampin, St. John's wort, sulfipyrazole, terbinafine, ticlopidine: Decreased blood cyclosporine level and therapeutic response*  
*methotrexate: Increased blood methotrexate level and risk of renal dysfunction*  
*methylprednisolone (high dose): Increased risk of seizures*  
*nifedipine: Increased risk of gingival hyperplasia*  
*other immunosuppressants: Possibly excessive immunosuppression*  
*repaglinide: Possibly increased repaglinide level and risk of hypoglycemia*  
*vaccines (killed or live virus): Possibly suppressed immune response and increased adverse effects of vaccine*

## **FOODS**

*grapefruit, grapefruit juice: Increased risk of nephrotoxicity; increased plasma concentration of*

cyclosporine

*potassium-rich foods*: Increased risk of hyperkalemia

## Adverse Reactions

**CNS:** Altered level of consciousness, confusion, **encephalopathy**, headache, **intracranial hypertension**, lethargy, loss of motor function, migraine, **neurotoxicity**, paresthesia, **progressive multifocal leukoencephalopathy**, **posterior reversible encephalopathy syndrome (PRES)**, psychiatric disturbances, **seizures**, tremor

**CV:** Chest pain, hypertension, **MI**

**EENT:** Gingival hyperplasia, optic disc edema, oral candidiasis, sinusitis, visual impairment including blindness

**ENDO:** Gynecomastia

**GI:** Cholestasis, diarrhea, **hepatitis**, **hepatotoxicity**, jaundice, **liver failure**, nausea, **pancreatitis**, vomiting

**GU:** Albuminuria, elevated serum creatinine and blood urea nitrogen levels, glomerular capillary thrombosis, hematuria, **nephropathy associated with BK virus**, **nephrotoxicity**, proteinuria, **renal failure**

**HEME:** Anemia, **leukopenia**, **thrombocytopenia**

**MS:** Lower extremity pain

**SKIN:** Acne, **cancer**, flushing, hirsutism, pruritus, rash

**Other:** **Anaphylaxis**; bacterial, fungal, protozoal, and viral infections including opportunistic infections such as polyomavirus; hyperkalemia; **hypomagnesemia**; **life-threatening infections**; **lymphoma and other malignancies**

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

# Nursing Considerations

- Be aware that capsules and oral solution aren't interchangeable with modified capsules and modified oral solution. Modified forms have greater bioavailability. Also know that Neoral is not bioequivalent to Sandimmune and requires close monitoring of blood concentration to avoid the potential of underdosing if a conversion from Neoral to Sandimmune is ordered.
- Prepare I.V. infusion by diluting each milliliter of concentrate in 20 to 100 ml of normal saline solution or D<sub>5</sub>W. Use glass containers because of possible leaching of diethylhexyphthalate from polyvinyl chloride bags into cyclosporine solution.
- Administer I.V. infusion over 2 to 6 hr. If needed, drug may be infused over 24 hr.

**WARNING** Be aware that rapid I.V. infusion may cause acute nephrotoxicity.

- Don't draw blood to measure cyclosporine level through same I.V. tubing used to administer drug, even if line was flushed after administration. Blood level may be falsely elevated.
- Discard diluted solution after 24 hours.

- Be aware that intravenous and oral solutions contain alcohol and shouldn't be administered to patient who drinks heavily or has a history of alcohol dependence. In addition, these forms of cyclosporine should not be used in patients in whom alcohol intake should be avoided or minimized, such as breastfeeding or pregnant women, patients with epilepsy or liver disease, and children. Be aware that for an adult weighing 70 kg or 150 pounds, the maximum daily oral dose would deliver about 6% and a daily intravenous dose would deliver about 15% of the amount of alcohol contained in a standard drink.
- Don't add water to oral solution because it will alter drug's effectiveness.
- Avoid giving oral cyclosporine with grapefruit juice, which may raise trough level, increasing risk of nephrotoxicity.

**WARNING** Monitor patient closely for hypersensitivity reactions, especially at the beginning of cyclosporine therapy and for at least the first 30 minutes following the start of an intravenous dose and then frequently thereafter. Know that while anaphylaxis may rarely occur, anaphylactic reactions have not occurred with the use of soft gelatin capsules or oral solution that did not contain Cremophor EL (polyoxyethylated castor oil). If anaphylaxis occurs, stop drug immediately and be prepared to administer epinephrine and oxygen, as ordered.

- Monitor blood pressure, especially in patients with a history of hypertension, because drug can worsen this condition. Expect to decrease dosage if hypertension develops.
- Monitor liver and renal function tests, as ordered, to detect decreased function. Be aware that it is not unusual for serum creatinine and BUN levels to be elevated during cyclosporine therapy. These elevations warrant investigation but do not always reflect kidney transplant rejection. If not related to rejection, a dosage reduction of cyclosporine often helps to decrease these levels.
- Be aware that an association between the development of interstitial fibrosis and higher cumulative doses or persistently high circulating trough concentrations of cyclosporine, especially during first 6 months post-transplant, may increase the risk of chronic nephrotoxicity.

- Be aware that although uncommon, cyclosporine may cause neurotoxicity, especially after liver transplantation. Watch for evidence of encephalopathy (impaired consciousness, loss of motor function, psychiatric disturbance, seizures, visual disturbance). Notify prescriber immediately if present, and expect cyclosporine dosage to be decreased or the drug discontinued to increase possibility of a reversible or improvement of encephalopathy. Also monitor patients closely for seizures, especially if they are also receiving high-dose methylprednisolone therapy.
- Be aware that cyclosporine use may result in increased serum cholesterol levels.
- Be aware that St. John's wort may decrease blood cyclosporine level.
- Store capsules at 25°C (77°F) in prepackaged foil wrap to protect them from light.
- Expect about 50% of patients treated for psoriasis to relapse about 4 months after therapy stops. Know that patients with chronic plaque psoriasis may develop erythrodermic psoriasis or generalized pustular psoriasis when cyclosporine dose is reduced or drug is discontinued.

**WARNING** Watch for evidence of infection (such as cough, fever, malaise, pain) because patients receiving immunosuppressants such as cyclosporine are at increased risk for bacterial, fungal, parasitic, and viral infection. Watch for both generalized and localized infections, including worsening of preexisting infections, and be aware that these infections may become life-threatening. Activation of latent viral infections may also occur and include BK virus-associated nephropathy that can lead to decreased renal function and renal graft loss.

## **PATIENT TEACHING**

- Instruct patient to take drug at same time each day and in same relation to type and timing of food intake to help increase compliance and maintain steady blood level.
- Advise patient to mix oral solution in a glass—not plastic—container with room-temperature orange or apple juice to improve flavor. Caution him to

avoid grapefruit juice because it alters drug metabolism.

- Instruct patient to use syringe supplied by manufacturer to ensure accurate measurement of oral solution dose and to wipe—not rinse—syringe after use to prevent cloudiness.
- Advise patient not to stop taking drug without consulting prescriber.
- Instruct patient to avoid virus vaccines during therapy and people who have received such vaccines. Or, suggest wearing a protective mask when he's around them.
- Caution patient to avoid people who have infections during therapy because cyclosporine causes immunosuppression.
- Advise good dental hygiene because of risk of gingival hyperplasia.
- Advise patient to discard oral solution after it has been opened for 2 months.
- Inform patient with rheumatoid arthritis that drug effects may not appear for 4 to 6 weeks.
- Caution patient to avoid excessive exposure to ultraviolet light.

# D

## dabigatran etexilate

**Pradaxa**

### Class and Category

*Pharmacologic class:* Direct thrombin inhibitor

*Therapeutic class:* Anticoagulant

### Indications and Dosages

- *To reduce the risk of stroke and systemic embolism in patients with nonvalvular atrial fibrillation*

#### CAPSULES

**Adults with creatinine clearance greater than 30 ml/min.** 150 mg twice daily.

**Adults with creatinine clearance between 15 and 30 ml/min.** 75 mg twice daily.

***DOSAGE ADJUSTMENT*** For patient with a creatinine level between 30 and 50 ml/min and taking dronedarone or systemic ketoconazole concomitantly, dosage decreased to 75 mg twice daily.

- *To treat deep vein thrombosis and pulmonary emboli in patients who have been treated with a parenteral anticoagulant for 5 to 10 days; to reduce risk of*

*recurrence of deep vein thrombosis and pulmonary emboli in patients who have been previously treated*

## **CAPSULES**

**Adults with creatinine clearance greater than 30 ml/min.** 150 mg twice daily.

- *To prevent deep vein thrombosis and pulmonary embolism following a hip replacement*

## **CAPSULES**

**Adults with creatinine clearance greater than 30 ml/min.** 110 mg 1 to 4 hr after surgery and after hemostasis has been achieved on first day, then 220 mg once daily for 28 to 35 days.

***DOSAGE ADJUSTMENT*** For patient with creatinine clearance less than 50 ml/min and prescribed a P-gp inhibitor, dabigatran discontinued.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr (fasting) 2 hr (after high-fat meal)	Unknown

## **Mechanism of Action**

Directly inhibits thrombin from converting fibrinogen into fibrin during the coagulation cascade. Inhibition of this activity prevents the development of a blood clot.

## **Contraindications**

Active pathologic bleeding, hypersensitivity to dabigatran or its components, presence of mechanical prosthetic heart valve

# Interactions

## DRUGS

*P-gp inducers such as rifampin:* Decreased exposure to dabigatran

*P-gp inhibitors such as dronedarone, ketoconazole:*  
Increased exposure to dabigatran in patients with renal impairment

## Adverse Reactions

**CNS:** Intracranial or intraspinal hemorrhage

**CV:** Pericardial bleeding

**EENT:** Intraocular bleeding

**GI:** Diarrhea, dyspepsia, esophageal ulcer, gastritis-like symptoms, gastrointestinal hemorrhage, nausea, retroperitoneal bleeding, upper abdominal pain

**HEME:** Bleeding (serious), thrombocytopenia

**MS:** Intra-articular bleeding, intramuscular bleeding with compartment syndrome

**SKIN:** Pruritus, rash, urticaria

**Other:** Anaphylactic reaction or shock, angioedema

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm although the use of anticoagulants such as dabigatran may increase risk of bleeding in the fetus.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.

## **LABOR & DELIVERY**

- Drug may cause maternal bleeding and hemorrhage if given during labor and delivery.
- Know that drug should be temporarily withheld or a shorter acting anticoagulant substituted as delivery approaches or if neuraxial anesthesia is expected to be used during delivery.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## **Nursing Considerations**

- Be aware that dabigatran should not be used in patients with triple-positive antiphospholipid syndrome because of increased risk for recurrent thrombosis.
- Assess renal function, as ordered, prior to beginning dabigatran therapy because dose is based on the patient's creatinine level. Continue to monitor the patient's serum creatinine level throughout therapy, as ordered, and expect frequency of serum creatinine tests to increase if patient develops a condition that affects renal function because a dosing adjustment may be required. Know that the drug should be discontinued if the patient develops acute renal failure.
- Be aware that patients converting from warfarin to dabigatran therapy should begin dabigatran therapy when their international normalized ratio (INR) is below 2.0.
- Expect patients converting from dabigatran to warfarin therapy to do so based on their creatinine clearance level. For patients who have a creatinine clearance level greater than 50 ml/min, expect warfarin to be started 3 days before dabigatran is discontinued. For patients who have a creatinine clearance level of 31 to 50 ml/min, expect warfarin to be started 2 days before dabigatran is discontinued. For patients who have a creatinine clearance level of 15 to 30 ml/min, expect warfarin to be started 1 day before dabigatran is discontinued. No recommendations are available for patients who have a creatinine clearance level of less than 15 ml/min.

- Be aware that degree of anticoagulation does not need to be assessed by routine laboratory testing with dabigatran use. However, when necessary, expect the prescriber to use activated partial thromboplastin time (aPTT) or ecarin clotting time (ECT), and not INR, to assess for anticoagulant activity for the patient receiving dabigatran therapy.
- Know that dabigatran can elevate the patient's INR. Therefore, when patients are transitioned, dabigatran must be stopped for at least 2 days before the most accurate effects of warfarin can be known.
- Begin dabigatran therapy, as ordered, for a patient currently receiving a parenteral anticoagulant, such as heparin, within 2 hours before the next dose of the parenteral drug was to have been administered. If the parenteral anticoagulant being used is continuous in nature, expect to begin dabigatran therapy upon discontinuation of the continuously administered parenteral anticoagulant.
- Expect to begin treatment with a parenteral anticoagulant, if ordered, 12 hours after the patient's final dabigatran dose if the patient has a creatinine clearance of 30 ml/min or greater, and 24 hours after the patient's final dabigatran dose if the patient's creatinine clearance is less than 30 ml/min.
- Know that dabigatran therapy should be discontinued, if possible, 1 to 2 days before invasive or surgical procedures for patients with a creatinine clearance of 50 ml/min or more, and 3 to 5 days for patients whose creatinine clearance is less than 50 ml/min because of the increased risk for bleeding. Longer times may be required for patients undergoing major surgery, spinal puncture, or placement of a spinal or epidural catheter or port, in whom complete hemostasis is required. If surgery cannot be postponed, monitor patient closely for bleeding and assess bleeding risk with the ECT. If an ECT measurement is not possible, know that the aPTT can provide an approximation of dabigatran's anticoagulant activity.

**WARNING** Monitor patient closely for bleeding because dabigatran increases risk for bleeding, which can become severe. Bleeding risk increases in patients taking concurrent antiplatelet drugs, fibrinolytic therapy, heparin, or with chronic use of NSAIDs. It also increases during labor and delivery. *Monitor patient very closely.* Promptly report any signs or symptoms of bleeding such as a drop in hemoglobin and/or hematocrit or the development of hypotension or overt bleeding. Expect to discontinue drug if active bleeding

occurs and is persistent or serious. Know that protamine sulfate and vitamin K will not affect the anticoagulant activity of dabigatran. Instead, the prescriber may prescribe platelet concentrates if thrombocytopenia is present or the patient has been exposed to long-acting antiplatelet drugs. If bleeding is life-threatening or uncontrolled or emergency surgery or urgent procedures are necessary, expect to administer idarucizumab to reverse the anticoagulant effect of dabigatran.

- Know that premature discontinuation of dabigatran increases the risk of thrombotic events. Be aware that patients receiving spinal/epidural anesthesia or a spinal puncture are at risk of developing an epidural or spinal hematoma, which can result in long-term or permanent paralysis. Monitor patient frequently for signs or symptoms of neurologic impairment. Notify prescriber immediately if patient complains of bladder or bowel dysfunction, midline back pain, or numbness, tingling, or weakness in the lower extremities.
- Assess patient closely for stroke if dabigatran therapy must be discontinued temporarily because of an active bleed, elective surgery, or an invasive procedure. Also, be aware that premature discontinuation of the drug increases risk of thrombotic events. Know that therapy should be restarted as soon as possible. If the drug must be discontinued for reasons other than pathological bleeding, expect patient to receive coverage with another anticoagulant to decrease the risk of thrombotic events, such as stroke.

**WARNING** Be on the alert for an epidural or spinal hematoma formation in patients receiving dabigatran and neuraxial anesthesia or undergoing spinal puncture. This hematoma may result in long-term or permanent paralysis. Assess patient frequently for signs and symptoms of neurological impairment. If present, notify prescriber immediately as urgent treatment is necessary.

## **PATIENT TEACHING**

- Tell patient to take dabigatran exactly as prescribed.
- Instruct patient to swallow capsule whole without breaking, chewing, or emptying the contents of the capsule prior to ingestion.
- Tell patient that if she misses a dose, she should take it as soon as she remembers on the same day she missed the dose, unless it is within 6 hours of the next dose. She should never double a dose to make up for a missed dose.
- Instruct patient to keep bottle tightly closed when not in use and store in the original package to protect from moisture. Have patient date bottle when opened and tell her to discard any remaining drug if not used within 4 months of initially opening the bottle.
- Urge patient to take precautions against bleeding, such as using an electric shaver and a soft-bristled toothbrush.
- Caution patient to avoid activities that could cause traumatic injury and bleeding.
- Urge patient to notify prescriber immediately about unusual bleeding and any unexplained symptoms, such as abnormal vaginal bleeding; dizziness; easy bruising; gum bleeding; red or dark brown urine; stools that are black or tarry; vomiting blood or vomit that looks like coffee grounds; and weakness.
- Caution patient not to stop taking dabigatran abruptly.
- Urge patient to carry medical identification that reveals she is taking dabigatran.
- Tell patient to inform all healthcare providers that she is taking dabigatran and not to take any medication, including OTC drugs, without first consulting the prescriber.
- Warn mothers not to breastfeed while taking dabigatran because of increased risk of bleeding in the infant.

**daclatasvir**

**Daklinza**

# Class and Category

*Pharmacologic class:* Hepatitis C virus NS5A inhibitor

*Therapeutic class:* Antiviral

## Indications and Dosages

- *As adjunct to treat chronic hepatitis C virus (HCV) genotype 1 or genotype 3 infection concomitantly with sofosbuvir therapy and with or without ribavirin therapy*

### **TABLETS**

**Adults.** 60 mg once daily for 12 wk.

***DOSAGE ADJUSTMENT*** For patients taking certain HIV antiviral agents such as atazanavir with ritonavir, indinavir, nelfinavir, or saquinavir and strong CYP3A inhibitors, dosage reduced to 30 mg once daily. For patients taking moderate CYP3A inducers or nevirapine, dosage increased to 90 mg once daily.

## Mechanism of Action

Inhibits both viral RNA replication and virion assembly against the hepatitis C virus to destroy it.

## Contraindications

Concurrent therapy with drugs that strongly induce CYP3A, such as carbamazepine, phenytoin, rifampin, or St. John's wort; hypersensitivity to daclatasvir or its components

## Interactions

## DRUGS

*amiodarone, sofosbuvir*: Increased risk of significant bradycardia

*buprenorphine, buprenorphine/naloxone*: Possible increased risk of buprenorphine-associated adverse reactions

*dabigatran etexilate mesylate*: Increased plasma dabigatran level with increased risk of adverse reactions

*digoxin*: Increased risk of digitalis toxicity

*HMG-CoA reductase inhibitors such as atorvastatin, fluvastatin, pitavastatin, pravastatin, rosuvastatin, simvastatin*: Increased plasma concentration of HMG-CoA reductase inhibitors with increased risk of adverse reactions.

*moderate CYP3A inducers such as bosentan, dexamethasone, modafinil, nafcillin, rifapentine; non-nucleoside reverse transcriptase inhibitors (NNRTI) such as efavirenz, etravirine, nevirapine*: Possibly decreased plasma daclatasvir level with possible decreased effectiveness

*other antiretrovirals such as atazanavir/cobicistat, elvitegravir/cobicistat/emtricitabine/tenofovir disoproxil fumarate; protease inhibitors such as atazanavir with ritonavir, indinavir, nelfinavir, saquinavir; strong CYP3A inhibitors such as clarithromycin, itraconazole, ketoconazole, nefazodone, posaconazole, telithromycin, voriconazole*: Possibly increased plasma daclatasvir level with possible increased risk of adverse reactions

## Adverse Reactions

**CNS:** Dizziness, fatigue, headache, insomnia, somnolence

**CV:** **Bradycardia**

**GI:** Diarrhea, elevated liver and pancreatic enzymes, hyperbilirubinemia, nausea

**HEME:** Anemia

**SKIN:** Rash

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm although when given in combination with sofosbuvir and ribavirin, it is contraindicated during pregnancy.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### **REPRODUCTION**

- Women of childbearing age should use effective contraception during combination therapy with sofosbuvir along with ribavirin and for 6 months after combination therapy has been discontinued.
- Known or suspected pregnancy should be reported immediately.

## **Nursing Considerations**

- Know that patient should be tested for hepatitis B before starting daclatasvir therapy, because HBV reactivation has occurred in HCV/HBV co-infected patients when given treatment with HCV direct-acting antivirals such as daclatasvir who were not receiving HBV antiviral therapy. Fulminant hepatitis, hepatic failure, and even death have occurred. Monitor co-infected patients for HBV reactivation or hepatitis

flare during daclatasvir therapy. If HBV infection is detected, expect treatment to be given.

- Be aware that daclatasvir must be given with sofosbuvir, with or without ribavirin, in the treatment of chronic hepatitis C. If sofosbuvir is discontinued, know that daclatasvir should also be discontinued.

**WARNING** Monitor patient's heart rate closely, as serious symptomatic bradycardia may occur because of coadministration with sofosbuvir and amiodarone. Bradycardia most often occurs during the first 2 weeks of daclatasvir therapy. Expect patient to have cardiac monitoring in an inpatient setting for the first 48 hr of daclatasvir therapy, followed by patient monitoring of pulse for the first 2 weeks of therapy. Know that patients at greater risk for bradycardia include patients receiving amiodarone or beta blocker therapy or patients who have advanced liver disease or underlying cardiac disease.

## **PATIENT TEACHING**

- Tell patient that daclatasvir is never prescribed alone to treat hepatitis C and will be combined with another drug called sofosbuvir and possibly a third drug called ribavirin.
- Instruct patient to take daclatasvir once daily at the same time every day after taking pulse.
- Stress importance of not stopping daclatasvir therapy without prescriber knowledge.
- Inform patient that HBV reactivation can occur in patients co-infected with HBV during or after treatment of HCV infection. Tell patient to inform prescriber if she has a history of hepatitis B.
- Tell patient to notify all prescribers of daclatasvir therapy, because significant drug interactions can occur between daclatasvir and many other drugs.

**WARNING** Instruct patient how to take pulse. Stress importance of patient seeking immediate medical

attention if she develops signs or symptoms of bradycardia such as chest pain, confusion, dizziness, excessive tiredness, fainting, lightheadedness, malaise, shortness of breath, or weakness.

- Instruct female patient of childbearing age to avoid pregnancy during therapy and for 6 months after completion of treatment. Tell her to notify prescriber if pregnancy occurs or is suspected.
- Advise mothers who wish to breastfeed to discuss the benefits and risks with prescriber before doing so.

## **dalbavancin**

### **Dalvance**

## **Class and Category**

*Pharmacologic class:* Lipoglycopeptide

*Therapeutic class:* Antibacterial antibiotic

## **Indications and Dosages**

- *To treat acute bacterial skin and skin structure infections caused by Enterococcus faecalis (vancomycin susceptible strains), Staphylococcus aureus (including methicillin-susceptible and methicillin-resistant strains), Streptococcus agalactiae, S. anginosus group (including S. anginosus, S. constellatus, and S. intermedius), S. dysgalactiae, and S. pyogenes*

## I.V. INFUSION

**Adults.** 1,500 mg infused as a single dose over 30 min. Alternatively, 1,000 mg infused over 30 min, followed by 500 mg infused over 30 min 1 wk later.

**DOSAGE ADJUSTMENT** For patients with renal impairment (creatinine clearance less than 30 ml/min) and who are not receiving hemodialysis, initial dosage reduced to 1,125 mg as a single dose or 750 mg, followed by 375 mg 1 wk later.

## Mechanism of Action

Interferes with bacterial cell wall synthesis, which leads to impaired bacterial cell growth or cell death.

## Incompatibilities

Do not co-infuse with other medications or electrolytes. Also, do not mix or infuse with saline-based infusion solutions because a precipitation may occur.

## Contraindications

Hypersensitivity to dalbavancin or its components

## Interactions

None reported

## Adverse Reactions

**CNS:** Dizziness, headache

**EENT:** Oral candidiasis

**ENDO:** Hypoglycemia

**GI:** Abdominal pain, *Clostridium difficile*-associated colitis, diarrhea, elevated liver enzymes, gastrointestinal hemorrhage, hepatotoxicity, melena, nausea, passage of bright red blood through anus

**GU:** Vulvovaginal mycotic infection

**HEME:** Anemia, elevated international normalized ratio (INR), eosinophilia, hemorrhagic anemia, leukopenia, neutropenia, spontaneous hematoma, thrombocytosis, thrombocytopenia

**MS:** Back pain

**RESP:** Bronchospasm

**SKIN:** Flushing of upper body, petechiae, pruritus, rash, urticaria

**Other:** Anaphylaxis, phlebitis, red man syndrome (with rapid infusion), wound hemorrhage

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cautiously in patients with a history of glycopeptides allergy because of a possibility of cross-sensitivity.

- Use cautiously in patients with a history of hepatic impairment because dosing adjustments for dalbavancin in patients with moderate to severe hepatic impairment are not known. Dosage adjustment is not required for patients with mild hepatic impairment.
- Reconstitute with 25 ml of sterile water for injection, USP for each 500-mg vial. Avoid foaming by alternating between gently swirling and inverting the vial until contents are completely dissolved. Do not shake. Solution should appear clear and colorless to yellow. Once reconstituted, the vial may be refrigerated for up to 48 hours. Do not freeze. Prior to administration, further dilute reconstituted vial by aseptically transferring the required dose from the vial to an intravenous bag or bottle containing enough solution of 5% dextrose injection, USP to provide a final dalbavancin concentration of 1 to 5 mg/ml. Discard any unused portion of the reconstituted solution. Once diluted, the intravenous bag or bottle may be refrigerated until administration as long as the total time from the vial being reconstituted until administration does not exceed 48 hours. Never freeze the diluted solution.
- Administer as an intravenous infusion over 30 minutes to minimize the risk of infusion-related reactions that resemble red man syndrome, such as flushing of the upper body, pruritus, rash, or urticaria. Monitor patient for back pain, which also has been identified as an infusion-related reaction. If present, stopping or slowing the infusion may cause these reactions to disappear. Always flush intravenous line with 5% dextrose injection, USP before and after administration if the line is used to administer other drugs.
- Assess patient for signs of secondary infection, such as profuse, watery diarrhea. If such diarrhea develops, contact prescriber and expect to obtain a stool specimen to rule out pseudomembranous colitis caused by *C. difficile*. If diarrhea occurs, notify prescriber and expect to withhold dalbavancin and treat patient with an antibiotic effective against *C. difficile* along with electrolytes, fluids, and protein.

## PATIENT TEACHING

- Emphasize importance of obtaining second dose of dalbavancin if patient was prescribed the two-dose regimen.
- Tell patient to immediately report any signs and symptoms of an allergic reaction.
- Advise patient to report severe diarrhea to prescriber immediately.

# dalteparin sodium

(tedelparin)

**Fragmin**

## Class and Category

*Pharmacologic class:* Low-molecular-weight heparin

*Therapeutic class:* Anticoagulant

## Indications and Dosages

- *To prevent ischemic complications in patients who receive aspirin as part of treatment for unstable angina and non-Q-wave MI*

### SUBCUTANEOUS INJECTION

**Adults.** 120 international units/kg every 12 hr with aspirin (75 to 165 mg daily) until patient is stable, usually 5 to 8 days. *Maximum:* 10,000 international units/dose.

- *To prevent deep vein thrombosis in patients undergoing hip replacement surgery*

### SUBCUTANEOUS INJECTION

**Adults.** *Initial:* 2,500 international units 4 to 8 hr after surgery (or later if hemostasis has not been achieved) and then 5,000 international units once daily for 5 to 10 days postoperatively or 2,500 international units 1 to 2 hr before surgery, repeated in 4 to 8 hr after surgery and then 5,000 international units once daily for 5 to 10 days

postoperatively. Alternatively, 5,000 international units the evening before surgery followed by 5,000 international units 4 to 8 hr after surgery and then 5,000 international units once daily for 5 to 10 days postoperatively.

- *To prevent deep vein thrombosis in patients undergoing abdominal surgery who are at risk for thromboembolic complications*

## **SUBCUTANEOUS INJECTION**

**Adults.** 2,500 international units daily, starting 1 to 2 hr before surgery and repeated once daily postoperatively for 5 to 10 days.

***DOSAGE ADJUSTMENT*** For patients at high risk (i.e., those with cancer), 5,000 international units the evening before surgery, repeated once daily postoperatively for 5 to 10 days; or alternatively for patients with cancer, 2,500 international units 1 to 2 hr before surgery followed by 2,500 international units 12 hr later and then 5,000 international units once daily postoperatively for 5 to 10 days.

- *To prevent deep vein thrombosis in patients with severe mobility restrictions during acute illness*

## **SUBCUTANEOUS INJECTION**

**Adults.** 5,000 international units once daily for 12 to 14 days.

- *To provide extended treatment of symptomatic venous thromboembolism in patients with cancer*

## **SUBCUTANEOUS INJECTION**

**Adults.** 200 international units/kg once daily for 30 days. Then 150 international units/kg once daily for 5 more months.

*Maximum: 18,000 international units daily.*

➤ *To treat symptomatic venous thromboembolism in pediatric patients*

## **SUBCUTANEOUS INJECTION**

**Children age 8 to 17 years.** 100 IU/kg twice daily.

**Children 2 years to less than 8 years.** 125 IU/kg twice daily.

**Infants 4 weeks to children less than 2 years.** 150 IU/kg twice daily.

***DOSAGE ADJUSTMENT*** For adult patient with thrombocytopenia and cancer who experiences a platelet count between 50,000 and 100,000/mm<sup>3</sup>, dosage reduced by 2,500 international units until platelet count recovers to or above 100,000 mm<sup>3</sup>. For adult patient with thrombocytopenia and cancer who experiences a platelet count less than 50,000 mm<sup>3</sup>, dalteparin withheld until platelet count is above 50,000 mm<sup>3</sup>. For children 4 weeks and older, who experiences a platelet count between 50,000 and 100,000/mm<sup>3</sup>, dosage reduced by 50%. For children 4 weeks and older, who experiences a platelet count less than 50,000 mm<sup>3</sup>, dalteparin withheld until platelet count is above 50,000 mm<sup>3</sup>. For adult patient needing extended treatment of acute symptomatic venous thrombosis and having severely impaired renal function (creatinine clearance below 30 ml/min), anti-Xa levels monitored to determine appropriate dose. Target anti-Xa range is 0.5 to 1.5 international units/ml.

## **Mechanism of Action**

Binds to and accelerates the activity of antithrombin III, thus inhibiting thrombin and blocking the formation of fibrin clots.

# Incompatibilities

Don't mix dalteparin with other drugs.

# Contraindications

Active major bleeding; history of heparin-induced thrombocytopenia or heparin-induced thrombocytopenia with thrombosis; hypersensitivity to dalteparin, heparin, or pork products; treatment for unstable angina and non-Q-wave MI or for prolonged venous thromboembolism prophylaxis while undergoing epidural/neuraxial anesthesia

# Interactions

## DRUGS

*NSAIDs, oral anticoagulants, platelet aggregation inhibitors, thrombolytics:* Possibly increased risk of hemorrhage and spinal or epidural hematoma

# Adverse Reactions

**EENT:** Epistaxis

**GI:** Elevated liver enzymes

**HEME:** Hemorrhage, thrombocytopenia

**MS:** Osteoporosis

**SKIN:** Alopecia, bullous eruption, necrosis, pruritus, rash

**Other:** Anaphylaxis; injection-site bruising, hematoma and pain

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm although it has the potential for adverse effects on preterm infants when used in pregnancy if the 3.8 ml multiple dose vial of the drug is because it contains benzyl alcohol.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Use dalteparin with extreme caution in patients with a history of heparin-induced thrombocytopenia; those at increased risk for hemorrhage (such as those who use a platelet inhibitor or have active ulcerative GI disorder, bacterial endocarditis, bleeding disorders, hemorrhagic stroke, or uncontrolled hypertension); and those with recent brain, eye, or spinal surgery.
- Use drug cautiously in patients with bleeding diathesis, diabetic retinopathy, platelet defects, recent GI bleeding, severe hepatic or renal insufficiency, or thrombocytopenia.
- Inform Jewish or Islamic patients that drug comes from porcine intestine before giving first dose.

**WARNING** Question patient regarding use of aspirin and other NSAIDs, platelet inhibitors or other anticoagulants prior to dalteparin therapy that may increase risk of bleeding.

- Be aware that risk factors for thromboembolic events include age over 40, cancer, history of deep vein thrombosis or pulmonary embolism, obesity,

and planned use of anesthesia for more than 30 minutes.

- Don't give drug by I.M. or I.V. injection.
- Administer drug deep into subcutaneous tissue in U-shaped area around navel, upper outer thigh, or upper outer quadrant of buttocks with patient seated. If using area around navel or on thigh, lift skin fold with thumb and forefinger while giving injection. Insert entire length of needle at a 45- to 90-degree angle. Rotate sites daily.
- Know that routine coagulation tests and dosage adjustments usually aren't required. Instead, anti-Xa levels are measured, prior to the fourth dose and as needed. Samples should be drawn 4 hours after drug administration. Dosages are then adjusted in increments of 25 IU/kg to achieve target anti-Xa level between 0.5 and 1 IU/ml. Thereafter anti-Xa levels are measured periodically for children and in adults with severe renal impairment or if abnormal coagulation parameters or bleeding occurs during drug therapy.

**WARNING** Monitor patient receiving dalteparin and epidural or spinal anesthesia or spinal puncture because spinal hematomas can occur, causing long-term or permanent paralysis. Watch for evidence of neurologic impairment, such as changes in motor or sensory. If present, notify prescriber immediately; patient needs urgent care to minimize effect of hematoma. Use of indwelling epidural catheters; concurrent use of other drugs that affect hemostasis such as nonsteroidal anti-inflammatory drugs, platelet inhibitors, and other anticoagulants; a history of traumatic or repeated epidural or spinal punctures; or a history of spinal deformity or spinal surgery increase the risk of spinal or epidural hematoma in patients receiving dalteparin.

## **PATIENT TEACHING**

- Teach patient or caregiver administering drug at home how to select injection sites, give subcutaneous injections, and rotate sites daily. Tell patient to discard drug if it's discolored or contains particles. Review safe handling and disposal of syringes and needles.

- Teach patient to store drug at room temperature, away from moisture and heat.
- Urge patient to report adverse reactions, especially bleeding, and to seek help immediately if signs of blood clots develop, such as severe difficulty breathing or changes in mental status or motor or sensory abnormalities.
- Instruct patient to inform all dentists and prescribers of dalteparin therapy. Tell patient who is receiving spinal anesthesia or a spinal puncture to alert medical staff immediately if he experiences muscular weakness, numbness (especially in his legs), or tingling following the procedure.
- Emphasize the importance of follow-up visits.

## dapagliflozin

**Farxiga**

### Class and Category

*Pharmacologic class:* Sodium glucose co-transporter 2 inhibitor

*Therapeutic class:* Antidiabetic

### Indications and Dosages

- *Adjunct to diet and exercise to improve glycemic control in patients with type 2 diabetes mellitus*

#### **TABLETS**

**Adults.** 5 mg once daily in morning, increased to 10 mg once daily in morning, as needed.

- *To reduce risk of hospitalization for heart failure in patients with type 2 diabetes mellitus and established cardiovascular disease or presence of multiple cardiovascular risk factors*

## **TABLETS**

**Adults.** 10 mg once daily.

## **Mechanism of Action**

Inhibits sodium glucose co-transporter 2 in the kidneys, which prevents glucose reabsorption. This decreases blood glucose levels.

## **Contraindications**

Dialysis therapy, end-stage renal disease, hypersensitivity to dapagliflozin or its components, severe renal impairment (glomerular filtration rate less than 30 ml/min)

## **Interactions**

### **DRUGS**

*insulin, insulin secretagogues:* Increased risk of hypoglycemia

## **Adverse Reactions**

**CNS:** Syncope

**CV:** Dyslipidemia, elevated low-density lipoprotein cholesterol, **hypotension**

**EENT:** Nasopharyngitis

**ENDO:** **Hypoglycemia, ketoacidosis**

**GI:** Constipation, nausea

**GU:** **Acute kidney injury**, decreased glomerular filtration rate, dysuria, elevated serum creatinine levels, genital mycotic infections, impaired renal function, increased urination, **necrotizing fasciitis of the perineum (Fournier's gangrene)**, osmotic diuresis, **potential bladder cancer**, pyelonephritis, **urosepsis**, UTI

**HEME:** Elevated hematocrit level

**MS:** Back or extremity pain

**SKIN:** **Severe cutaneous reactions**, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, dehydration, elevated serum phosphorus levels

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Drug is not recommended for use during the second and third trimesters of pregnancy because of potential adverse renal effects as seen in animal studies.

### LACTATION

- It is not known if drug is present in breast milk.
- Drug should not be used during breastfeeding because of the potential for adverse renal effects in the breastfed infant since renal maturation continues for up to 2 years after birth.

## Nursing Considerations

- Use drug cautiously in patients with chronic kidney insufficiency, congestive heart failure, decreased blood volume, and patients taking medications such as angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, diuretics, and NSAIDs because these

conditions and treatments may predispose the patient to acute kidney injury while receiving dapagliflozin. Ensure that kidney function has been assessed prior to starting dapagliflozin therapy and then periodically thereafter.

- Know that dapagliflozin should not be given to patients with active bladder cancer, as it is not known if the drug has an effect on preexisting bladder tumors. Use cautiously in patients with a history of bladder cancer. Monitor patient throughout therapy for hematuria, as this is a potential indicator for the presence of bladder tumor.
- Assess patient's kidney function and volume status and correct, if needed and as prescribed, prior to starting dapagliflozin therapy, because drug can cause intravascular volume contraction leading to acute kidney injury or symptomatic hypotension. Patients at highest risk include elderly patients, patients receiving loop diuretic therapy or drugs that interfere with the renin-angiotensin-aldosterone system, and patients who have low systolic blood pressure or impaired renal function. Expect renal function to be evaluated periodically throughout drug therapy.
- Expect drug to be temporarily discontinued in patients who experience a reduced oral intake, such as with an acute illness or fasting, or who experience excessive fluid losses because of significant gastrointestinal illness or heat exposure, to reduce risk of acute kidney injury.
- Monitor patient's blood pressure and cholesterol level throughout dapagliflozin therapy.

**WARNING** Monitor patient for hypersensitivity reactions.

Although rare, anaphylaxis, angioedema, and severe cutaneous adverse reactions have occurred. If present, stop drug immediately and notify prescriber. Provide care, as prescribed, according to the standard of care until signs and symptoms subside.

- Be aware that patients receiving insulin or insulin secretagogues may require a lower dose of these agents because dapagliflozin in combination increases risk of hypoglycemia. Monitor patient closely for hypoglycemia. If present, treat according to standard of care and notify prescriber.

**WARNING** Monitor patient for a rare but serious and life-threatening necrotizing infection of the perineum called Fournier's gangrene. Notify prescriber immediately if patient develops erythema, pain, swelling, or

tenderness in the genital or perineal area, along with fever or malaise. Expect treatment with broad-spectrum antibiotics and, if needed, surgical debridement of the area. Know that dapagliflozin will be discontinued if this occurs. Monitor patient's blood glucose levels closely and expect an alternative treatment for glycemic control.

- Monitor patients for genital mycotic infections, especially those with a history of such infections. If present, notify prescriber and treat, as prescribed.

**WARNING** Monitor patient closely for ketoacidosis that may occur despite the patient having type 2 diabetes and may be present even if a blood glucose level is less than 250 mg/dl. If signs and symptoms occur such as dehydration, fruity odor to breath, malaise, nausea, shortness of breath, and vomiting notify prescriber and expect drug to be discontinued. Provide supportive care, as ordered.

## **PATIENT TEACHING**

- Inform patient that dapagliflozin therapy is not a replacement for diet and exercise therapy.
- Instruct patient on the signs and symptoms of hypoglycemia and how to treat it. Inform patient who is also receiving a sulfonylurea or insulin that the risk of hypoglycemia is greater. Tell patient to notify prescriber if hypoglycemia occurs frequently or is severe.
- Inform patient that dapagliflozin may have an adverse effect on the bladder, increasing the risk for bladder cancer. Tell patient to report blood in the urine immediately to the prescriber.
- Tell patient to monitor the blood glucose level using blood tests instead of urine tests because the drug increases urinary glucose excretion and will lead to positive urine glucose tests. Review signs and symptoms of ketoacidosis with patient and urge her to seek immediate medical attention, if present, even if blood glucose level is less than 250 mg/dl.

- Instruct patient to stop taking drug and seek immediate medical attention if an allergic reaction such as hives or facial or throat swelling occurs while taking dapagliflozin.
- Advise female patients to notify prescriber if pregnancy occurs or is suspected because the drug may cause fetal harm if taken in the second or third trimester. Also, inform female patients that drug may cause harm to infants who are breastfed. Mothers should discuss desire to breastfeed with prescriber prior to breastfeeding.
- Advise patient to maintain adequate fluid intake throughout dapagliflozin therapy. However, tell patient to notify prescriber if he is unable to take a normal amount of daily fluids due to illness or fasting or experiences an excessive loss of fluids from excessive perspiration or gastrointestinal illnesses, as drug may need to be temporarily withheld.

**WARNING** Warn patient to stop dapagliflozin and seek immediate medical attention if pain, redness, swelling, or tenderness occur in the genital or perineal area, along with fever or malaise because, although rare, this cluster of symptoms may become life-threatening.

- Instruct patient that if a dose is missed, to take it as soon as it is remembered unless it is almost time for the next dose. Then patient should skip the missed dose and resume taking drug at the next regularly scheduled time. Warn patient never to double a dose to make up for a missed dose.

## daptomycin

### Cubicin, Cubicin RF

## Class and Category

*Pharmacologic class:* Cyclic lipopeptide

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat complicated skin and skin structure infections caused by Staphylococcus aureus (including methicillin-resistant isolates), Streptococcus agalactiae, S. dysgalactiae subspecies Enterococcus faecalis (vancomycin-susceptible isolates only) and equisimilis, S. pyogenes*

### **I.V. INFUSION, I.V. INJECTION (CUBICIN, CUBICIN RF)**

**Adults.** 4 mg/kg administered over 2 min as an I.V. injection or over 30 min as an I.V. infusion once daily for 7 to 14 days.

### **I.V. INFUSION (CUBICIN, CUBICIN RF)**

**Children ages 12 to 17.** 5 mg/kg once every 24 hr infused over 30 min and given for up to 14 days.

**Children ages 7 to 11.** 7 mg/kg once every 24 hr infused over 30 min and given for up to 14 days.

**Children ages 2 to 6.** 9 mg/kg every 24 hr infused over 60 min and given for up to 14 days.

**Children ages 1 to less than 2 years.** 10 mg/kg once every 24 hr infused over 60 min and given for up to 14 days.

- *To treat Staphylococcus aureus bloodstream infections (bacteremia), including right-sided infective endocarditis, caused by methicillin-susceptible and methicillin-resistant isolates*

### **I.V. INFUSION, I.V. INJECTION**

**Adults.** 6 mg/kg administered over 2 min as an I.V. injection or over 30 min as an I.V. infusion once daily for 2

to 6 wk.

- *To treat pediatric patients with S. aureus bloodstream infections (bacteremia)*

## **I.V. INFUSION (CUBICIN)**

**Children ages 12 to 17.** 7 mg/kg infused over 30 min once daily for up to 42 days.

**Children ages 7 to 11.** 9 mg/kg infused over 30 min once daily for up to 42 days.

**Children ages 1 to 6.** 12 mg/kg infused over 60 min once daily for up to 42 days.

**DOSAGE ADJUSTMENT** For adult patients with creatinine clearance less than 30 ml/min, dosage is 4 mg/kg every 48 hours for complicated skin or skin-structure infections or 6 mg/kg for bacteremia once every 48 hr. No dosage adjustment has been established for children with renal impairment.

## **Mechanism of Action**

Binds to bacterial membranes to cause rapid depolarization of membrane potential. This loss of membrane potential inhibits protein, DNA, and RNA synthesis, which results in bacterial cell death.

## **Incompatibilities**

Don't mix daptomycin with dextrose-containing diluents and with other intravenously administered drugs or infusions.

## **Contraindications**

Hypersensitivity to daptomycin or its components

# Interactions

## DRUGS

*HMG-CoA reductase inhibitors*: Possibly increased CPK level and increased risk of myopathy

## Adverse Reactions

**CNS:** Anxiety, asthenia, confusion, dizziness, dyskinesia, fatigue, fever, hallucination, headache, insomnia, mental status changes, paresthesia, peripheral neuropathy, rigors, weakness

**CV:** **Atrial fibrillation or flutter, cardiac arrest or failure**, chest pain, hypertension, **hypotension**, peripheral edema, **supraventricular tachycardia**

**EENT:** Blurred vision, dry mouth, eye irritation, gingival pain, hypoesthesia of mouth, pharyngolaryngeal pain, oral candidiasis, sore throat, stomatitis, taste disturbance, tinnitus, visual disturbances

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Abdominal distention or pain, anorexia, ***Clostridium difficile-associated diarrhea***, constipation, diarrhea, dyspepsia, dysphagia, elevated liver enzymes or serum lactate dehydrogenase, **GI hemorrhage**, jaundice, nausea, vomiting

**GU:** **Acute kidney injury, renal failure or insufficiency**; proteinuria; UTI; vaginal candidiasis

**HEME:** Anemia, **decreased platelet count**, eosinophilia, **increased international normalized ratio (INR)**, leukocytosis, **prolonged prothrombin time**, **thrombocythemia, thrombocytopenia**, thrombocytosis

**MS:** Arthralgia, back or limb pain, elevated myoglobin level, muscle cramps or weakness, myalgia, myopathy, osteomyelitis, **rhabdomyolysis**

**RESP:** Cough, dyspnea, **eosinophilic pneumonia**, pleural effusion, pneumonia, shortness of breath

**SKIN:** Acute generalized exanthematous pustulosis, cellulitis, diaphoresis, eczema, erythema, flushing, pruritus, rash, **Stevens-Johnson syndrome**, truncal erythema, urticaria, vesiculobullous rash

**Other:** **Anaphylaxis**, **angioedema**, **bacteremia**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, **electrolyte disturbance**, elevated alkaline phosphatase or creatine phosphokinase levels, **elevated serum sodium bicarbonate level**, fungal infection, **hyperkalemia**, **hypokalemia**, **hypomagnesemia**, injection-site reactions, lymphadenopathy, **sepsis**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cautiously in patients with moderate to severe renal impairment and monitor drug effectiveness closely, as daptomycin may not be as effective in this patient population.
- Obtain blood samples for culture and sensitivity testing before starting daptomycin.
- Reconstitute daptomycin powder (Cubicin formulation) by slowly transferring 10 ml normal saline for injection into vial and pointing needle toward wall of vial to minimize foaming. Then gently rotate vial until all powder is wet. Don't agitate or shake vial. Let vial stand undisturbed for 10 minutes, and then gently rotate or swirl contents for a few minutes, as needed, to obtain a completely reconstituted solution.
- Reconstitute daptomycin powder (Cubicin RF formulation) within the vial with 10 ml of either sterile water for injection or bacteriostatic water for injection using a beveled sterile transfer needle that is 21 gauge or smaller in diameter. Saline-based diluents should not be used because this will result in a hyperosmotic solution that may cause infusion-site reactions if the reconstituted product is administered as an intravenous injection. Rotate or swirl vial contents for a few minutes, as needed, to obtain a completely reconstituted solution.
- Administer as an I.V. injection over a period of 2 minutes. If the drug is to be administered as an I.V. infusion, further dilute either formulation of reconstituted daptomycin solution with normal saline for injection, and administer over 30 minutes for adults and children age 7 and older and 60 minutes for children 6 and under. Reconstituted drug is stable in infusion bag for 12 hours at room temperature or 48 hours refrigerated. Do not infuse with the ReadyMED elastomeric infusion pumps, as daptomycin is not as stable when stored in these pumps.
- Monitor results of the patient's bleeding studies, as ordered. Daptomycin may cause a significant false increase in PT and INR with some brands of laboratory assays. If this occurs during daptomycin therapy, draw blood sample just before next daptomycin dose and evaluate other causes of the increase.
- Monitor patient closely for diarrhea, which may herald pseudomembranous colitis caused by *C. difficile*. If diarrhea occurs, notify prescriber. If pseudomembranous colitis develops, expect to discontinue drug and give fluids, electrolytes, protein, and antibiotic effective against *C. difficile*.
- Monitor patient for evidence of superinfection, and inform prescriber if present. Expect to stop drug and provide care.
- Assess patient for muscle pain or weakness, especially of distal limbs. Expect to monitor creatine phosphokinase (CPK) level weekly or more

often in patients recently or currently taking an HMG-CoA reductase inhibitor. Expect to stop daptomycin, as ordered, if patient has myopathy or marked rise in CPK level.

- Monitor patient's BUN and serum creatinine levels and patient's response to drug closely, especially if renal insufficiency is already present because daptomycin may not be as effective in the presence of renal insufficiency.
- Expect to discontinue daptomycin therapy immediately if patient develops signs and symptoms of eosinophilic pneumonia, such as dyspnea with hypoxic respiratory insufficiency and diffuse pulmonary infiltrates or fever, and prepare to administer systemic steroids, as ordered.

## PATIENT TEACHING

- Inform patient that diarrhea may occur 2 months or more after daptomycin therapy stops. If severe or prolonged, advise patient to notify prescriber as soon as possible; additional treatment may be needed.
- Urge patient to report muscle pain, tenderness, or weakness, and other symptoms of myopathy immediately.
- Instruct patient to notify prescriber immediately if skin reactions occur, because drug may need to be discontinued.

## darbepoetin alfa

**Aranesp**

## Class and Category

*Pharmacologic class:* Recombinant human erythropoietin

*Therapeutic class:* Antianemic

## Indications and Dosages

- *To treat anemia from chronic renal failure*

## **I.V. OR SUBCUTANEOUS INJECTION**

### **Adults on dialysis other than hemodialysis.**

*Initial:* 0.45 mcg/kg as a single dose every wk.

Alternatively, 0.75 mcg/kg once every 2 wk. *Maintenance:*

Dosage individualized and increased monthly to maintain a hemoglobin level not to exceed 11 g/dl.

**Adults not on dialysis.** *Initial:* 0.45 mcg/kg as a single dose every 4 wk, as needed.

**Children age 1 month and over on dialysis.** 0.45 mcg/kg once every wk.

**Children age 1 month and over not on dialysis.** 0.45 mcg/kg once every wk. Alternatively, 0.75 mcg/kg once every 2 wk.

## **I.V. INJECTION**

**Adults on hemodialysis.** *Initial:* 0.45 mcg/kg as a single dose every wk. *Alternatively,* 0.75 mcg/kg once every 2 wk. *Maintenance:* Dosage individualized and increased monthly to maintain a hemoglobin level not to exceed 11 g/dl.

**DOSAGE ADJUSTMENT** Dosage reduced or therapy interrupted if hemoglobin level increases and approaches 12 g/dl for children, 11 g/dl for adults on dialysis, and 10 g/dl for adults not on dialysis. Dosage reduced by about 25% if hemoglobin level increases by more than 1 g/dl in a 2-wk period. Dosage increased by about 25% of previous dose if hemoglobin level increases less than 1 g/dl over 4 wk but only if serum ferritin level is 100 mcg/L or greater and serum transferrin saturation is 20% or greater. Further increases made at 4-wk intervals until specified hemoglobin level is obtained.

**DOSAGE ADJUSTMENT** For conversion from epoetin alfa to darbepoetin alfa, dosage administered every wk for patient who previously received epoetin alfa 2 to 3 times/wk and once every 2 wk for patient who previously received

epoetin alfa once/wk. For conversion from epoetin alfa, 6.25 mcg/wk darbepoetin alfa given every wk for adult patients who received less than 1,500 units/wk of epoetin alfa; 6.25 mcg/week darbepoetin alfa given every wk for adult and pediatric patients who received 1,500 to 2,499 units/wk of epoetin alfa; 12.5 mcg/wk (10 mcg/wk for children) darbepoetin alfa every wk for patients who received 2,500 to 4,999 units/wk of epoetin alfa; 25 mcg/wk (20 mcg/wk for children) darbepoetin alfa every wk for adult and pediatric patients who received 5,000 to 10,999 units/wk of epoetin alfa; 40 mcg/wk darbepoetin alfa every wk for adult and pediatric patients who received 11,000 to 17,999 units/wk of epoetin alfa; 60 mcg/wk darbepoetin alfa every wk for adult and pediatric patients who received 18,000 to 33,999 units/wk of epoetin alfa; 100 mcg/wk darbepoetin alfa every wk for adult and pediatric patients who received 34,000 to 89,999 units/wk of epoetin alfa; 200 mcg/wk darbepoetin alfa every wk for adult and pediatric patients who received 90,000 or more units/wk of epoetin alfa.

- *To treat chemotherapy-induced anemia in patients with nonmyeloid malignancies and hemoglobin level less than 10 g/dl and if there is a minimum of 2 additional months of planned chemotherapy*

## **SUBCUTANEOUS INJECTION**

**Adults.** *Initial:* 2.25 mcg/kg as a single dose every wk until completion of a chemotherapy course. Alternatively, 500 mcg every 3 wk until completion of a chemotherapy course. *Maintenance:* Dosage individualized to maintain a target hemoglobin level.

***DOSAGE ADJUSTMENT*** Dosage increased to 4.5 mcg/kg/wk (no dosage adjustment if patient is already receiving 500 mcg every 3 wk) if hemoglobin level increases less than 1.0 g/dl after 6 wk of therapy. If it increases more than 1.0 g/dl

over 2 wk, dosage reduced by about 40%. If hemoglobin level exceeds a level needed to avoid RBC transfusion, dose withheld until hemoglobin approaches level when RBC transfusion may be required. Then, therapy is restarted at a dose about 40% less than last dose given.

Route	Onset	Peak	Duration
I.V., SubQ	2-6 wk	Unknown	Unknown

## Mechanism of Action

Stimulates release of reticulocytes from the bone marrow into the bloodstream, where they develop into mature RBCs.

## Incompatibilities

Don't mix darbepoetin alfa with any other drug.

## Contraindications

History of pure red cell aplasia that began after treatment with darbepoetin alfa or other erythropoietin protein drugs, hypersensitivity to darbepoetin alfa or its components, uncontrolled hypertension

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Asthenia, **CVA**, dizziness, fatigue, fever, headache, **seizures**, transient ischemic attack

**CV:** **Acute MI**, angina, **arrhythmias**, **cardiac arrest or death**, chest pain, **congestive heart failure**, edema, hypertension, **hypotension**, peripheral edema, vascular access thrombosis, **thromboembolic events**

**GI:** Abdominal pain, constipation, diarrhea, nausea, vomiting

**HEME:** **Low reticulocyte count**, **pure red cell aplasia**, **severe anemia**

**MS:** Arthralgia, back pain, limb pain, muscle spasm, myalgia

**RESP:** Bronchitis, **bronchospasm**, cough, dyspnea, pneumonia, **pulmonary embolism**, upper respiratory tract infection

**SKIN:** **Erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, dehydration, infection, flu-like symptoms, injection-site pain, **sepsis**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that before starting darbepoetin alfa therapy, expect to correct folic acid or vitamin B<sub>12</sub> deficiencies because these conditions may interfere with drug's effectiveness.
- Ensure that patient has received the medication guide and patient instructions for darbepoetin alfa and that a written acknowledgment of a discussion of the risks involved with this type of therapy has been obtained before first dose is given.
- Be aware that darbepoetin alfa shouldn't be given to cancer patients when a cure is anticipated because drug may decrease survival rate and increase tumor progression in patients with certain types of cancers, such as breast, cervical, head and neck, lymphoid, and non-small-cell lung cancers. Be aware that all prescribers and hospitals must enroll in and comply with the ESA APPRISE oncology program to be able to prescribe and dispense the drug.
- Use extreme caution with darbepoetin alfa therapy in patients undergoing coronary artery bypass graft surgery because of increased risk of death, and in patients undergoing orthopedic procedures because of increased risk of deep venous thrombosis.
- Be aware that to ensure effective drug response, expect to obtain serum ferritin level and transferrin saturation before and during therapy, as ordered. If serum ferritin level is less than 100 mcg/L or serum transferrin saturation is less than 20%, expect to begin supplemental iron therapy.
- Don't shake vial during preparation to avoid denaturing drug and rendering it biologically inactive.
- Discard drug if discoloration or particulate matter is present.
- Don't dilute drug before giving it.
- Know that needle cover on prefilled syringe contains dry natural rubber and may cause allergic reaction in those with latex sensitivity.
- Discard unused portion of drug because it contains no preservatives.
- Monitor patient closely for hypertension during therapy. Expect to reduce dosage or withhold drug if blood pressure is poorly controlled with

antihypertensive and dietary measures.

- Monitor hemoglobin level weekly, as ordered, until hemoglobin stabilizes and maintenance dosage has been achieved. Then monitor hemoglobin level regularly, as ordered. After each dosage adjustment, expect to check hemoglobin level weekly for 4 weeks until it stabilizes in response to dosage change.

**WARNING** Know that if hemoglobin level increases more than about 1 g/dl during any 2-week period or it exceeds 12 g/dl for children, 11 g/dl for adult patient on dialysis, 10 g/dl for adult patient not on dialysis, or target range for cancer patient, the risk of acute MI, cardiac arrest, congestive heart failure, fluid overload with peripheral edema, seizures, shortened survival, stroke, tumor progression, vascular infarction, vascular ischemia, vascular thrombosis, and worsened hypertension increases. Expect to decrease dosage if this occurs.

- Expect to discontinue darbepoetin in cancer patients if hemoglobin level hasn't increased after 8 weeks or if patient continues to need transfusions despite therapy.
- Institute seizure precautions according to facility policy.
- Monitor patient for severe skin reactions that may include blistering and skin exfoliation. Notify prescriber immediately, if noted, and expect darbepoetin therapy to be discontinued. Prepare to provide supportive care, as ordered.
- Monitor renal function test results and fluid and electrolyte balance for signs of declining renal function in patients with renal impairment. If patient starts dialysis, monitor hemoglobin and blood pressure closely and expect dosage and route of administration to be adjusted, as needed, for type of dialysis.
- Store drug at 2° to 8° C (36° to 46° F). Don't freeze, and do protect from light.

## **PATIENT TEACHING**

- Instruct patient how to administer a subcutaneous injection, rotate sites, and properly dispose of needles, syringes, or unused portions of single-

dose vials.

- Advise patient that the risk of seizures is highest during the first 90 days of therapy. Discourage her from engaging in hazardous activities during this time.
- Emphasize the importance of complying with the dosage regimen and keeping follow-up medical and laboratory appointments.
- Advise patient to follow up with her prescriber for blood pressure monitoring.
- Encourage patient to eat adequate quantities of iron-rich foods.
- Teach patient and her caregiver the proper administration technique if darbepoetin alpha will be administered at home.
- Caution patient and her caregiver not to reuse needles, syringes, or drug product. Thoroughly instruct them in proper needle and syringe disposal using a puncture-resistant container.
- Explain that needle cover on prefilled syringe contains dry natural rubber and may cause allergic reaction in those with latex sensitivity.
- Review possible adverse reactions, and urge patient to notify prescriber if she experiences chest pain, headache, rash, seizures, shortness of breath, or swelling.

## darifenacin

### **Enablex**

## **Class and Category**

*Pharmacologic class:* Anticholinergic

*Therapeutic class:* Bladder antispasmodic

## **Indications and Dosages**

- *To treat overactive bladder with symptoms of frequency, urge incontinence, or urgency*

## E.R. TABLETS

**Adults.** *Initial:* 7.5 mg daily, increased to 15 mg daily after 2 wk as needed.

**DOSAGE ADJUSTMENT** For patients with moderate hepatic impairment and those taking potent CYP3A4 inhibitors (such as clarithromycin, itraconazole, ketoconazole, nefazodone, nelfinavir, and ritonavir) daily dosage should not exceed 7.5 mg.

Route	Onset	Peak	Duration
P.O.	Unknown	7 hr	Unknown

## Mechanism of Action

Antagonizes effect of acetylcholine on muscarinic receptors in detrusor muscle, decreasing muscle spasms that cause inappropriate bladder emptying. This action increases bladder capacity and volume, which relieves sensations of frequency and urgency and enhances bladder control.

## Contraindications

Gastric retention, hypersensitivity to darifenacin or its components, uncontrolled narrow-angle glaucoma, urinary retention, and patients at risk for these conditions

## Interactions

### DRUGS

*CYP2D6 substrates such as flecainide, thioridazine, tricyclic antidepressants: Risk of toxicity with these drugs*  
*potent CYP3A4 inhibitors (such as clarithromycin, itraconazole, ketoconazole, nefazodone, nelfinavir, and ritonavir): Decreased metabolism and increased effects of darifenacin, possibly increasing the risk of adverse reactions*

*other anticholinergics: Increased frequency and severity of anticholinergic adverse reactions*

## **Adverse Reactions**

**CNS:** Asthenia, confusion, dizziness, hallucinations, headache, somnolence

**CV:** Hypertension, palpitations, peripheral edema

**EENT:** Abnormal vision, dry eyes or mouth, pharyngitis, rhinitis, sinusitis

**GI:** Abdominal pain, constipation, diarrhea, indigestion, nausea, vomiting

**GU:** Urine retention, UTI, vaginitis

**MS:** Arthralgia, back pain

**RESP:** **Airway obstruction**, bronchitis

**SKIN:** Dry skin, **erythema multiforme**, interstitial granuloma annulare, pruritus, rash

**Other:** **Anaphylaxis**, **angioedema**, flu-like symptoms, **hypersensitivity reactions**, weight gain

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use darifenacin cautiously in patients with significant bladder outflow obstruction; they have increased risk of urine retention. Also use cautiously in patients with controlled narrow-angle glaucoma, as darifenacin therapy may worsen this condition.
- Use darifenacin cautiously in patients with myasthenia gravis, severe constipation, or ulcerative colitis, because it may decrease GI motility. Also use drug cautiously in obstructive GI disorders because it increases the risk of gastric retention.
- Monitor patient for signs of anticholinergic CNS effects such as confusion, hallucinations, headache, and somnolence, especially at beginning of therapy and with dosage increases.

**WARNING** Monitor patient closely for serious adverse reactions that may become life-threatening, such as anaphylaxis and angioedema of the face, larynx, lips, and/or tongue that may occur even after just one dose. If present, withhold drug, notify prescriber immediately, and provide emergency supportive care, as indicated.

## PATIENT TEACHING

- Tell patient to swallow tablets with liquid and not to break, crush, or split them.

- Advise patient to avoid exercising in hot weather because darifenacin decreases sweating, increasing the risk of heatstroke.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Warn patient to seek immediate medical attention if he experiences any signs of a serious drug reaction, including swelling of his face, lips, throat, and/or tongue.

## deferoxamine mesylate

### Desferal

## Class and Category

*Pharmacologic class:* Iron chelator

*Therapeutic class:* Heavy metal chelator

## Indications and Dosages

➤ *To treat acute iron intoxication*

### I.M. INJECTION

**Adults and children age 3 and over who are not in shock.** *Initial:* 1,000 mg, followed by 500 mg every 4 hr for 2 doses, if needed. Additional doses of 500 mg may be administered every 4 to 12 hr, as needed. *Maximum:* 6,000 mg in 24 hr.

### I.V. INFUSION

**Adults and children age 3 and over who are in shock.** *Initial:* 1,000 mg administered at a rate not to exceed 15

mg/kg/hr, followed by 500 mg administered at a rate not to exceed 125 mg/hr every 4 hr for 2 doses, if needed.

Additional doses of 500 mg may be administered at a rate not to exceed 125 mg/hr every 4 to 12 hr, as needed.

*Maximum:* 6,000 mg in 24 hr.

- *To treat chronic iron overload due to transfusion-dependent anemias*

## **I.M. INJECTION**

**Adults and children age 3 and over.** 500 to 1,000 mg daily. *Maximum:* 1,000 mg daily.

## **I.V. INFUSION**

**Adults.** 40 to 50 mg/kg/day infused at a rate no greater than 15 mg/kg/hr and given over 8 to 12 hr for 5 to 7 days per week. *Maximum:* 60 mg/kg/day.

**Children age 3 and over.** 20 to 40 mg/kg/day infused at a rate no greater than 15 mg/kg/hr and given over 8 to 12 hr. *Maximum:* 40 mg/kg/day.

## **SUBCUTANEOUS INFUSION**

**Adults and children age 3 and over.** 20 to 40 mg/kg/day (1,000 to 2,000 mg/day) administered over 8 to 24 hr.

## **Mechanism of Action**

Binds iron by forming a stable complex with it. This prevents iron from entering into further chemical reactions. The chelate then passes through the kidneys and out of the body in urine, thereby decreasing the iron level in the body.

## **Contraindications**

Anuria, hypersensitivity to deferoxamine or its components, severe renal disease

## Interactions

### DRUGS

*prochlorperazine*: Possibly impaired consciousness

*vitamin C*: Increased availability of iron for chelation by deferoxamine

## Adverse Reactions

**CNS:** Dizziness, **exacerbation or precipitation of aluminum-related dialysis encephalopathy**, fever, headache, paresthesias, peripheral neuropathy, **seizures**

**CV:** **Hypotension**, **shock**, tachycardia

**EENT:** Blurred vision, cataracts, decreased acuity, dyschromatopsia, high-frequency sensorineural hearing loss, loss of vision, night blindness, optic neuritis, retinopathy, scotoma, tinnitus, visual field defects

**GI:** Abdominal discomfort, diarrhea, **hepatic dysfunction**, increased liver enzymes, nausea, vomiting

**GU:** **Acute renal failure**, dysuria, increased serum creatinine, renal tubular disorder

**HEME:** **Leukopenia**, **thrombocytopenia**

**MS:** Arthralgia, growth retardation, metaphyseal dysplasia, myalgia

**RESP:** **Acute respiratory distress syndrome**, **asthma**

**SKIN:** Rash, urticaria

**Other:** **Anaphylaxis; angioedema**; infections with *Yersinia* or *Mucormycosis*; injection-site reactions such as localized irritation, pain, burning, swelling, induration, infiltration, pruritus, erythema, wheal formation, eschar, crust, vesicles, or local edema

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Expect to administer other supportive measures, as ordered, when treating acute iron intoxication with deferoxamine because acute respiratory distress syndrome may occur. Supportive measures include control of shock with blood transfusions, intravenous fluids, oxygen, and vasopressors; correction of acidosis; gastric lavage; induction of emesis with syrup of ipecac; and suction and maintenance of a clear airway.
- Know that patients with thalassemia inadvertently given a high dose or rapid intravenous infusion of deferoxamine may develop acute respiratory distress syndrome and other life-threatening disorders such as hypotension, CNS depression, and acute renal failure. Symptomatic treatment is required, as there is no specific antidote for deferoxamine, although the drug is readily dialyzable.
- Reconstitute drug according to how the drug will be administered. For intramuscular administration, add 2 ml of diluent (sterile water for injection) to a 500-mg vial or 8 ml of diluent to a 2-g vial. For intravenous

or subcutaneous administration, add 5 ml of diluent (sterile water for injection) to a 500-mg vial or 20 ml of diluent to a 2-g vial. Make sure drug is completely dissolved before the solution is withdrawn. Discard unused portion.

- Further dilute reconstituted solution with normal or half normal saline, glucose in water, or Ringer's lactate solution if drug will be administered intravenously.
- Follow infusion rates exactly as ordered when drug is administered intravenously because flushing, urticaria, hypotension, and shock have occurred in a few patients when deferoxamine was administered by rapid intravenous injection.
- Use a portable pump capable of providing continuous mini-infusion when administering drug by subcutaneous infusion. Be aware that the duration of infusion must be individualized as some patients excrete more iron after a short infusion of 8 to 12 hours, while another patient may need a 24-hour infusion to excrete the same amount.
- Monitor patient closely for changes in hearing or vision, especially in patients receiving deferoxamine at high doses or over prolonged periods of time, or in patients who have low ferritin levels. If present, notify prescriber immediately and expect drug to be discontinued. Expect audiometry, fundoscopy, slit-lamp examinations, and visual acuity tests to be performed periodically in patients treated for prolonged periods of time. Early detection improves the possibility of reversal of these symptoms or test abnormalities.
- Monitor patient's serum creatinine level, and assess patient for symptoms of renal dysfunction, because deferoxamine has been associated with renal dysfunction.
- Assess children regularly for growth retardation, especially if high doses of the drug are being administered in the presence of low ferritin levels. Monitor the child's body weight and growth every 3 months. If abnormalities are detected, notify the prescriber because growth velocity may partially resume to pretreatment rates after a reduction of deferoxamine dosage occurs.
- Monitor patient, especially children, closely for signs and symptoms of respiratory distress, especially following treatment with excessively high intravenous doses of deferoxamine.

**WARNING** Assess patient regularly for infections because either deferoxamine therapy or iron overload may enhance susceptibility to generalized infections. Some cases of mucormycosis have been fatal. If signs and

symptoms occur, notify prescriber immediately and expect drug to be discontinued and appropriate treatment instituted.

- Expect to administer vitamin C with deferoxamine therapy because iron overload usually causes a vitamin C deficiency. However, be aware that high doses (more than 500 mg daily in adults, 100 mg in children age 10 and older, and 50 mg in children under age 10) may cause cardiac dysfunction. Therefore, make sure patient is not receiving vitamin C if he has cardiac failure, expect supplemental vitamin C therapy to begin only after an initial month of regular treatment with deferoxamine, and make sure the daily dose of vitamin C does not exceed 200 mg in adults, given in divided doses. Monitor all patients receiving deferoxamine and vitamin C therapy concomitantly for cardiac dysfunction and report any dysfunction immediately to prescriber.
- Be aware that patients with aluminum-related encephalopathy who are receiving dialysis may develop seizures as a result of deferoxamine therapy. Deferoxamine therapy may also precipitate the onset of dialysis dementia in these patients, as well as cause a decrease in the patient's serum calcium levels and aggravate hyperparathyroidism, if present.
- Discontinue deferoxamine therapy, as ordered, 48 hours prior to scintigraphy because imaging results may be distorted as a result of the rapid urinary excretion of deferoxamine-bound gallium-67.

## **PATIENT TEACHING**

- Inform patient that deferoxamine therapy is an adjunct to, and not a substitute for, standard measures used to treat acute iron intoxication.
- Advise patient not to exceed the recommended dose of daily vitamin C therapy prescribed.
- Caution patient not to perform hazardous activities such as driving until CNS, visual, and auditory adverse effects are known.
- Inform patient that his urine may have a reddish discoloration because of deferoxamine therapy.

**delafloxacin**

# Baxdela

## Class and Category

*Pharmacologic class:* Fluoroquinolone

*Therapeutic class:* Antibacterial

## Indications and Dosages

- *To treat acute bacterial skin and skin structure infections (ABSSSI) caused by gram-negative organisms (Enterobacter cloacae, Escherichia coli, Klebsiella pneumoniae, Pseudomonas aeruginosa) and gram-positive organisms (Enterococcus faecalis, Staphylococcus aureus, S. haemolyticus, S. lugdunensis, Streptococcus agalactiae, S. anginosus, S. pyogenes); to treat community-acquired bacterial pneumonia (CABP) caused by Chlamydia pneumoniae, E. coli, Haemophilus influenzae, H. parainfluenzae, K. pneumoniae, Legionella pneumophila, Mycoplasma pneumoniae, P. aeruginosa, S. aureus, and S. pneumoniae*

## **TABLETS**

**Adults.** 450 mg every 12 hr for 5 to 10 days (CABP) or 5 to 14 days (ABSSSI).

## **I.V. INFUSION**

**Adults.** 300 mg every 12 hr over 60 min for 5 to 10 days (CABP) and 5 to 14 days (ABSSSI). Alternatively, 300 mg every 12 hr by I.V. infusion over 60 min, switched to 450

mg orally every 12 hr at the discretion of the prescriber for 5 to 10 days (CABP) and 5 to 14 days (ABSSSI).

**DOSAGE ADJUSTMENT** For patients with an estimated glomerular filtration rate (eGFR) between 15 and 29 ml/min who are receiving the drug intravenously, dosage reduced to 200 mg every 12 hr or dosage reduced to 200 mg every 12 hr, then switched to 450 mg orally every 12 hr at the discretion of the prescriber.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	Unknown
I.V.	Unknown	Unknown	Unknown

## Mechanism of Action

Inhibits both bacterial topoisomerase IV and DNA gyrase enzymes, which are required for bacterial DNA recombination, repair, replication, and transcription.

## Incompatibilities

Do not administer with other additives, medications, or substances other than 0.9% sodium chloride injection or D5W because incompatibilities are unknown.

## Contraindications

Hypersensitivity to delafloxacin, other fluoroquinolones, or any of its components

## Interactions

### DRUGS

*antacids containing aluminum or magnesium, didanosine, iron preparations, multivitamins containing iron or zinc, sucralfate*: Significantly decreased absorption of oral delafloxacin

## Adverse Reactions

**CNS:** Abnormal dreams, agitation, anxiety, confusion, delirium, depression, disorientation, disturbances in attention, dizziness, hallucinations, headache, hypoesthesia, **increased intracranial pressure**, insomnia, memory impairment, nervousness, nightmares, paresthesia, paranoia, peripheral neuropathy, **seizures, suicidal ideation**, syncope, tremors, toxic psychosis, vertigo

**CV:** **Aortic aneurysm and dissection, bradycardia**, hypertension, **hypotension**, palpitations, phlebitis, tachycardia, **ventricular extrasystoles**

**EENT:** Blurred vision, oral candidiasis, taste alteration, tinnitus

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Abdominal pain, **Clostridium difficile-associated diarrhea**, diarrhea, dyspepsia, elevated liver enzymes, nausea, vomiting

**GU:** Elevated blood creatinine levels, **renal failure**, renal impairment, vulvovaginal candidiasis

**HEME:** **Agranulocytosis**, anemia, **leukopenia, neutropenia, pancytopenia**

**MS:** Myalgia, tendinitis, tendon rupture

**RESP:** Dyspnea

**SKIN:** Dermatitis, flushing, pruritus, rash, urticaria

**Other:** Anaphylaxis, angioedema, elevated alkaline phosphatase and creatine phosphokinase levels, fungal infection, infusion-site reactions (bruising, discomfort, edema, erythema, irritation, pain, phlebitis, swelling, thrombosis)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that fluoroquinolones, including delafloxacin, may exacerbate muscle weakness in patients with myasthenia gravis and should not be given to patients with a history of myasthenia gravis.
- Be aware that studies have shown an increased risk for aortic aneurysm and dissection within two months following use of fluoroquinolones, especially in elderly patients. Drug should only be given to patients with an aortic aneurysm or who are at greater risk for an aortic aneurysm if there are no alternative antibacterial treatment.
- Administer delafloxacin tablets at least 2 hours before or 6 hours after antacids containing aluminum or magnesium, didanosine, iron preparations, multivitamins containing iron or zinc, or sucralfate, because absorption is affected by these drugs.
- Reconstitute powder for intravenous administration by using 10.5 ml of 0.9% sodium chloride injection or 5% Dextrose Injection (D5W) for each 300-mg vial. Shake the vial vigorously until contents are completely

dissolved. The reconstituted vial will contain 300 mg per 12 ml of clear yellow to amber-colored solution. Further dilute to a total volume of 250 ml, using either 0.9% Sodium Chloride or D5W to achieve a concentration of 1.2 mg/ml. To do so, withdraw 12 ml for a 300-mg dose and 8 ml for a 200-mg dose from the vial and transfer to an intravenous bag to achieve a 250-ml volume of infusion solution. Discard any unused portion of the reconstituted solution. Reconstituted vials or diluted solution already added to an intravenous bag may be stored either in the refrigerator or at room temperature for up to 24 hours. The solution should not be frozen.

- Administer delafloxacin intravenously over 60 minutes. If a common intravenous line is being used to administer other drugs in addition to delafloxacin, the line should be flushed before and after each delafloxacin infusion with 0.9% sodium chloride injection or D5W.

**WARNING** Know that fluoroquinolones like delafloxacin have been associated with disabling and potentially irreversible serious adverse reactions that have occurred together, including central nervous system effects, peripheral neuropathy, tendinitis, and tendon rupture. Fluoroquinolones also have been associated with an increased risk of increased intracranial pressure and seizures. At the first sign or symptom of any serious adverse reaction, withhold delafloxacin and notify prescriber. Expect delafloxacin to be discontinued.

- Monitor patients with severe renal impairment receiving intravenous delafloxacin by obtaining serum creatinine levels and eGFR values, as ordered. Know that if serum creatinine level increases, prescriber should be notified; expect patient to be switched to oral form. Notify prescriber if patient's eGFR decreases to less than 15 ml/min and expect drug to be discontinued.
- Assess patient for evidence of peripheral neuropathy. Notify prescriber and expect to stop drug if patient complains of burning, numbness, pain, tingling, or weakness in extremities or if physical examination reveals deficits in light touch, motor strength, pain, position sense, temperature, or vibratory sensation.
- Monitor patients (especially patients over 60 years of age, patients receiving corticosteroids, and patients who have renal failure or who have had a heart, kidney, or lung transplant) for evidence of tendon rupture, such as inflammation, pain, and swelling at the site. Be aware that tendon

rupture may occur within the first 48 hours of therapy, throughout therapy, or months after delafloxacin therapy. Notify prescriber about suspected tendon rupture, and have patient rest and refrain from exercise until tendon rupture has been ruled out. If present, expect to provide supportive care, as ordered.

- Monitor patient closely for changes in behavior or mood that may be caused by delafloxacin-induced depression or worsening psychotic reactions potentially resulting in self-injurious behavior, such as suicide. Be aware that these reactions may occur even after just one dose. Notify prescriber immediately and expect to discontinue delafloxacin therapy, if present, and institute precautions to keep patient safe until adverse effects have disappeared.
- Assess patient routinely for signs of rash or other hypersensitivity reactions, even after patient has received multiple doses. Stop drug at first sign of rash or other sign of hypersensitivity, and notify prescriber immediately. Be prepared to provide supportive emergency care.
- Monitor patient closely for diarrhea, which may reflect pseudomembranous colitis caused by *Clostridium difficile* infection. If it occurs, notify prescriber and expect to withhold drug and treat diarrhea.
- Monitor patient's blood glucose levels, especially in diabetic patients, and for signs and symptoms of changes in blood glucose levels. Both symptomatic hyperglycemia and hypoglycemia may occur as a result of delafloxacin therapy. If present, alert prescriber and initiate appropriate treatment, as prescribed. Also be aware that severe hypoglycemia has occurred with other fluoroquinolones. If a hypoglycemic reaction occurs, discontinue administration immediately and initiate appropriate treatment for hypoglycemia.

## PATIENT TEACHING

- Urge patient to complete the prescribed course of therapy, even if he feels better before it's finished.
- Tell patient that if he misses a dose, he should take it as soon as possible anytime up to 8 hours prior to the next dose. If less than 8 hours remain before the next dose, he should wait until the next scheduled dose.
- Instruct patient to take tablets at least 2 hours before or 6 hours after antacids containing aluminum or magnesium, didanosine, iron preparations, multivitamins containing iron or zinc, or sucralfate.
- Urge patient to avoid hazardous activities until CNS effects of drug are known.

- Advise patient to notify prescriber about changes in limb movement or sensation and about inflammation, pain, or swelling over a joint. Urge patient to rest the affected limb at the first sign of discomfort.
- Tell patient to stop taking drug and to notify prescriber at first sign of rash or other hypersensitivity reaction.
- Urge patient to report bloody, watery stools to prescriber immediately, even up to 2 months after drug therapy has ended.
- Urge caregivers to monitor patient closely for suicidal tendencies if patient develops depression or worsening of psychotic behavior during therapy and to notify prescriber.
- Instruct patient to report any persistent, severe, or unusual signs and symptoms to prescriber.
- Warn patients, especially diabetics, that delafloxacin may alter blood glucose levels. Review signs and symptoms of hyperglycemia and hypoglycemia. Tell patient to immediately report symptomatic changes in blood glucose levels to prescriber and review how to treat hypoglycemia.

## denosumab

**Prolia, Xgeva**

### Class and Category

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* Antiresorptive, antiosteoporotic

### Indications and Dosages

- *To treat men and postmenopausal women with osteoporosis at high risk for fracture; to treat bone loss in men receiving androgen deprivation therapy for nonmetastatic prostate cancer; to treat bone loss in*

*women receiving adjuvant aromatase inhibitor therapy for breast cancer; to treat glucocorticoid-induced osteoporosis in men and women at high risk of fracture who are either initiating or continuing systemic glucocorticoids in a daily dosage equivalent to 7.5 mg or greater of prednisone and expected to remain on glucocorticoids for at least 6 months*

## **SUBCUTANEOUS INJECTION (PROLIA)**

**Adult.** 60 mg once every 6 months.

- *To prevent skeletal-related events in patients with multiple myeloma and in patients with bone metastasis from solid tumors*

## **SUBCUTANEOUS INJECTION (XGEVA)**

**Adult.** 120 mg every 4 wk.

- *To treat giant cell tumor of bone; to treat hypercalcemia of malignancy refractory to bisphosphonate therapy*

## **SUBCUTANEOUS INJECTION (XGEVA)**

**Adult.** 120 mg every 4 wk with additional 120 mg doses on days 8 and 15 of the first month of therapy.

Route	Onset	Peak	Duration
SubQ	Unknown	10 days	Unknown

## **Mechanism of Action**

Binds to RANKL, a transmembrane or soluble protein required for the formation, function, and survival of osteoclasts, the cells responsible for bone resorption. By

preventing RANKL from activating its receptor, RANK, on the surface of osteoclasts, osteoclast formation, function, and survival are inhibited. This action decreases bone resorption and increases bone mass and strength in both cortical and trabecular bone.

## Contraindications

Hypersensitivity to denosumab and its components, hypocalcemia, pregnancy

## Interactions

### DRUGS

*other calcium-lowering drugs:* Augmentation of calcium-lowering effect with possible severe hypocalcemia

## Adverse Reactions

**CNS:** Asthenia, headache, insomnia, sciatica, vertigo

**CV:** Angina pectoris, **atrial fibrillation**, **endocarditis**, hypercholesterolemia, peripheral edema

**EENT:** Ear infection, nasopharyngitis

**ENDO:** Increased serum parathyroid hormone levels (presence of severe renal impairment or dialysis)

**GI:** Abdominal pain, constipation, diarrhea, flatulence, gastroesophageal reflux disease, nausea, **pancreatitis**, upper abdominal pain

**GU:** Cystitis, UTI

**HEME:** Anemia, **thrombocytopenia**

**MS:** Arthralgia; atypical subtrochanteric and diaphyseal femoral fractures; back, bone, extremity including joint, or musculoskeletal pain; jaw osteonecrosis; myalgia; spinal osteoarthritis

**RESP:** Pneumonia, upper respiratory infection

**SKIN:** Alopecia, cellulitis, dermatitis, eczema, erysipelas (infection of upper dermis and superficial lymphatics), erythema, lichenoid drug eruptions, pruritus, rash, urticaria

**Other:** Anaphylaxis, angioedema, antibodies to denosumab, herpes zoster, hypercalcemia of malignancy, hypocalcemia, hypophosphatemia, malignancies (breast, gastrointestinal, reproductive), serious infections

## Childbearing Considerations

### PREGNANCY

- Pregnancy status of females who are of childbearing potential should be verified before drug therapy is initiated.
- Drug may cause fetal harm.
- Drug should not be given during pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### REPRODUCTION

- Females who are of childbearing potential should be advised to use effective contraception during therapy, and for at least 5 months after the

last dose of the drug.

## Nursing Considerations

- Know that preexisting hypocalcemia must be corrected prior to denosumab therapy.
- Ensure that a pregnancy test has been performed and is negative for all childbearing women before denosumab therapy is begun, because the drug can be toxic to the fetus.
- Be aware that the drug solution may contain trace amounts of translucent to white proteinaceous particles. However, do not use if the solution is discolored or cloudy, or if the solution contains many particles or foreign particulate matter.
- Do not handle the gray needle cap on the prefilled syringe if allergic to latex.
- Prior to administration, remove drug from refrigerator and bring to room temperature, which generally takes 15 to 30 minutes. Do not warm the drug any other way.
- Know that when preparing to administer drug using the single prefilled syringe, do not slide the green safety guard forward over the needle, as it will lock in place and prevent injection. Do so only after the injection to prevent an accidental needle stick.
- Withdraw solution from a single-use vial using a 27G needle. Also administer the drug using a 27G needle.
- Administer denosumab in the upper arm, thigh, or abdomen.

**WARNING** Monitor patient closely for hypersensitivity reactions that may be severe such as dyspnea, hypotension, lip swelling, pruritus rash, upper airway edema, and urticaria. If present, stop denosumab therapy immediately, notify prescriber, and provide supportive care, as needed and ordered.

**WARNING** Monitor patient's calcium level, as ordered, especially in patients predisposed to hypocalcemia or disturbances of mineral metabolism, such as a history of excision of the small intestine, hypoparathyroidism,

parathyroid or thyroid surgery, malabsorption syndromes, or severe renal impairment. Know that severe hypocalcemia has occurred with denosumab therapy resulting, in some cases, in death. Monitor patient closely for signs and symptoms of hypocalcemia such as neuromuscular irritability, and notify prescriber immediately if present. Expect drug to be discontinued, administer calcium replacement therapy, as ordered, and provide supportive care.

- Be aware that significant hypercalcemia has also occurred in patients with growing skeletons and patients with a giant cell tumor of the bone weeks to months after drug was discontinued. Monitor patient for signs of hypercalcemia (abdominal or bone pain, confusion, constipation, fatigue, frequent urination, muscle weakness, nausea, thirst, vomiting) and if present, notify prescriber and expect to treat, as prescribed.
- Know that fracture risk increases, including the risk of multiple vertebral fractures, when denosumab is discontinued. New vertebral fractures may occur as early as 7 months after the last dose. If denosumab therapy is discontinued, discuss possibility of patient transitioning to an alternative antiresorptive therapy with prescriber.
- Monitor patient for signs and symptoms of infection, because denosumab increases risk, especially if patient is receiving immunosuppressant therapy or has an impaired immune system. Serious skin infections as well as infections of the abdomen, ear, and urinary tract have occurred. There has also been increased incidence of endocarditis in patients receiving denosumab. Notify prescriber if an infection is suspected.

## **PATIENT TEACHING**

- Tell patient that if a dose of denosumab is missed, injection should be administered as soon as convenient. Thereafter, future injections should be scheduled from the date of the actual injection.
- Instruct patient to take a calcium supplement of 1,000 mg and at least 400 international units of vitamin D daily. Review signs and symptoms of hypocalcemia and instruct patient to seek medical care promptly, if present.
- Tell patient to stop taking denosumab and seek immediate emergency care if allergic reactions occur.

- Advise patient to notify prescriber if signs and symptoms of infection occur, such as drainage, fever, pain, redness, or swelling.
- Inform patient to report bone, joint, and/or muscle pain as drug may need to be discontinued depending on the severity.
- Tell patient to notify prescriber if severe adverse skin reactions occur, as drug may need to be discontinued.
- Instruct patient on proper oral hygiene and on the need to notify dentist of denosumab therapy before invasive dental procedures are performed.
- Instruct women of childbearing age to use effective contraception during treatment and for at least 5 months after the last dose of denosumab. Also tell patient to report suspected or confirmed pregnancy immediately, as drug may cause fetal harm and have to be discontinued. Also inform her that breastfeeding is not recommended while taking denosumab.
- Advise patient to report new or unusual groin, hip, or thigh pain or tingling or numbness in fingers and toes.
- Advise patient not to interrupt denosumab therapy without talking with prescriber, because of increased risk for multiple vertebral fractures.
- Advise patients with growing skeletons to report decreased alertness, headache, nausea, or vomiting following discontinuation of drug, as this could indicate a higher than normal calcium level requiring prompt treatment.

## desipramine hydrochloride

### Norpramin

## Class and Category

*Pharmacologic class:* Tricyclic antidepressant

*Therapeutic class:* Antidepressant

## Indications and Dosages

➤ *To treat depression*

## **TABLETS**

**Adults.** *Initial:* 100 to 200 mg daily as single dose or divided doses. Increased gradually to 300 mg daily, if needed. *Maximum:* 300 mg daily.

**Adolescents and elderly patients.** *Initial:* 25 to 50 mg daily in divided doses. Increased gradually, if needed. *Maximum:* 150 mg daily.

Route	Onset	Peak	Duration
P.O.	2-3 wk	Unknown	Unknown

## **Mechanism of Action**

Blocks norepinephrine and serotonin reuptake by adrenergic nerves, which normally release these neurotransmitters from their storage sites when activated by a nerve impulse. By blocking reuptake, this tricyclic antidepressant increases norepinephrine and serotonin levels at nerve synapses, which may elevate mood and reduce depression.

## **Contraindications**

Acute recovery phase of MI; hypersensitivity to desipramine, other tricyclic antidepressants (dibenzazepines), or their components; linezolid or I.V. methylene blue; MAO inhibitor therapy within 14 days

## **Interactions**

## **DRUGS**

*barbiturates, CNS depressants*: Increased CNS depression

*clonidine*: Increased risk of hypertensive crisis

*MAO inhibitors*: Increased risk of life-threatening adverse effects, such as hyperpyretic or hypertensive crisis and severe seizures

*P450 2D6 inhibitors (cimetidine, quinidine), class 1C antiarrhythmics (flecainide, propafenone), many other antidepressants, phenothiazines, selective serotonin reuptake inhibitors*: Increased blood level and adverse effects of desipramine; potential increased blood levels of and adverse reactions to these drugs

*quinolones*: Increased risk of arrhythmias, including torsades de pointes

## **ACTIVITIES**

*alcohol use*: Possibly increased alcohol effects

## **Adverse Reactions**

**CNS**: Agitation, akathisia, anxiety, ataxia, confusion, **CVA**, delusions, disorientation, dizziness, drowsiness, extrapyramidal reactions, fatigue, headache, hypomania, insomnia, lack of coordination, nervousness, nightmares, paresthesia, peripheral neuropathy, psychosis exacerbation, restlessness, **seizures**, **serotonin syndrome**, sleep disturbance, **suicidal ideation**, tremor, weakness

**CV**: **Arrhythmias, including heart block**; hypertension; **hypotension**; palpitations

**EENT**: Acute-angle glaucoma, black tongue, blurred vision, dry mouth, mydriasis, stomatitis, taste perversion, tinnitus

**ENDO**: Breast enlargement and galactorrhea (women), gynecomastia (men), hyperglycemia, **hypoglycemia**,

syndrome of inappropriate ADH secretion

**GI:** Abdominal cramps, anorexia, constipation, diarrhea, elevated liver enzymes, elevated pancreatic enzyme levels, epigastric distress, **hepatitis**, ileus, increased appetite, nausea, vomiting

**GU:** **Acute renal failure**, impotence, libido changes, nocturia, painful ejaculation, testicular swelling, urinary frequency and hesitancy, urine retention

**HEME:** **Agranulocytosis**, eosinophilia, **thrombocytopenia**

**SKIN:** Acne, alopecia, dermatitis, diaphoresis, dry skin, flushing, petechiae, photosensitivity, pruritus, purpura, rash, urticaria

**Other:** **Angioedema**, drug fever, weight gain

## Childbearing Considerations

### PREGNANCY

- pregnancy exposure registry: 1-844-405-6185 or <https://womensmentalhealth.org/clinical-and-researchprograms/pregnancyregistry/antidepressants>
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug maybe present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

# Nursing Considerations

- Use desipramine with extreme caution in patients with cardiovascular disease, glaucoma, seizure disorder, thyroid disease, or urine retention or with a family history of sudden death, cardiac arrhythmias, or conduction disturbances.

**WARNING** Be aware that desipramine increases risk of suicidal ideation in teens; monitor them closely for evidence.

**WARNING** Expect drug to produce sedation and possibly to lower seizure threshold. Take safety and seizure precautions. Seizures may precede arrhythmias and death in some patients. Alert prescriber immediately if seizure activity occurs.

- Monitor blood glucose level often.
- Be prepared to obtain blood sample for leukocyte and differential counts if patient develops fever during therapy.
- Expect to discontinue drug as soon as possible before elective surgery because of its possible adverse cardiovascular effects.

**WARNING** Monitor patient closely for evidence of serotonin syndrome, such as agitation, coma, diarrhea, hallucinations, hyperreflexia, hyperthermia, incoordination, labile blood pressure, nausea, tachycardia, or vomiting. Notify prescriber at once because serotonin syndrome maybe life-threatening. Be prepared to discontinue drug and provide supportive care.

## PATIENT TEACHING

**WARNING** Urge parents to watch teen closely and to report abnormal thinking or behavior, aggression, or hostility.

- Urge patient to use sunscreen outdoors and to avoid sunlamps and tanning beds.
- Instruct patient to notify prescriber immediately about fainting, a fast and pounding heartbeat, restlessness, severe agitation, and strange behavior or thoughts.
- Caution patient not to stop drug abruptly; doing so may cause dizziness, headache, hyperthermia, irritability, malaise, nausea, sleep disturbances, and vomiting.
- Advise against drinking alcohol because of increased risk of adverse CNS reactions.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute-angle glaucoma. Encourage patient to have an eye exam before starting therapy to see if she is at risk.
- Urge diabetic patient to monitor blood glucose level often.

## desmopressin acetate

**DDAVP, Minirin, Nocdurna, Noctiva, Stimate**

### Class and Category

*Pharmacologic class:* Posterior pituitary hormone

*Therapeutic class:* Antidiuretic, hemostatic

### Indications and Dosages

➤ *To manage primary nocturnal enuresis*

## **TABLETS**

**Adults and children age 6 and over.**

*Initial:* 0.2 mg at bedtime, increased as needed. *Maximum:* 0.6 mg daily.

- *To treat nocturia due to nocturnal polyuria in patients who awaken at least 2 times per night to void*

## **NASAL SPRAY (NOCTIVA)**

**Adults younger than 65 years who are not at increased risk for hyponatremia.** 1 spray (1.66 mcg) in either the left or right nostril about 30 min before bedtime.

**Adults 65 years or older and younger adults at risk for hyponatremia.** 1 spray (0.83 mcg) in either the left or right nostril about 30 min before bedtime, increased to 1 spray (1.66 mcg) after 7 days, if needed, provided the serum sodium level is normal.

## **SUBLINGUAL TABLETS (NOC DURNA)**

**Women.** 27.7 mcg once daily, 1 hr before bedtime.

**Men.** 55.3 mcg once daily, 1 hr before bedtime.

- *To control symptoms of central diabetes insipidus*

## **TABLETS**

**Adults and children age 4 and over.**

*Initial:* 0.05 mg twice daily, increased as needed. *Usual:* 0.1 to 1.2 mg in divided doses twice daily or three times daily.

*Maximum:* 1.2 mg daily.

## **I.V. INFUSION, SUBCUTANEOUS INJECTION**

**Adults and adolescents. Usual:** 2 to 4 mcg daily in divided doses twice daily. Dosage adjusted, as needed.

## **NASAL SPRAY (DDAVP)**

**Adults and adolescents.** 10 mcg up to 40 mcg daily as a single dose in one nostril or in divided doses twice daily or three times daily. Dosage adjusted as needed. If daily dose is divided, each dose adjusted separately.

**Children ages 4 to 12 years.** 10 mcg up to 30 mcg daily as a single dose in one nostril or in divided doses twice daily with 30 mcg dose given as 20 mcg in the morning and 10 mcg at night. Dosage adjusted as needed. If daily dose is divided, each dose adjusted separately.

## **NASAL SPRAY (MINIRIN)**

**Adults.** 10 mcg once daily into one nostril, increased as needed up to 40 mcg once daily. 40-mcg doses may be divided into two or three daily doses.

**Children age 4 and over.** 10 mcg once daily into one nostril, increased as needed up to 30 mcg once daily. 30-mcg dose may be divided into two daily doses, usually with 20 mcg given in morning and 10 mcg given in evening.

- *To prevent or manage bleeding episodes in hemophilia A or mild to moderate type I von Willebrand's disease*

## **I.V. INFUSION**

**Adults and children age 3 months and over weighing more than 10 kg (22 lb).** 0.3 mcg/kg diluted in 50 ml of normal saline solution and infused over 15 to 30 min. If used preoperatively, given 30 min before procedure.

**Children age 3 months and over weighing 10 kg (22 lb) or less.** 0.3 mcg/kg diluted in 10 ml normal saline solution and infused over 15 to 30 min. If used preoperatively, given 30 min before procedure.

## **NASAL SOLUTION (STIMATE)**

**Adults and children weighing 50 kg (110 lb) or more.** 150 mcg in each nostril. If used preoperatively, given 2 hr before procedure.

**Adults and children weighing less than 50 kg (110 lb).** 150 mcg in one nostril. If used preoperatively, given 2 hr before procedure.

Route	Onset	Peak	Duration
P.O.	1 hr*	4-7 hr*	8-12 hr*
I.V.	15-30 min <sup>†</sup>	30-60 min <sup>†</sup>	3 hr <sup>‡</sup>
Nasal	In 1 hr*	1-5 hr*	8-20 hr*

\* For antidiuretic effect.

† For antihemorrhagic effect.

‡ For von Willebrand disease; 4 to 20 hr for mild hemophilia A.

## Mechanism of Action

Exerts an antidiuretic effect similar to that of vasopressin by increasing cellular permeability of renal collecting ducts and distal tubules, thus enhancing water reabsorption, reducing urine flow, and increasing osmolality. As a hemostatic, drug increases blood level of clotting factor VIII (antihemophilic factor) and activity of von Willebrand factor (factor VII<sub>VWF</sub>). It also may increase platelet aggregation and adhesion at injury sites by directly affecting blood vessel walls.

## Contraindications

*All forms:* History or presence of hyponatremia, hypersensitivity to desmopressin or its components, moderate to severe renal impairment (creatinine clearance below 50 ml/min)

*DDVAP, Minirin, and Noctiva only:* Primary nocturnal enuresis

*Intranasal and sublingual forms:* Concurrent therapy with inhaled or systemic glucocorticoids or loop diuretics, during illnesses that can cause fluid and electrolyte imbalance, polydipsia, syndrome of inappropriate antidiuretic hormone (SIADH) secretion

*Nocdurna:* Heart failure

*Noctiva only:* New York Heart Association Class II–IV congestive heart failure

*Nocdurna and Noctiva:* Uncontrolled hypertension

## Interactions

### DRUGS

*carbamazepine, chlorpromazine, lamotrigine, NSAIDs, opioid analgesics, selective serotonin reuptake inhibitors, tricyclic antidepressants:* Possibly increased risk of water intoxication with hyponatremia

*vasopressor drugs:* Possibly potentiated vasopressor effect of desmopressin

## Adverse Reactions

**CNS:** Asthenia, chills, **CVA**, dizziness, headache

**CV:** Hypertension (with high doses), **MI**, **thrombosis**, transient hypotension

**EENT:** Conjunctivitis, epistaxis, lacrimation, nasal congestion (nasal form), ocular edema, pharyngitis, rhinitis, sore throat

**GI:** Abdominal cramps, nausea

**GU:** Vulvar pain (parenteral form)

**RESP:** Cough, upper respiratory infections

**SKIN:** Flushing

**Other:** **Anaphylaxis**, **hyponatremia**, injection-site pain and redness, water intoxication

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Noctiva and Nocdurna brands are not recommended for use during pregnancy.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk but is poorly absorbed orally by the breastfed infant.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use desmopressin cautiously in patients with conditions associated with fluid and electrolyte imbalance, such as cystic fibrosis, heart failure, and renal disorders; these patients are prone to hyponatremia.
- Also use cautiously in patients with habitual or psychogenic polydipsia; they may be more likely to drink excessive water, raising the risk of hyponatremia.
- Be aware that nasal cavity scarring, edema, and other abnormalities may cause erratic absorption and require a different administration route.
- Do not shake bottle of Noctiva before administering. Prime the bottle when using for the first time by pumping 5 actuations into the air away from the face. Re-prime by pumping 2 actuations into the air if the

product has not been used for more than 3 days. Be aware that 2 sprays of 0.83 mcg are not interchangeable with one spray of 1.66-mcg dose.

- Know that the recommended dose for women using the sublingual form of the drug is lower than for men because women are more sensitive to the effects of the sublingual form and have a higher risk of hyponatremia with the 55.3-mcg dose.
- Check blood pressure often during therapy.

**WARNING** Monitor patient closely for evidence of hyponatremia, such as changes in mental status, depressed reflexes, fatigue, headache, lethargy, nausea, restlessness, and vomiting. If left undetected, coma, respiratory arrest, and seizures may occur. Monitor patient's serum sodium level, and notify prescriber of abnormalities.

- Be aware that the nasal spray formulation is not used for the treatment of primary nocturnal enuresis due to a higher risk of hyponatremia and hyponatremic seizures.

## PATIENT TEACHING

- Be aware that to prevent hyponatremia and water intoxication in a child or an elderly patient, family should be urged to restrict patient's fluids as prescribed.
- Tell patient to refrigerate nasal solution.
- Instruct patient who uses nasal spray to prime pump before first use by pressing down four times. Advise her to discard pump after 25 or 50 doses (Stimate) or 50 doses (DDAVP, Minirin), depending on bottle, because delivery of an accurate dose can't be assured.
- Teach patient who uses Noctiva nasal spray not to shake container before administering. Tell patient to prime the container when using for the first time by pumping 5 actuations into the air away from the face. Re-prime by pumping 2 actuations into the air if the product has not been used for more than 3 days. Emphasize to patient that 2 sprays of 0.83 mcg are not interchangeable with one spray of 1.66 mcg.
- Instruct patient taking sublingual tablets to keep tablet under the tongue until it is fully dissolved. Also instruct patient to empty the bladder

immediately before bedtime and to limit fluids to a minimum from 1 hour before until 8 hours after taking drug.

- Teach patient or caregiver how to administer subcutaneous injection, if appropriate.
- Urge patient to report adverse reactions.

## dexamethasone

**Decadon, Dexamethasone Intensol**

**dexamethasone acetate**

**dexamethasone sodium  
phosphate**

## Class and Category

*Pharmacologic class:* Glucocorticoid

*Therapeutic class:* Anti-inflammatory, diagnostic aid, immunosuppressant

## Indications and Dosages

➤ *To treat inflammatory or neoplastic conditions*

### **ELIXIR, ORAL SOLUTION, TABLETS**

**Adults.** Highly individualized dosage based on severity of disorder. *Usual:* 0.75 to 9 mg/day in divided doses.

**Children.** Highly individualized, based on severity of disorder. 0.02 to 0.3 mg/kg/day in three or four divided doses.

➤ *To manage adrenocortical insufficiency*

## **ELIXIR, ORAL SOLUTION, TABLETS, I.V. OR I.M. INJECTION**

**Adults.** 0.5 to 9 mg daily as a single dose or in divided doses.

## **ELIXIR, ORAL SOLUTION, TABLETS**

**Children.** 0.02 to 0.3 mg/kg/day in four divided doses.

➤ *To test for Cushing's syndrome*

## **ELIXIR, ORAL SOLUTION, TABLETS**

**Adults.** 0.5 mg every 6 hr for 48 hr, followed by collection of 24-hr urine specimen to determine 17-hydroxycorticosteroid level. Or, 1 mg at 11 p.m., followed by plasma cortisol test performed at 8 a.m. the next day.

➤ *To distinguish Cushing's syndrome related to pituitary corticotropin excess from Cushing's syndrome from other causes*

## **ELIXIR, ORAL SOLUTION, TABLETS**

**Adults.** 2 mg every 6 hr for 48 hr, followed by collection of 24-hr urine specimen to determine 17-hydroxycorticosteroid level.

➤ *To decrease cerebral edema*

## **ELIXIR, ORAL SOLUTION, TABLETS**

**Adults.** 2 mg every 8 to 12 hr as maintenance after parenteral form has controlled initial symptoms.

## **I.V. INFUSION AND INJECTION**

**Adults.** 10 mg I.V. followed by 4 mg I.M. every 6 hr. Decreased after 2 to 4 days, if needed, gradually tapering off over 5 to 7 days unless inoperable or recurring brain tumor is present. If such a tumor is present, dosage gradually decreased after 2 to 4 days to maintenance dosage of 2 mg I.M. every 8 to 12 hr and switched to P.O. regimen as soon as possible.

- *To treat unresponsive shock*

## **I.V. INFUSION AND INJECTION**

**Adults.** 20 mg as a single dose, followed by 3 mg/kg over 24 hr as a continuous infusion. Alternatively, 40 mg as a single dose, followed by 40 mg every 2 to 6 hr, as needed; or 1 mg/kg to 6 mg/kg as a single dose. All regimens not used more than 3 days.

- *To treat acute exacerbation of multiple sclerosis*

## **ELIXIR, ORAL SOLUTION, TABLETS**

**Adults.** 30 mg/day for 1 wk, followed by 4 to 12 mg every other day for 1 month.

- *To control incapacitating or severe allergic conditions unresponsive to conventional treatment*

## **ELIXIR, I.M INJECTION, ORAL SOLUTION, TABLETS**

**Adults.** *Day 1:* 4 to 8 mg I.M. *Days 2 and 3:* 3 mg/day P.O. divided every 12 hr.

*Day 4:* 1.5 mg/day P.O. divided every 12 hr. *Days 5 and 6:* 0.75 mg/day P.O. as a single dose.

- *To decrease localized inflammation*

## **INTRA-ARTICULAR INJECTION**

**Adults.** 2 to 4 mg for large joint; 0.8 to 1 mg for small joint; 2 to 3 mg for bursae; 0.4 to 1 mg for tendon sheaths.

## **SOFT-TISSUE INJECTION**

**Adults.** 2 to 6 mg; 1 to 2 mg for ganglia.

## **INTRALESIONAL INJECTION**

**Adults.** 0.8 to 1.6 mg/injection site.

## **Mechanism of Action**

Binds to intracellular glucocorticoid receptors and suppresses inflammatory and immune responses by:

- inhibiting monocyte and neutrophil accumulation at inflammation site and suppressing bactericidal and phagocytic action
- stabilizing lysosomal membranes
- suppressing antigen response of helper T cells and macrophages
- inhibiting synthesis of inflammatory response mediators, such as cytokines, interleukins, and prostaglandins.

## **Contraindications**

Administration of live-virus vaccine to patient or family member, hypersensitivity to dexamethasone or its components (including sulfites), idiopathic thrombocytopenic purpura (I.M. administration), systemic fungal infections

## **Interactions**

## **DRUGS**

*aminoglutethimide*: Possibly diminished adrenal suppression by dexamethasone

*amphotericin B (parenteral), potassium depleting drugs*: Risk of hypokalemia

*anticholinesterases*: Decreased anticholinesterase effectiveness in myasthenia gravis producing severe weakness

*aspirin, NSAIDs*: Increased risk of adverse GI effects

*cholestyramine*: Increased dexamethasone clearance

*cyclosporine*: Increased activity of both drugs, possibly resulting in seizures

*CYP3A4 inducers such as barbiturates, carbamazepine, phenytoin, rifampin*: Possibly enhanced metabolism of dexamethasone requiring dosage increase

*CYP3A4 inhibitors such as clarithromycin, cobicistat-containing drugs, itraconazole, ritonavir*: Possibly increased plasma concentrations of dexamethasone with increased adverse reactions

*CYP3A4 substrates such as erythromycin, indinavir*: Possibly decreased plasma concentration of these drugs

*digoxin*: Increased risk of digitalis toxicity related to hypokalemia

*ephedrine*: Decreased half-life and increased clearance of dexamethasone

*isoniazid*: Decreased blood isoniazid level

*macrolide antibiotics*: Decreased dexamethasone clearance and increased dexamethasone effects

*oral anticoagulants such as warfarin*: Inhibition of response to oral anticoagulant

*oral contraceptives including estrogens*: Increased effect of oral contraceptives

*phenytoin*: Increased risk of seizures

*thalidomide*: Increased risk of toxic epidermal necrolysis

*toxoids, vaccines*: Decreased antibody response

## ACTIVITIES

*alcohol use:* Increased risk of GI bleeding

## Adverse Reactions

**CNS:** Depression, emotional lability, euphoria, fever, headache, **increased intracranial pressure (ICP) with papilledema**, insomnia, light-headedness, malaise, neuritis, neuropathy, paresthesia, psychosis, **seizures**, syncope, tiredness, vertigo, weakness

**CV:** **Arrhythmias**, **bradycardia**, edema, **fat embolism**, **heart failure**, hypercholesterolemia, hyperlipidemia, hypertension, **myocardial rupture**, tachycardia, **thromboembolism**, thrombophlebitis, vasculitis

**EENT:** Blurred vision, cataracts, exophthalmos, glaucoma, ocular infections, *All forms:* Epistaxis, loss of smell and taste, nasal burning and dryness, oral candidiasis, perforated nasal septum, pharyngitis, rebound nasal congestion, rhinorrhea

**ENDO:** Cushingoid symptoms, decreased iodine uptake, growth suppression in children, hyperglycemia, menstrual irregularities, **secondary adrenocortical and pituitary unresponsiveness**

**GI:** Abdominal distention, bloody stools, elevated liver enzymes, heartburn, hepatomegaly, increased appetite, indigestion, **intestinal perforation**, **melena**, nausea, **pancreatitis**, peptic ulcer **with possible perforation**, ulcerative esophagitis, vomiting

**GU:** Glycosuria, increased or decreased number and motility of spermatozoa, perineal irritation, urinary frequency

**HEME:** Leukocytosis, **leukopenia**

**MS:** Aseptic necrosis of femoral and humeral heads; muscle atrophy, spasms, or weakness; myalgia; osteoporosis; pathologic fracture of long bones; tendon rupture (intra-articular injection); vertebral compression fracture

**RESP:** **Bronchospasm**

**SKIN:** Acne, allergic dermatitis, diaphoresis, ecchymosis, erythema, hirsutism, necrotizing vasculitis, petechiae, subcutaneous fat atrophy, striae, thin and fragile skin, urticaria

**Other:** Aggravated or masked signs of infection, **anaphylaxis**, **angioedema**, **hypernatremia**, **hypocalcemia**, **hypokalemia**, **hypokalemic alkalosis**, impaired wound healing, **metabolic acidosis**, suppressed skin test reaction, **tumor lysis syndrome**, weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm. However, infants born of mothers who have received substantial doses of drug during pregnancy may develop hypoadrenalism.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

# Nursing Considerations

- Use dexamethasone cautiously in patients with congestive heart failure, hypertension, or renal insufficiency because drug can cause sodium retention, which may lead to edema and hypokalemia.
- Also use cautiously in patients who have had intestinal surgery and in those with diverticulitis, peptic ulcer, or ulcerative colitis because of the risk of perforation.
- Give once-daily dose of dexamethasone in the morning to coincide with the body's natural cortisol secretion.
- Give oral drug with food to decrease GI distress.
- Be aware that dosage forms with a concentration of 24 mg/ml are for I.V. use only.
- Shake I.M. solution before injecting deep into large muscle mass.

**WARNING** Avoid subcutaneous injection; it may cause atrophy and sterile abscess.

- Inject undiluted I.V. dose directly into I.V. tubing of infusing compatible solution over 30 seconds or less, as prescribed.

**WARNING** Don't give acetate form by I.V. injection.

- Expect to taper drug rather than stopping it abruptly; prolonged use can cause adrenal suppression.
- Monitor fluid intake and output and daily weight, and watch for crackles, dyspnea, peripheral edema, and steady weight gain.
- Evaluate growth if patient is a child.
- Test stool for occult blood.
- Monitor results of hematology studies and blood glucose, cholesterol, lipids levels, and serum electrolyte. Dexamethasone may cause hyperglycemia, hyponatremia, hypocalcemia, hypokalemia, or leukopenia. It also may increase serum cholesterol and lipid levels, and it may decrease iodine uptake by the thyroid.
- Assess patient for evidence of Cushing's syndrome, osteoporosis, and other systemic effects during long-term use.

- Monitor neonate for signs of hypoadrenocorticism if mother received dexamethasone during pregnancy. Be aware that some preparations contain benzyl alcohol, which may cause a fatal toxic syndrome in neonates and immature infants.
- Watch for hypersensitivity reactions after giving acetate or sodium phosphate form; both may contain bisulfites or parabens, to which some people are allergic.
- Be aware that the use of corticosteroids such dexamethasone, especially for longer than 6 weeks, increases the risk of development of eye disorders, including cataracts and glaucoma, which can possibly damage the optic nerves, and ocular infections due to bacteria, fungi, or viruses. Know that patient should be referred to an ophthalmologist if patient develops ocular symptoms while taking dexamethasone.

## **PATIENT TEACHING**

- Instruct patient not to store drug in damp or hot places and to protect liquid form from freezing.
- Instruct patient to take once-daily oral dose in the morning with food to help prevent GI distress.
- Caution against consuming alcohol during dexamethasone therapy because it increases the risk of GI bleeding.
- Advise patient to follow a low-sodium, high-potassium, high-protein diet, if prescribed, to help minimize weight gain, which is common with dexamethasone therapy. Instruct her to inform prescriber if she's on a special diet.
- Instruct patient not to stop drug abruptly.
- Advise patient to notify prescriber if condition recurs or worsens after dosage is reduced or therapy stops.
- Urge patient to have regular eye examinations during long-term use and to report any eye abnormalities to prescriber.
- Advise patient on long-term therapy to carry medical identification and to notify all healthcare providers that she takes dexamethasone.
- Instruct patient (especially a child) to avoid close contact with anyone who has chickenpox or measles and to notify prescriber immediately if exposure occurs.

- Advise patient and family members to avoid live-virus vaccinations during therapy unless prescriber approves.
- Inform diabetic patient that drug may affect her blood glucose level.
- Instruct patient having drug injected into a joint to avoid putting excessive pressure on it and to notify prescriber if it becomes red or swollen.
- Tell patient to notify prescriber about anorexia, depression, light-headedness, malaise, muscle pain, nausea, vomiting, and early hyperadrenocorticism (abdominal distention, amenorrhea, easy bruising, extreme weakness, facial hair, increased appetite, moon face, weight gain). Tell patient and family about possible changes in appearance.
- Urge patient to notify prescriber about illness, surgery, or changes in stress level.

## dexmethylphenidate hydrochloride

**Focalin, Focalin XR**

### **Class, Category, and Schedule**

*Pharmacologic class: Methylphenidate derivative*

*Therapeutic class: CNS stimulant*

*Controlled substance schedule: II*

### **Indications and Dosages**

- *To treat attention deficit hyperactivity disorder (ADHD)*

#### **TABLETS (FOCALIN)**

**Adults and children age 6 and over who are new to methylphenidate or who are on stimulants other than methylphenidate.** 2.5 mg twice daily at least 4 hr apart, increased weekly by 2.5 to 5 mg. *Maximum:* 10 mg twice daily.

**Adults and children age 6 and over who take methylphenidate.** Half of the current daily methylphenidate dosage, increased weekly, as needed. *Maximum:* 10 mg twice daily at least 4 hr apart.

## **E.R. CAPSULES (FOCALIN XR)**

**Adults who are new to methylphenidate. or who are on stimulants other than methylphenidate.** 10 mg daily, increased weekly by 10 mg daily, as needed. *Maximum:* 40 mg daily.

**Children age 6 and over who are new to methylphenidate or who are on stimulants other than methylphenidate.** 5 mg daily, increased weekly as needed by 5-mg increments. *Maximum:* 30 mg daily.

**Adults and children age 6 and over who take methylphenidate.** Half of the current total daily methylphenidate dosage increased weekly, as needed. *Maximum:* 40 mg daily (adults) and 30 mg daily (children).

***DOSAGE ADJUSTMENT*** Dosage decreased for paradoxical aggravation of symptoms or adverse reactions.

## **Mechanism of Action**

May block reuptake of dopamine and norepinephrine into presynaptic neurons in cerebral cortex, which increases availability of dopamine and norepinephrine in extraneuronal space.

# Contraindications

Hypersensitivity to dexamethylphenidate, methylphenidate, or their components; use within 14 days of MAO inhibitor

# Interactions

## DRUGS

*antihypertensives*: Decreased therapeutic effect of these drugs

*halogenated anesthetics*: Increased risk of sudden blood pressure and heart rate acceleration during surgery

*MAO inhibitors*: Increased adverse effects, risk of hypertensive crisis

*serotonergic drugs*: Increased risk of serotonin syndrome

# Adverse Reactions

**CNS**: Aggression, anxiety, **cerebral arteritis or occlusion**, **CVA**, depression, dizziness, drowsiness, dyskinesia, fever, headache, insomnia, motor or vocal tics, nervousness, psychosis, **seizures**, Tourette syndrome, toxic psychosis, tremor

**CV**: Angina, **arrhythmias**, decreased or increased pulse rate, hypertension, **hypotension**, **MI**, palpitations, peripheral vasculopathy including Raynaud's phenomenon, tachycardia, vasculitis

**EENT**: Accommodation abnormality, blurred vision, dry mouth, nasopharyngitis

**ENDO**: Suppression of growth (children)

**GI**: Abdominal pain, anorexia, dyspepsia, elevated liver enzymes, **hepatic dysfunction (may be severe)**, nausea,

vomiting

**GU:** Libido changes, priapism

**HEME:** Anemia, **leukopenia**, **thrombocytopenia**, **thrombocytopenic purpura**

**MS:** Arthralgia, muscle cramps, **rhabdomyolysis**

**RESP:** Cough

**SKIN:** Alopecia, **erythema multiforme**, excessive diaphoresis, **exfoliative dermatitis**, necrotizing vasculitis, pruritis, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, physical and psychological dependence, weight loss (prolonged therapy in adults)

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-961-2388 or visit <https://womensmentalhealth.org/adhd-medications/>.
- It is not known if drug causes fetal harm but drug may cause vasoconstriction which may decrease placental perfusion.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, infant should be monitored for adverse reactions, such as agitation, anorexia, insomnia, and reduced weight gain.

# Nursing Considerations

- Know that dexamethylphenidate should not be given to patients with cardiomyopathy, coronary artery disease, known serious structural cardiac abnormalities, serious heart rhythm abnormalities, and other serious heart problems because of risk of CVA, MI, or sudden death. Notify prescriber if patient develops arrhythmias, unexplained syncope, or exertional chest pain.

**WARNING** Be aware that dexamethylphenidate may induce CNS stimulation, mania, and psychosis and may worsen behavior disturbances and thought disorders. Use drug cautiously in children with mania or psychosis. Be aware that withdrawal symptoms may occur with long-term use.

- Monitor blood pressure and pulse rate to detect hypertension and excessive stimulation. Notify prescriber if signs appear.

**WARNING** Monitor patient for signs of physical or psychological dependence. Use drug cautiously in patients with a history of drug abuse, including alcoholism.

- Monitor CBC and differential and platelet counts, as ordered, during prolonged therapy.
- Expect to stop drug if seizures occur. Drug may lower seizure threshold, especially in patients with a history of seizures or EEG abnormalities.
- Assess patient for signs and symptoms of peripheral vasculopathy, including Raynaud's phenomenon. Although mild and intermittent, know that digital ulceration and/or soft tissue breakdown has occurred. Notify prescriber if present, as drug dosage may need to be reduced or drug discontinued.

**WARNING** Question male patients, including male children, about painful and prolonged erections, especially after a dosage increase or during a period of drug withdrawal. Know that presence of priapism has

sometimes required emergency surgical intervention, so report any findings to prescriber immediately.

- Monitor children on long-term dexamethylphenidate therapy for signs of growth suppression, which has been noted during long-term use of stimulants.

## PATIENT TEACHING

- Tell patient that extended-release capsules should either be taken whole, without being chewed, crushed, or divided, or capsule contents should be sprinkled on a small amount of applesauce.

**WARNING** Stress importance of notifying prescriber if an irregular pulse, fainting, or chest pain on exertion develops.

- Urge patient to notify prescriber if she has excessive nervousness, fever, insomnia, nausea, palpitations, or rash while taking dexamethylphenidate.
- Caution patient with seizure disorder that drug may cause seizures.
- Advise patient to protect drug from light and moisture.
- Teach patient (or parent) to watch for improvement in signs and symptoms of ADHD, such as decreased impulsiveness and increased attention. Stress the need for continued follow-up care, and suggest participation in an ADHD program.

**WARNING** Inform male patients and parents or caregivers of male children that dexamethylphenidate may cause abnormally sustained or frequent and painful erections, especially when a dosage increase occurs or during a period of drug withdrawal. Advise immediate emergency care if this should occur.

- Instruct patient to inspect his fingers and toes daily for changes such as skin breakdown or ulcer formation. Although usually intermittent and mild, patient should contact prescriber if abnormalities occur, as drug may have to be discontinued or dosage reduced.

# diazepam

**Diastat, Diazepam Intensol, Dizac, Valium**

## Class, Category, and Schedule

*Pharmacologic class:* Benzodiazepine

*Therapeutic class:* Anticonvulsant, anxiolytic, sedative-hypnotic, skeletal muscle relaxant

*Controlled substance schedule:* IV

## Indications and Dosages

➤ *To relieve anxiety*

### ORAL SOLUTION, TABLETS

**Adults.** 2 to 10 mg twice daily to four times daily.

***DOSAGE ADJUSTMENT*** Dosage reduced to 2 to 2.5 mg daily or twice daily and increased gradually as needed and tolerated for debilitated or elderly patients.

### I.V. OR I.M. INJECTION

**Adults.** *For moderate anxiety:* 2 to 5 mg every 3 to 4 hr, as needed. *For severe anxiety:* 5 to 10 mg, repeated in 3 to 4 hr, if needed. I.V. injection given slowly, not exceeding 5 mg/min.

➤ *To treat symptoms of acute alcohol withdrawal*

### ORAL SOLUTION, TABLETS

**Adults.** 10 mg three times daily or four times daily during first 24 hr. Then 5 mg three times daily or four times daily, if needed.

## **I.V. OR I.M. INJECTION**

**Adults.** 10 mg and then 5 to 10 mg in 3 to 4 hr, if needed. I.V. injection given slowly, not exceeding 5 mg/min.

➤ *As adjunct to treat muscle spasms*

## **ORAL SOLUTION, TABLETS**

**Adults.** 2 to 10 mg three times daily or four times daily.

**DOSAGE ADJUSTMENT** Dosage reduced to 2 to 2.5 mg once or twice daily and increased gradually as needed and tolerated for debilitated or elderly patients.

**Children age 6 months and over.** *Initial:* 1 to 2.5 mg three times daily or four times daily. Increased gradually as needed and tolerated.

## **I.V. OR I.M. INJECTION**

**Adults.** *Initial:* 5 to 10 mg, then repeated every 3 to 4 hr, as needed. I.V. injection given slowly, not exceeding 5 mg/min.

➤ *To treat seizures*

## **ORAL SOLUTION, TABLETS**

**Adults.** 2 to 10 mg twice daily to four times daily.

**DOSAGE ADJUSTMENT** Dosage reduced to 2 to 2.5 mg once or twice daily and increased gradually as needed and tolerated for debilitated or elderly patients.

**Children age 6 months and over.** *Initial:* 1 to 2.5 mg three times daily or four times daily. Increased gradually as needed and tolerated.

- *To treat status epilepticus and severe recurrent seizures*

## **I.V. INJECTION**

**Adults.** 5 to 10 mg given slowly, not exceeding 5 mg/min, repeated every 10 to 15 min, as needed, up to a cumulative dose of 30 mg. Regimen repeated, if needed, in 2 to 4 hr. (Use I.M. route if I.V. access is impossible.)

**Children age 5 and over.** 1 mg given slowly over 3 min, not exceeding 0.25 mg/kg, repeated every 2 to 5 min, as needed, up to a cumulative dose of 10 mg. Regimen repeated, if needed, in 2 to 4 hr.

**Children ages 1 month to 5 years.** 0.2 to 0.5 mg given slowly over 3 min, not exceeding 0.25 mg/kg, repeated every 2 to 5 min, as needed, up to a cumulative dose of 5 mg. Regimen repeated, if needed, in 2 to 4 hr.

- *As adjunct to manage bouts of increased seizure activity*

## **RECTAL GEL (DIASTAT)**

**Adults and adolescents.** 0.2 mg/kg rounded up to next available unit dose (or rounded down for debilitated or elderly patient). Repeated in 4 to 12 hr, if needed.

**Children ages 6 to 12.** 0.3 mg/kg rounded up to next available unit dose. Repeated in 4 to 12 hr, if needed.

**Children ages 2 to 6.** 0.5 mg/kg rounded up to next available unit dose. Repeated in 4 to 12 hr, if needed.

- *To provide preoperative sedation*

## **I.V. OR I.M. INJECTION**

**Adults.** 10 mg 30 min before surgery with I.M. route preferred. I.V. injection given slowly, not exceeding 5 mg/min.

- *To reduce anxiety before cardioversion*

## **I.V. INJECTION**

**Adults.** 5 to 15 mg given slowly, not exceeding 5 mg/min, 5 to 10 min before procedure.

- *To reduce anxiety before endoscopic procedures*

## **I.V. INJECTION**

**Adults.** Up to 20 mg given slowly, not exceeding 5 mg/min, titrated to desired sedation and given immediately before procedure.

## **I.M. INJECTION**

**Adults.** 5 to 10 mg 30 min before procedure.

- *To treat tetanus*

## **I.V. OR I.M. INJECTION**

**Adults and children age 5 and over.** *Initial:* 5 to 10 mg repeated every 3 to 4 hr, if needed. I.V. injection given slowly, not exceeding 5 mg/min for adults, and given slowly over 3 min and not exceeding 0.25 mg/kg for children. Sometimes larger doses are needed for adults.

***DOSAGE ADJUSTMENT*** Initial dose reduced to 2 to 5 mg and increased gradually as needed and tolerated for debilitated patients.

**Children ages 1 month to 5 years.** 1 to 2 mg repeated every 3 to 4 hr, as needed. I.V. injection given slowly over 3 min, not exceeding 0.25 mg/kg.

## **Mechanism of Action**

May potentiate effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptors in cortical and limbic areas of CNS. GABA inhibits excitatory stimulation, which helps control emotional behavior. Limbic system contains a dense area of benzodiazepine receptors, which may explain drug's antianxiety effects. Diazepam suppresses spread of seizure activity caused by seizure-producing foci in cortex, limbic, and thalamus structures.

## **Incompatibilities**

Don't mix diazepam injection with aqueous solutions. Don't mix diazepam emulsion for I.M. injection with glycopyrrolate or morphine or administer it through an infusion set that contains polyvinyl chloride.

## **Contraindications**

*For all forms:* Acute angle-closure glaucoma, hypersensitivity to diazepam or its components, untreated open-angle glaucoma

*For oral forms:* Children under 6 months of age, myasthenia gravis, severe hepatic impairment, severe respiratory insufficiency, sleep apnea

## **Interactions**

### **DRUGS**

*antacids:* Altered rate of diazepam absorption  
*cimetidine, fluoxetine, fluvoxamine, ketoconazole, omeprazole* Decreased diazepam metabolism, increased blood level and risk of adverse effects including prolonged sedation

*CNS depressants including anesthetics, anticonvulsants, antipsychotics, anxiolytics, barbiturates, hypnotics, MAO inhibitors, narcotics, phenothiazines, sedatives including sedative antihistamines, and other antidepressants:*  
Increased CNS depression and risk of falls and fractures  
*opioids:* Increased risk of severe respiratory depression  
*phenytoin:* Decreased metabolic elimination of phenytoin, increased risk of adverse reactions

## **ACTIVITIES**

*alcohol use:* Increased CNS depression, including severe respiratory depression, significant sedation and somnolence, and increased risk of falls and fractures

## **Adverse Reactions**

**CNS:** Anterograde amnesia, anxiety, ataxia, confusion, depression, dizziness, drowsiness, fatigue, headache, insomnia, lethargy, light-headedness, paradoxical reactions, psychiatric effects, sedation, sleepiness, slurred speech, **suicidal ideation**, tremor, vertigo

**CV:** **Hypotension**, palpitations, tachycardia

**EENT:** Blurred vision, diplopia, dry mouth, increased salivation

**GI:** Anorexia, constipation, diarrhea, elevated liver enzymes, jaundice, nausea, vomiting

**GU:** Libido changes, urinary incontinence, urine retention

**HEME:** **Neutropenia**

**MS:** Dysarthria, muscle weakness

**RESP:** **Respiratory depression**

**SKIN:** Dermatitis

**Other:** Physical and psychological dependence

## **Childbearing Considerations**

### **PREGNANCY**

- Drug may cause fetal harm. An increased risk of congenital malformations and other developmental abnormalities have occurred with benzodiazepines such as diazepam.
- Drug may also cause nonteratogenic issues after birth such as feeding difficulties, neonatal flaccidity, hypothermia, and respiratory problems.
- Know that if drug is given on a regular basis late in pregnancy, the neonate may experience withdrawal symptoms after birth.
- Drug should not be used during pregnancy, especially in the first and third trimester, unless there is no alternative and the benefit to the mother outweighs the risk to the fetus.

### **LABOR & DELIVERY**

- Be aware that high single doses of the drug during labor and delivery may cause fetal heart rate irregularities and after birth hypotonia, hypothermia, poor sucking, and moderate respiratory depression.

### **LACTATION**

- Drug is present in breast milk.
- Patient should not breastfeed while taking drug.

## **Nursing Considerations**

- Use diazepam with extreme caution in patients with a history of alcohol or drug abuse because it can cause physical and psychological dependence, and in patients with hepatic disorders such as hepatic fibrosis and hepatitis because of potentially significant increase in drug's half-life.
- Use diazepam cautiously in patients with hepatic or renal impairment.

- Expect to give a lower diazepam dose to patient with chronic respiratory insufficiency because of the risk of respiratory depression.
- Mix concentrated oral solution (Intensol) with liquid or semisolid food. Use supplied calibrated dropper to measure doses.
- Protect diazepam injection from light. Don't use solution that's more than slightly yellow or that contains precipitate.
- Give I.M. injection into deltoid muscle for rapid, complete absorption. Using other sites may cause slow, erratic absorption.
- Know that for an infant or a child, administer I.V. injection slowly over 3 minutes in a dose not to exceed 0.25 mg/kg. For an adult, administer I.V. injection no more than 5 mg/minute and if possible into a large vein or, if not possible, inject through infusion tubing as close to the insertion site as possible.
- Monitor patient for adverse reactions, especially if she has hypoalbuminemia, which increases the risk of sedation.

**WARNING** Watch for signs of physical and psychological dependence (strong desire or need to continue taking diazepam, need to increase dose to maintain drug effects, and posttherapy withdrawal symptoms, such as abdominal cramps, insomnia, irritability, nervousness, and tremor).

- Monitor patient closely for increase in frequency or severity of grand mal seizures when diazepam is used with standard anticonvulsant therapy. Dosage of other anticonvulsants may have to be increased.
- Avoid abrupt withdrawal of diazepam, as ordered, when used as part of the patient's seizure control regimen because a transient increase in frequency or severity of seizures may occur.
- Monitor severely depressed patient or one with depression-related anxiety for suicidal tendencies, particularly when therapy starts and dosage changes; depression may worsen temporarily during these times.
- Watch for paradoxical and psychiatric reactions to diazepam, especially in children and the elderly. If reactions occur, notify prescriber and expect drug to be discontinued.
- Monitor patient for decreased drug effectiveness, especially with prolonged use.

**WARNING** Be aware that benzodiazepine therapy like diazepam should only be used concomitantly with opioids in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of the opioid to be limited. Monitor patient closely for signs and symptoms of decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

- Check patient's blood counts and liver function periodically, as ordered, because prolonged diazepam therapy rarely causes jaundice and neutropenia.

## **PATIENT TEACHING**

- Instruct patient not to take more drug, more often, or for a longer time than prescribed. Warn her that physical and psychological dependence can occur, and teach her to recognize the signs.
- Advise patient not to take drug to relieve everyday stress.
- Instruct patient to avoid hazardous activities until drug's CNS effects are known. Warn her that risk of falls and fractures increases when diazepam is taken with other sedatives or alcohol and to avoid this combination.
- Advise patient to avoid CNS depressants during therapy.

**WARNING** Warn patient not to consume alcohol or take an opioid during diazepam therapy without prescriber knowledge, as severe respiratory depression can occur and may lead to death.

**WARNING** Inform patient about potentially fatal additive effects of combining diazepam with an opioid. Instruct patient to inform all prescribers of diazepam use, especially if pain medication may be prescribed.

- Instruct patient not to stop taking drug abruptly without prescriber's supervision. If patient has a history of seizures, warn that abrupt withdrawal may trigger them.
- Instruct patient to mix Diazepam Intensol with water, soda, or a similar beverage; applesauce; or pudding just before taking it. Caution her not to save the mixture for later. Tell her to use calibrated dropper that's provided to measure each dose.
- Teach patient how to self-administer a rectal form, if prescribed.
- Instruct female patient of childbearing age to notify prescriber immediately if she is or could be pregnant because diazepam therapy will need to be discontinued.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.

## diazoxide

### Hyperstat, Proglycem

## Class and Category

*Pharmacologic class:* Benzothiadiazine derivative

*Therapeutic class:* Antihypertensive, antihypoglycemic

## Indications and Dosages

➤ *To manage hypoglycemia caused by hyperinsulinism*

### **CAPSULES, ORAL SUSPENSION (PROGLYCEM)**

**Adults and children.** *Initial:* 1 mg/kg every 8 hr.

*Maintenance:* 3 to 8 mg/kg daily in 2 or 3 equal doses given every 8 or 12 hr. *Maximum:* 15 mg/kg daily.

**Infants and neonates.** *Initial:* 3.3 mg/kg every 8 hr.  
*Maintenance:* 8 to 15 mg/kg daily in 2 or 3 equal doses given every 8 or 12 hr.

➤ *To treat severe hypertension in hospitalized patients*

## **I.V. INJECTION (HYPERSTAT)**

**Adults.** *Initial:* 1 to 3 mg/kg by rapid bolus, repeated every 5 to 15 min until diastolic pressure falls below 100 mm Hg. Repeated in 4 to 24 hr, if needed, until oral antihypertensive therapy begins. *Maximum:* 150 mg/dose, 1.2 g daily.

Route	Onset	Peak	Duration
P.O.	In 1 hr	Unknown	8 hr
I.V.	1 min	2-5 min	2-12 hr

## **Mechanism of Action**

Directly affects smooth muscle cells of peripheral arteries and arterioles, causing them to dilate. This action decreases peripheral resistance, which helps reduce blood pressure. Diazoxide also inhibits insulin release from the pancreas, stimulates catecholamine release, and increases hepatic glucose release.

## **Contraindications**

Acute aortic dissection; functional hypoglycemia (Polyglycem), hypersensitivity to diazoxide, thiazides, other sulfonamide derivatives, or their components; treatment of compensatory hypertension, as occurs with aortic coarctation or arteriovenous shunt (Hyperstat)

# Interactions

## DRUGS

*antihypertensives, beta blockers, nitrates*: Additive hypotensive effects

*beta blockers*: Increased hypotensive effects of diazoxide

*diphenylhydantoin*: Increased risk of loss of seizure control

*diuretics, especially thiazides*: Potentiated hyperglycemic, hyperuricemic, and antihypertensive effects of diazoxide

*oral anticoagulants*: Increased anticoagulation

*peripheral vasodilators*: Additive, possibly severe, hypotensive effects

## Adverse Reactions

**CNS**: Anxiety, apprehension, **cerebral ischemia**, dizziness, euphoria, headache, insomnia, light-headedness, malaise, somnolence, weakness

**CV**: **Bradycardia**, chest pain, edema, **hypotension**, palpitations, tachycardia, transient hypertension

**EENT**: Blurred vision, dry mouth, increased salivation, taste perversion, tinnitus, transient hearing loss

**ENDO**: Transient hyperglycemia

**GI**: Abdominal pain, anorexia, constipation, diarrhea, ileus, nausea, vomiting

**MS**: Gout

**RESP**: **Pulmonary hypertension**

**SKIN**: Diaphoresis, flushing, pruritus, rash, sensation of warmth

**Other**: Extravasation with injection-site cellulitis and pain; **hypernatremia**

# Childbearing Considerations

## PREGNANCY

- Drug may cause fetal harm if given to mother just prior to delivery possibly causing altered carbohydrate metabolism, fetal or neonatal hyperbilirubinemia, thrombocytopenia, or other adverse effects.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LABOR & DELIVERY

- Be aware drug is not indicated for use during labor and delivery because it may cause cessation of uterine contractions.

## LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

# Nursing Considerations

- Use diazoxide cautiously in patients with uncompensated heart failure (can cause fluid retention and heart failure) and patients with impaired cardiac or cerebral circulation in whom abrupt blood pressure drop, mild tachycardia, and decreased blood perfusion may be harmful.
- Give I.V. drug undiluted over 10 to 30 seconds. Don't give it I.M. or subcutaneously.
- Keep patient supine during I.V. injection and for 1 hour afterward.
- Monitor blood pressure throughout treatment to check for changes. Know that risk for hypotension is increased in patients taking thiazide diuretics. Before monitoring ends, measure patient's standing blood pressure if she's ambulatory.
- Assess I.V. site often for extravasation; drug is alkaline and can irritate tissue.

- Expect to adjust dosage if patient switches from oral suspension to capsules; suspension causes a higher blood diazoxide level.
- Know that if diabetic patient receives I.V. diazoxide to treat hypertension, patient should be watched for evidence of hyperglycemia, because parenteral form commonly causes transient hyperglycemia.
- Monitor blood glucose level of all patients who receive oral diazoxide to see if drug has raised blood glucose level to normal.

**WARNING** Monitor infants and neonates closely for pulmonary hypertension exhibited by respiratory distress. If present, notify prescriber immediately and expect drug to be discontinued because condition can be reversed when drug therapy is stopped.

## PATIENT TEACHING

- Tell patient who receives I.V. diazoxide that she'll be on bed rest until taking oral drug.
- Advise patient to protect oral suspension from light.
- Tell patient to take oral drug on a regular schedule and not to skip or double doses.
- Urge patient to monitor blood glucose level if she takes oral drug for hypoglycemia.
- Caution patient not to take antidiabetic drugs unless prescribed.
- Advise patient to notify prescriber if she has signs of hyperglycemia, such as fatigue, or increased hunger, thirst, or urinary frequency.

## diclofenac

**Zorvolex diclofenac epolamine  
Flector Topical System**

## diclofenac potassium

**Cambia, Voltaren Rapide (CAN), Zipsor**

## diclofenac sodium

**Apo-Diclo (CAN), Dyloject, Voltaren, Voltaren SR (CAN)**

### Class and Category

*Pharmacologic class:* NSAID

*Therapeutic class:* Analgesic, anti-inflammatory

### Indications and Dosages

- *To manage signs and symptoms of rheumatoid arthritis*

#### **TABLETS**

**Adults.** 50 mg three or four times daily or 75 mg twice daily.

#### **DELAYED-RELEASE TABLETS**

**Adults.** *Initial:* 50 mg three times daily or four times daily or 75 mg twice daily. *Maximum:* 200 mg daily.

#### **E.R. TABLETS**

**Adults.** *Initial:* 100 mg daily, increased to 200 mg daily and divided into two equal doses, morning or evening as needed.

➤ *To manage signs and symptoms of osteoarthritis*

## **CAPSULES (ZORVOLEX)**

**Adults.** 35 mg three times daily.

## **TABLETS**

**Adults.** 50 mg two or three times daily or 75 mg twice daily.

## **DELAYED-RELEASE TABLETS**

**Adults.** 50 mg twice daily or three times daily or 75 mg twice daily.

## **E.R. TABLETS**

**Adults.** 100 mg daily.

➤ *To relieve pain in patients with ankylosing spondylitis*

## **DELAYED-RELEASE TABLETS, TABLETS**

**Adults.** 25 mg four times daily, with an extra 25 mg dose at bedtime, if needed.

➤ *To relieve pain and dysmenorrhea*

## **TABLETS**

**Adults.** 50 mg three times daily, as needed; if needed, 100 mg for first dose only.

➤ *To manage mild to moderate pain; to manage moderate to severe pain alone or in combination with opioid analgesics*

## I.V. INJECTION (DYLOJECT)

**Adults.** 37.5 mg given over 15 seconds every 6 hours, as needed. *Maximum:* 150 mg daily.

- *To relieve mild to moderate acute pain*

## CAPSULES (ZIPSOR)

**Adults.** 25 mg four times daily.

## CAPSULES (ZORVOLEX)

**Adults.** 18 mg or 35 mg three times daily.

- *To treat acute migraine attacks*

## ORAL SOLUTION (CAMBIA)

**Adults.** 50 mg (1 packet) per attack.

- *To relieve pain due to minor contusions, sprains, or strains*

## TOPICAL SYSTEM 1.3%

**Adults and children 6 years and over.** 1 patch to the most painful area twice a day.

***DOSAGE ADJUSTMENT*** For patient prescribed Zorvolex with hepatic impairment, dosage no higher than 18 mg three times daily. For patient prescribed other drug forms with hepatic impairment, dosage may have to be reduced.

Route	Onset	Peak	Duration
P.O.*	30 min	Unknown	8 hr

\* For tablets; unknown for delayed-release and E.R. tablets.

## Mechanism of Action

Blocks the activity of cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate inflammatory response and cause local pain, swelling, and vasodilation. By blocking cyclooxygenase and inhibiting prostaglandins, diclofenac reduces inflammatory symptoms. This mechanism also relieves pain because prostaglandins promote pain transmission from periphery to spinal cord.

## Contraindications

Active GI bleeding or ulcers; history of asthma attacks, rhinitis, or urticaria from aspirin or other NSAIDs; hypersensitivity to diclofenac, NSAIDs, or their components; moderate to severe renal insufficiency in perioperative period with patients at risk for volume depletion (I.V. form); pain management following coronary artery bypass graft (CABG) surgery; use on damaged or nonintact skin (topical system)

## Interactions

### DRUGS

*angiotensin-converting enzyme (ACE) inhibitors, angiotensin receptor blockers (ARBs):* Decreased antihypertensive effects of these drugs; decreased renal function in elderly patients or those with existing renal impairment or volume depletion  
*anticoagulants, antiplatelets, selective serotonin reuptake inhibitors (SSRIs), serotonin norepinephrine reuptake inhibitors (SNRIs), thrombolytics:* Prolonged PT, increased risk of bleeding  
*aspirin, other NSAIDs, salicylates:* Increased GI irritability and bleeding, decreased diclofenac effectiveness with aspirin use

*beta blockers*: Impaired antihypertensive effect  
*cyclosporine, nephrotoxic drugs*: Increased risk of nephrotoxicity  
*CYP2C9 inducers such as rifampin*: Decreased effectiveness of diclofenac  
*CYP2C9 inhibitors such as voriconazole*: Increased risk of diclofenac adverse reactions and toxicity  
*digoxin*: Increased blood digoxin level  
*lithium*: Increased risk of lithium toxicity  
*loop or thiazide diuretics*: Decreased diuretic effects  
*methotrexate, pemetrexed*: Increased risk of methotrexate or pemetrexed toxicity

## **FOODS**

*any food*: Delayed absorption of delayed-release tablets

## **ACTIVITIES**

*alcohol use*: Increased risk of GI irritability and bleeding

## **Adverse Reactions**

**CNS**: Aseptic meningitis, cerebral hemorrhage, CVA, dizziness, drowsiness, headache

**CV**: Bradycardia and other arrhythmias, edema, heart failure, hypotension, MI, thrombotic events, vasculitis

**EENT**: Glaucoma, hearing loss, tinnitus

**ENDO**: Hypoglycemia

**GI**: Abdominal pain, constipation, diarrhea, dysphagia, elevated liver enzymes, esophageal ulceration, flatulence, GI bleeding or ulceration, hepatic failure, hepatitis, indigestion, jaundice, nausea, perforation of intestine or stomach

**GU:** Acute renal failure, interstitial nephritis

**HEME:** Agranulocytosis, anemia including aplastic anemia, bleeding events, eosinophilia, leukocytosis, leukopenia, pancytopenia, porphyria, thrombocytopenia

**SKIN:** Erythema multiforme, exfoliative dermatitis, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

**Other:** Anaphylaxis, angioedema, hyperkalemia, hyperuricemia, hyponatremia, lymphadenopathy

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm if given during the third trimester of pregnancy by increasing the risk of premature closure of the fetal ductus arteriosus.
- Drug should be avoided in pregnant women starting at 30 weeks of gestation.

### LACTATION

- Drug may be present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that NSAIDs like diclofenac should be avoided in patients with a recent MI because risk of reinfarction increases with NSAID therapy. If therapy is unavoidable, monitor patient closely for signs of cardiac ischemia.

- Be aware that the risk of heart failure increases with use of NSAIDs such as diclofenac. Diclofenac should not be given to patients with severe heart failure, but if unavoidable, monitor patient for worsening of heart failure.
- Use diclofenac with extreme caution and for shortest possible time in patients with a history of GI bleeding or ulcer disease because NSAIDs increase risk of GI bleeding and ulceration.
- Don't substitute one form of oral diclofenac for another. Different formulations aren't bioequivalent.
- Assess patient's hydration status before administering diclofenac intravenously because the patient must be well hydrated to reduce the risk of renal adverse reactions.
- Be aware that serious GI tract bleeding and ulceration, as well as perforation of intestine or stomach, can occur without warning or symptoms. Elderly patients are at greater risk. Monitor patient for signs of GI irritation and ulceration, especially if patient has a predisposing condition (such as a history of GI bleeding); takes an anticoagulant, NSAID (long-term), or oral corticosteroid; or has other factors such as being an alcoholic or smoker, has poor health, is over the age of 60; or tests positive for *Helicobacter pylori*. To minimize risk, give diclofenac with food. If patient develops GI distress, withhold drug and notify prescriber immediately.
- Use diclofenac cautiously in patients with hypertension, and monitor blood pressure closely; drug can cause or worsen hypertension.

**WARNING** Know that use of NSAIDs like diclofenac increases risk of serious cardiovascular thrombotic events, including MI and stroke, which can be life-threatening. These events may occur early in treatment and risk increases with duration of use. Be aware that these events have occurred even in patients who do not have a history of or risk factors for cardiovascular disease. Monitor patient for warning signs such as chest pain, shortness of breath, slurring of speech, or weakness. If any signs and symptoms develop, withhold diclofenac, alert prescriber immediately, and provide supportive care as prescribed.

- Report signs of bleeding, such as bleeding gums, bloody or cloudy urine, ecchymoses, melena, and petechiae. Know that risk of bleeding is

increased when patient is taking certain drugs like anticoagulants such as warfarin, antiplatelet agents such as aspirin, serotonin norepinephrine reuptake inhibitors, and serotonin reuptake inhibitors.

- Monitor BUN and serum creatinine levels in elderly patients, patients taking ACE inhibitors, ARDs, or diuretics, and patients with heart failure or impaired hepatic or renal function. These patients may have an increased risk of renal failure.
- Assess patient's skin routinely for rash or other signs of hypersensitivity reaction; drug may cause serious skin reactions without warning. At first sign of reaction, stop drug and notify prescriber.
- Know that because severe hepatic reactions may occur during diclofenac therapy, monitor liver enzymes and serum uric acid level as ordered. Liver enzyme elevations usually occur within 2 months of starting drug and should be reported promptly because dosage may need adjustment. Also monitor patient for evidence of hepatic dysfunction (diarrhea, fatigue, flu-like symptoms, jaundice, lethargy, nausea, pruritus, right upper quadrant tenderness).
- Report weight gain of more than 1 kg (2 lb) in 24 hours because it suggests fluid retention.

## **PATIENT TEACHING**

- Advise patient not to chew, crush, or dissolve tablet, but to swallow it whole.
- Tell patient prescribed Cambia brand to mix packet in 1 to 2 ounces of water, mix well, and drink immediately. Caution patient not to use any other liquids to mix the drug. Remind patient taking this form of diclofenac that taking it with food may decrease its effectiveness.
- Instruct patient to take diclofenac with food to minimize GI distress unless he is prescribed Zorvolex, which should be taken on an empty stomach.
- Instruct patient not to lie down for 15 to 30 minutes after taking drug to decrease risk of esophageal ulceration.
- Teach patient prescribed a topical system how to apply it. Tell patient if the topical system begins to peel-off, the edges may be taped down. If problems persist, patient may overlay the topical system with a mesh netting sleeve that allows air to pass through, where appropriate such as ankles, elbows, or knees. Stress importance of not applying topical system to damaged or nonintact skin. Also it should not be worn during bathing or showering. Warn patient not to use the topical system at the same time as taking an oral NSAID unless instructed to do so. Tell patient to wash

his hands after applying, handling or removing the topical system and to avoid eye contact.

- Teach patient prescribed a topical system how to apply it. Tell patient if the topical system begins to peel-off, the edges may be taped down. If problems persist, patient may overlay the topical system with a mesh netting sleeve that allows air to pass through, where appropriate such as ankles, elbows, or knees. Stress importance of not applying topical system to damaged or non-intact skin. Also it should not be worn during bathing or showering. Warn patient not to use the topical system at the same time as taking an oral NSAID unless instructed to do so. Tell patient to wash his hands after applying, handling or removing the topical system and to avoid eye contact.
- Warn patient to avoid hazardous activities until diclofenac's CNS effects are known.
- Urge patient to notify prescriber about dizziness, edema, impaired hearing, ringing or buzzing in ears, or unexplained weight gain.
- Advise patient to consult prescriber before taking aspirin or other OTC analgesics or drinking alcohol.
- Explain that diclofenac may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention for signs and symptoms such as chest pain, shortness of breath, slurred speech, and weakness.
- Inform patient that diclofenac therapy may increase risk of congestive heart failure. Instruct patient to promptly report to prescriber if edema, shortness of breath, or unexplained weight gain occurs.
- Tell patient that diclofenac also may increase risk of serious adverse GI reactions; stress need to seek immediate medical attention for such evidence as abdominal or epigastric pain, black or tarry stools, indigestion, and vomiting blood or material that looks like coffee grounds.
- Alert patient about possibly serious skin reactions and need to seek immediate medical attention for problems such as blisters, fever, itching, rash, and other signs of hypersensitivity such as difficulty breathing or swelling of face or throat.
- Urge patient to promptly report adverse liver effects (diarrhea, fatigue, flu-like symptoms, jaundice, lethargy, nausea, pruritus, right upper quadrant discomfort).
- Advise female patients to notify prescriber if pregnancy occurs or is suspected.
- Tell patient prescribed drug to treat migraine headaches not to overuse drug. Explain that this is because overuse, defined as using 10 or more

days per month, may lead to exacerbation of headache. Inform patient that overuse headache may appear as migraine-like daily headaches or as a marked increase in frequency of migraine attacks. If this occurs, tell patient to notify prescriber, as a withdrawal period may be needed.

## dicloxacillin sodium

### Class and Category

*Pharmacologic class:* Penicillinase-resistant penicillin

*Therapeutic class:* Antibiotic

### Indications and Dosages

- *To treat mild to moderate upper respiratory tract and localized skin and soft-tissue infections caused by penicillinase-producing staphylococci*

#### **CAPSULES, ORAL SOLUTION**

**Adults and children weighing 40 kg (88 lb) or more.**

125 mg every 6 hr.

**Children weighing less than 40 kg (less than 88 lb).**

12.5 mg/kg daily divided into four equal doses and given every 6 hr.

- *To treat severe infections, such as lower respiratory tract or disseminated infections, caused by penicillinase-producing staphylococci*

#### **CAPSULES, ORAL SOLUTION**

**Adults and children weighing 40 kg (88 lb) or more.**

250 mg every 6 hr, or higher doses, if needed. *Maximum:* 6

g daily.

**Children over age 1 month weighing less than 40 kg (less than 88 lb).** 25 mg/kg daily divided into 4 equal doses and given every 6 hr, or higher doses if needed.

## Mechanism of Action

Inhibits cell wall synthesis in susceptible bacteria, which assemble rigid, cross-linked cell walls in several steps. Dicloxacillin affects final cross-linking by inactivating penicillin-binding protein (the enzyme needed to link cell wall strands). This action inhibits cell wall synthesis and causes cell lysis and death.

## Contraindications

*Clostridium difficile* infection; hypersensitivity to dicloxacillin, other penicillins, beta-lactamase inhibitors or their components

## Interactions

### DRUGS

*aminoglycosides*: Inactivation of aminoglycosides

*oral contraceptives*: Decreased contraceptive action

*probenecid*: Increased and prolonged blood dicloxacillin level

*tetracyclines*: Decreased dicloxacillin effectiveness

*warfarin*: Reduced anticoagulant effect

### FOODS

*all foods*: Possibly delayed absorption

# Adverse Reactions

**CNS:** Dizziness, fatigue, fever, insomnia

**EENT:** Black “hairy” tongue, dry mouth, glossitis, **laryngeal edema**, **laryngospasm**, stomatitis, taste perversion

**GI:** Abdominal pain, anorexia, diarrhea, flatulence, nausea, **pseudomembranous colitis**, transient hepatitis, vomiting

**GU:** Nephropathy, vaginitis

**MS:** Prolonged muscle relaxation

**SKIN:** Dermatitis, **erythema multiforme**, pruritus, rash, urticaria, vesicular eruptions

**Other:** **Anaphylaxis**, serum sickness-like reaction, superinfection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Expect to obtain body fluid and tissue samples for culture and sensitivity tests, as ordered, and review the results, if possible, before dicloxacillin therapy begins. Also check for history of sensitivity to cephalosporins, penicillins, and other substances.
- Notify prescriber if diarrhea develops; it could be the development of pseudomembranous colitis.

## **PATIENT TEACHING**

- Instruct patient to take drug 1 hour before or 2 hours after meals.
- Instruct patient to take drug around the clock, not to miss a dose, and to complete the entire prescription unless directed otherwise by prescriber.
- Advise patient to take oral solution with a cold beverage but not acidic juice, such as orange juice. Explain that solution is effective for 7 days at room temperature and for 14 days if refrigerated.
- Caution patient not to open capsules and mix contents with food or liquids because an unpleasant taste and decreased drug absorption will result.
- Instruct patient to shake oral solution thoroughly and measure doses with a calibrated device for accuracy.
- Advise patient to notify prescriber if she experiences adverse GI reactions or signs of hypersensitivity or superinfection.
- Be aware that if patient takes an oral contraceptive, she should be advised to use an additional form of contraception during therapy.
- Instruct patient to store drug away from direct light, heat, and moisture and to refrigerate—but not freeze—oral solution.

**dicyclomine hydrochloride**

**Bentyl, Bentylol (CAN)**

## **Class and Category**

*Pharmacologic class: Anticholinergic*

*Therapeutic class: Antispasmodic*

## Indications and Dosages

➤ *To treat functional or irritable bowel syndrome*

### CAPSULES, SYRUP, TABLETS

**Adults.** *Initial:* 10 to 20 mg three to four times daily, increased as needed and tolerated after 1 wk to 40 mg four times daily. *Maximum:* 160 mg daily.

### SYRUP

**Children age 2 to 12 years.** 10 mg three to four times daily. *Maximum:* 40 mg daily.

**Infants and children age 6 months to 2 years.** 5 to 10 mg three to four times daily, 15 min before feeding. *Maximum:* 40 mg daily.

### I.M. INJECTION

**Adults.** 10 to 20 mg every 6 hr. Dosage adjusted as needed and tolerated but not given longer than 2 days.

## Mechanism of Action

Inhibits acetylcholine's muscarinic actions at postganglionic parasympathetic receptors in CNS, secretory glands, and smooth muscles. These actions relax smooth muscles and diminish biliary, GI, and GU tract secretions.

## Contraindications

Angle-closure glaucoma; breastfeeding; children less than 6 months old; GI obstruction; hemorrhagic shock; hypersensitivity to dicyclomine, other anticholinergic, or their components; ileus; myasthenia gravis; obstructive uropathy; reflux esophagitis; severe ulcerative colitis; toxic megacolon

## Interactions

### DRUGS

*adsorbent antidiarrheals, antacids:* Decreased dicyclomine absorption

*amantadine, antihistamines, antipsychotics such as phenothiazines, benzodiazepines, Class 1 antiarrhythmics such as quinidine, MAO inhibitors, narcotic analgesics such as meperidine, nitrates and nitrites, other anticholinergics, sympathomimetic agents, tricyclic antidepressants:*

Increased dicyclomine effects

*digoxin:* Increased risk of digitalis toxicity

*metoclopramide:* Decreased effect of metoclopramide on GI motility

*opioid analgesics:* Increased risk of ileus, severe constipation, and urine retention

## Adverse Reactions

**CNS:** Agitation, delirium, dizziness, drowsiness, dyskinesia, excitement, fever, insomnia, lethargy, light-headedness (I.M. use), nervousness, paresthesia, psychosis, syncope

**CV:** Palpitations, tachycardia

**EENT:** Blurred vision, cycloplegia, dry mouth, loss of taste, mydriasis, nasal congestion, photophobia

**GI:** Constipation, dysphagia, heartburn, ileus, vomiting

**GU:** Impotence, urine retention

**SKIN:** Decreased sweating, flushing, pruritus

**Other:** **Heatstroke**; injection-site pain, redness, and swelling

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Drug is contraindicated in women breastfeeding.

## Nursing Considerations

- Assess patient for tachycardia before giving dicyclomine; heart rate may increase.
- Don't give drug by I.V. route because major adverse reactions may occur.
- Watch for symptoms of hypersensitivity, such as agitation and pruritus. They usually resolve within 48 hours of stopping drug.
- Assess patient during long-term use for chronic constipation and fecal impaction, and take corrective measures, as prescribed.
- Monitor patient, especially the elderly and/or patients with mental illness, for delirium and psychosis. If present, notify prescriber and expect drug to be discontinued and symptoms to disappear within 12 to 24 hours.

### PATIENT TEACHING

- Instruct patient to store dicyclomine in a tightly sealed container at room temperature, protected from moisture and direct light. Advise her not to refrigerate syrup.
- Inform patient that dicyclomine relieves symptoms but doesn't cure the disorder.
- Instruct patient to take drug 30 to 60 minutes before eating.
- Advise patient not to take an antacid or an antidiarrheal within 2 hours of dicyclomine.
- Inform patient that blurred vision, dizziness, or drowsiness may occur.
- Advise patient to eat high-fiber foods and drink at least eight glasses of water daily to prevent constipation.

**WARNING** Urge patient to avoid getting overheated during exercise or in hot weather because heatstroke may result. Inform patient that hot baths or saunas may cause dizziness or fainting.

- Instruct patient to change position slowly to avoid light-headedness.
- Inform patient that stopping drug abruptly may cause dizziness and vomiting.
- Tell patient to take a missed dose as soon as she remembers, unless it's nearly time for the next dose. Caution against doubling the dose.
- Urge patient and family that if delirium or psychosis occurs, stop the drug and notify the prescriber. Inform them that these symptoms usually resolve within 12 to 24 hours after drug is discontinued.

## didanosine

### **Videx, Videx EC**

## **Class and Category**

*Pharmacologic class:* Nucleoside reverse transcriptase inhibitor (NRTI)

*Therapeutic class:* Antiretroviral

## Indications and Dosages

- *As adjunct to treat human immunodeficiency virus (HIV-1) infection*

### ORAL SOLUTION

**Adults weighing at least 60 kg (132 lb).** 200 mg twice daily. Alternative (but less preferred) dosing, 400 mg once daily.

**Adults weighing less than 60 kg (132 lb).** 125 mg twice daily. Alternative (but less preferred) dosing, 250 mg once daily.

**Children older than 8 months.** 120 mg/m<sup>2</sup> twice daily.

**Children 2 weeks to 8 months old.** 100 mg/m<sup>2</sup> twice daily.

### D.R. CAPSULES

**Adults and children weighing at least 60 kg (132 lb).** 400 mg once daily.

**Adults and children weighing 25 kg (55 lb) to less than 60 kg (132 lb).** 250 mg once daily.

**Children weighing 20 kg (44 lb) to less than 25 kg (55 lb).** 200 mg once daily.

### *DOSAGE ADJUSTMENT*

*For oral solution:* For adult patient with a creatinine clearance between 30 and 59 ml/min and weighing at least 60 kg (132 lb), dosage decreased to 100 mg twice daily or 200 mg once daily; for adult patient weighing less than 60 kg (132 lb), dosage decreased to 75 mg twice daily or 150 mg once daily. For adult patient with a creatinine clearance

between 10 and 29 ml/min and weighing at least 60 kg (132 lb), dosage decreased to 150 mg once daily; for adult patient weighing less than 60 kg (132 lb), dosage decreased to 100 mg once daily. For adult patient with a creatinine clearance less than 10 ml/min and weighing at least 60 kg (132 lb), dosage decreased to 100 mg once daily; for adult patient weighing less than 60 kg (132 lb), dosage decreased to 75 mg once daily. For pediatric patients with renal insufficiency, dosage reduced, but specific dose adjustment is unknown due to insufficient data.

*For D.R. capsules:* For adult patient with a creatinine clearance between 59 and 30 ml/min and weighing at least 60 kg (132 lb), dosage decreased to 200 mg once daily; for adult patient weighing less than 60 kg (132 lb), dosage decreased to 125 mg once daily. For adult patient with a creatinine clearance between 10 and 29 ml/min regardless of weight, dosage decreased to 125 mg once daily. For adult patient with a creatinine clearance less than 10 ml/min and weighing at least 60 kg, dosage also reduced to 125 mg once daily. Drug discontinued for patient with a creatinine clearance less than 10 ml/min and weighing less than 60 kg (132 lb). For pediatric patients with renal insufficiency, dosage reduced, but specific dose adjustment is unknown due to insufficient data.

*For adult patients taking tenofovir disoproxil fumarate concomitantly with either oral didanosine solution or D.R. didanosine capsules:* For patient with a creatinine clearance of at least 60 ml/min and weighing at least 60 kg (132 lb), dosage reduced to 250 mg once daily; for patient weighing less than 60 kg (132 lb), dosage reduced to 200 mg once daily. The appropriate dosage reduction for patients taking tenofovir disoproxil with creatinine clearance levels less than 60 ml/min is not established.

# Mechanism of Action

Inhibits the activity of HIV-1 reverse transcriptase in two ways. It competes with the natural substrate in the virus and it incorporates itself into the viral DNA causing termination of viral DNA chain elongation.

# Contraindications

Concomitant therapy with allopurinol, ribavirin, and stavudine; hypersensitivity to didanosine or its components

# Interactions

## DRUGS

*allopurinol, ganciclovir, ribavirin, tenofovir disoproxil fumarate*: Increased plasma didanosine concentration increasing risk for serious didanosine adverse reactions such as pancreatitis, peripheral neuropathy, and symptomatic hyperlactatemia/lactic acidosis

*antacids containing aluminum or magnesium*: Potential for increased adverse reactions associated with antacids, such as constipation and diarrhea

*azole antifungals (ketoconazole, itraconazole). quinolone antibiotics, tetracycline antibiotics*: Potential for decreased concentration of these drugs

*ciprofloxacin, delavirdine, indinavir*: Decreased plasma levels of these drugs with potential for decreased effectiveness

*drugs that may cause pancreatic toxicity*: Potential for increased risk of pancreatitis

*hydroxyurea*: Potential for increased risk of fatal hepatotoxicity, pancreatitis, or severe peripheral neuropathy

*methadone*: Decreased plasma didanosine concentrations with potential for decreased effectiveness

*neurotoxic drugs*: Potential for increased risk of neuropathy

*stavudine*: Increased risk of fatal lactic acidosis in pregnant women

## ACTIVITIES

*alcohol use*: Possibly increased risk of liver dysfunction

## Adverse Reactions

**CNS**: Asthenia, chills, fever, headache, peripheral neuropathy

**EENT**: Dry eyes or mouth, inflamed salivary glands, optic neuritis, parotid gland enlargement, retinal changes

**ENDO**: Hyperglycemia, **hypoglycemia**

**GI**: Abdominal pain, anorexia, diarrhea, dyspepsia, elevated liver or pancreatic enzymes, flatulence, **hepatic toxicity**, **hepatitis**, **liver failure**, nausea, **non-cirrhotic portal hypertension**, **pancreatitis**, **severe hepatomegaly with steatosis**, vomiting

**GU**: **Acute renal failure**

**HEME**: Anemia, **leukopenia**, **thrombocytopenia**

**MS**: Arthralgia, myalgia, myopathy, **rhabdomyolysis**

**SKIN**: Alopecia, rash

**Other**: **Anaphylaxis**, generalized pain, **hyperlactatemia**, hyperuricemia, **lactic acidosis**

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.

- Drug may cause fetal harm such as congenital malformations.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Drug is contraindicated when used in conjunction with stavudine because of increased risk for fatal lactic acidosis in pregnant women.

## LACTATION

- It is not known if drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## Nursing Considerations

- Use didanosine with extreme caution in patients with risk factors for pancreatitis such as advanced HIV infection or renal impairment and in the elderly. Be aware that the use of didanosine with stavudine is contraindicated because the combination increases risk of pancreatitis. Know that the frequency of pancreatitis is dose related. Monitor patient for signs and symptoms of pancreatitis throughout therapy. Be aware that drug must be discontinued if pancreatitis is confirmed.
- Use didanosine cautiously in patients with known risk factors for liver disease. Be aware that the combined use of didanosine with hydroxyurea and stavudine is contraindicated because this combination has resulted in the highest number of fatal hepatic events. Monitor patient and liver enzymes for evidence of liver disease throughout therapy. If liver disease develops or becomes worse, expect drug to be discontinued and supportive care given.
- Administer didanosine on an empty stomach at least 30 minutes before or 2 hours after patient has eaten.

**WARNING** Know that lactic acidosis and severe hepatomegaly with steatosis have occurred with didanosine therapy, and death has occurred in some patients. Fatal lactic acidosis has been reported in pregnant women who received the combination of didanosine and stavudine

with other antiretrovirals. Risk factors include presence of obesity, prolonged nucleoside exposure, and being female. However, know that lactic acidosis and severe hepatomegaly with steatosis have also occurred in patients with no known risk factors. Expect drug to be discontinued in any patient who develops clinical or laboratory findings suggestive of lactic acidosis or pronounced hepatotoxicity, even in the absence of marked transaminase elevations.

- Monitor patient for early signs of portal hypertension such as the presence of splenomegaly accompanied by thrombocytopenia, because didanosine has been linked to non-cirrhotic portal hypertension. Expect to monitor the patient with the following laboratory tests: complete blood count, international normalized ratio, liver enzymes, and serum albumin and bilirubin levels. Ultrasonography may be warranted as well. If confirmed, expect didanosine therapy to be discontinued.
- Assess patient for signs and symptoms of peripheral neuropathy such as complaints of numbness, pain, or tingling in the feet or hands. Risk factors for developing didanosine-related peripheral neuropathy include advanced HIV disease, history of neuropathy, or being treated with neurotoxic therapy. Report such complaints to prescriber, as drug may have to be discontinued.
- Ensure that patient has periodic retinal examinations while receiving didanosine, because drug may cause optic neuritis and retinal changes.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including didanosine. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.

## PATIENT TEACHING

- Instruct patient to take didanosine exactly as prescribed. If a dose is missed, instruct patient to take it as soon as possible. Stress importance of taking drug on a regular schedule and not missing doses, if possible, to avoid the development of resistance to the drug.

- Tell patient to take drug on an empty stomach, at least 30 minutes before or 2 hours after eating.
- Warn patient to alert all prescribers of didanosine therapy, because drug may cause serious interactions with some other drugs. Also tell patient not to take any over-the-counter preparations, including herbal products, without consulting prescriber first.
- Stress importance of reporting persistent, severe, or unusual signs and symptoms to prescriber, because serious adverse reactions can occur with didanosine, especially affecting the liver and pancreas. Also stress the need to report any numbness, pain, or tingling in patient's feet or hands.
- Caution patient to be compliant with laboratory monitoring for early detection of adverse reactions associated with didanosine use.
- Inform patient to report any changes in vision, especially blurred vision, to prescriber. Stress importance of having regular eye examinations when taking didanosine.
- Tell patient to immediately report any symptoms of infections to prescriber.
- Inform patient that loss of body fat from his arms, face, or legs may occur while taking didanosine.
- Instruct patient to avoid alcohol while taking didanosine.
- Tell women of childbearing age to alert prescriber if pregnancy is suspected or known. If confirmed, encourage patient to register with the antiretroviral pregnancy registry that monitors fetal outcomes of pregnant women exposed to didanosine.
- Warn mothers with HIV infection not to breastfeed the infant, because the HIV-1 virus can be passed to the baby in breast milk.

## digoxin

### **Lanoxin, Lanoxin Pediatric**

## **Class and Category**

*Pharmacologic class:* Cardiac glycoside

*Therapeutic class:* Antiarrhythmic, cardiotonic

## Indications and Dosages

- *To treat mild to moderate heart failure with rapid digitalization*

### I.V. INJECTION

**Adults and children over age 10.** *Loading:* 8 to 12 mcg/kg in 3 divided doses, with first dose equal to 50% of total dose and 25% of the total loading dose every 6 to 8 hr for two doses. I.V. injection given slowly over 5 min or longer. Subsequent doses given every 6 to 8 hr.

*Maintenance:* 2.4 to 3.6 mcg/kg once daily.

**Children ages 5 to 10.** *Loading:* 15 to 30 mcg/kg in 3 divided doses, with first dose equal to 50% of total dose and 25% of the total loading dose given every 6 to 8 hr for two doses. I.V. injection given over 5 min or longer.

*Maintenance:* 2.3 to 4.5 mcg/kg twice daily.

**Children ages 2 to 5.** *Loading:* 25 to 35 mcg/kg in 3 divided doses, with first dose equal to 50% of total dose and 25% of the total loading dose given every 6 to 8 hr for two doses. I.V. injection given slowly over 5 min or longer.

*Maintenance:* 3.8 to 5.3 mcg/kg twice daily.

**Infants ages 1 to 24 months.** *Loading:* 30 to 50 mcg/kg in 3 divided doses, with first dose equal to 50% of total dose and 25% of the total loading dose given every 6 to 8 hr for two doses. I.V. injection given slowly over 5 min or longer. *Maintenance:* 4.5 to 7.5 mcg/kg twice daily.

**Full-term neonates.** *Loading:* 20 to 30 mcg/kg in 3 divided doses, with first dose equal to 50% of total dose and 25% of total loading dose given every 6 to 8 hr for two

doses. I.V. injection given slowly over 5 min or longer.

*Maintenance:* 3 to 4.5 mcg/kg twice daily.

**Premature neonates.** *Loading:* 15 to 25 mcg/kg in 3 divided doses, with first dose equal to 50% of total dose and 25% of the total loading dose given every 6 to 8 hr for two doses. I.V. injection given slowly over 5 min or longer. *Maintenance:* 1.9 to 3.1 mcg/kg twice daily.

## **ORAL SOLUTION, TABLETS**

**Adults and children over age 10.** *Loading:* 10 to 15 mcg/kg total given in 3 divided doses every 6 to 8 hr, with first dose equal to 50% of total dose and subsequent two doses given each as 25% of the total loading dose.

*Maintenance:* 3.4 to 5.1 mcg/kg once daily.

**Children ages 5 to 10.** *Loading:* 20 to 45 mcg/kg in 3 divided doses every 6 to 8 hr and subsequent two doses given each as 25% of the total loading dose. *Maintenance:* 3.2 to 6.4 mcg/kg daily in 2 divided doses.

## **ORAL SOLUTION**

**Children ages 2 to 5.** *Loading:* 30 to 45 mcg/kg in 3 divided doses every 6 to 8 hr, with first dose equal to 50% of total dose and each of remaining two doses equal to 25% of total dose. *Maintenance:* 7.5 to 10 mcg/kg daily in 2 divided doses.

**Infants ages 1 to 24 months.** *Loading:* 35 to 60 mcg/kg in 3 divided doses every 6 to 8 hr, with first dose equal to 50% of total dose and each of remaining two doses equal to 25% of total dose. *Maintenance:* 10 to 15 mcg/kg daily in 2 divided doses.

**Full-term neonates.** *Loading:* 25 to 35 mcg/kg in 3 divided doses every 6 to 8 hr, with first dose equal to 50% of total dose and each of remaining two doses equal to 25%

of total dose. *Maintenance*: 6 to 10 mcg/kg daily in 2 divided doses.

**Premature neonates.** *Loading*: 20 to 30 mcg/kg in 3 divided doses every 6 to 8hr, with first dose equal to 50% of total dose and each of remaining two doses equal to 25% of total dose. *Maintenance*: 5 to 7.5 mcg/kg daily in 2 divided doses.

➤ *To control ventricular response rate in chronic atrial fibrillation*

## ORAL SOLUTION TABLETS

**Adults.** *Loading*: 10 to 15 mcg/kg in 3 divided doses every 6 to 8 hr, with first dose equal to 50% of total loading dose and each of remaining two doses given as 25% of total loading dose. *Maintenance*: 3.4 to 5.1 mcg/kg once daily for tablets and 3.0 to 4.5 mcg/kg once daily for elixir.

## I.V. INJECTION

**Adults.** *Initial*: 8 to 12 mcg/kg every 6 to 8 hr, with first dose equal to 50% of total loading dose and each of remaining two doses given as 25% of total loading dose. *Maintenance*: 2.4 to 3.6 mcg/kg once daily. I.V. injection given slowly over 5 min or longer.

**DOSAGE ADJUSTMENT** Dosage carefully adjusted for patients who are debilitated or elderly or have implanted pacemakers because toxicity may develop at doses tolerated by most patients.

Route	Onset	Peak	Duration
P.O.	30-120 min	6-8 hr	3-4 days
I.V.	5-30 min	1-5 hr	3-4 days

## Mechanism of Action

Increases the force and velocity of myocardial contraction, resulting in positive inotropic effects. Digoxin produces antiarrhythmic effects by decreasing the conduction rate and increasing the effective refractory period of the AV node.

## Contraindications

Hypersensitivity to digoxin or its components, presence of digitalis toxicity, ventricular fibrillation ventricular tachycardia unless heart failure occurs unrelated to digoxin therapy

## Interactions

### DRUGS

*amiodarone, mirabegron, propafenone, quinine, spironolactone, quinine, spironolactone, verapamil:*

Increased digoxin concentration up to 50%, increasing risk of digitalis toxicity

*beta blockers, calcium channel blockers:* Increased additive effects of slowing heart rate, possibly producing bradycardia

*calcium supplements given rapidly I.V.:* Increased risk of serious arrhythmias

*dofetilide:* Increased risk for torsades de pointes

*dronedarone:* Increased risk of sudden death

*ivabradine:* Increased risk of bradycardia

*nephrotoxic drugs:* Increased risk of digitalis toxicity

*neuromuscular blocking agents such as succinylcholine:* Possibly sudden release of potassium from muscle cells increasing risk of arrhythmias

*quinidine, ritonavir:* Increased digoxin concentration by more than 50%, significantly increasing risk of digitalis

toxicity

*sotalol*: Increased risk of proarrhythmias

*sympathomimetics*: Increased risk of arrhythmias

*teriparatide*: Transiently increases serum calcium which may cause digitalis toxicity

*thyroid hormone*: Decreased plasma digoxin level, requiring an increase in dosage

## FOODS

*high-fiber food*: Decreased oral digoxin absorption

## Adverse Reactions

**CNS**: Confusion, depression, drowsiness, extreme weakness, headache, syncope

**CV**: **Arrhythmias**, **heart block**

**EENT**: Blurred vision, colored halos around objects

**GI**: Abdominal discomfort or pain, anorexia, diarrhea, nausea, vomiting

**Other**: **Electrolyte imbalances**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm but drug does cross placenta.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Dosage may need to be increased during pregnancy and decreased in the postpartum period.
- Upon birth, neonates should be monitored for signs and symptoms of digoxin toxicity.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that digoxin therapy is not recommended in patients with acute cor pulmonale involving heart failure associated with amyloid heart disease, constrictive pericarditis, preserved left ventricular ejection fraction, or restrictive cardiomyopathy because of increased susceptibility to digoxin toxicity. The drug is also not recommended in patients with idiopathic hypertrophic subaortic stenosis because outflow obstruction may worsen because of the inotropic effects of digoxin.
- Expect to treat underlying thiamine deficiency in patients with beri-beri heart disease because if left untreated, digoxin therapy may be ineffective.
- Give parenteral digoxin undiluted, or dilute with a fourfold or greater volume of sterile water for injection, normal saline solution, or D<sub>5</sub>W for I.V. administration. Once diluted, give immediately over 5 minutes or longer. Discard if solution is markedly discolored or contains precipitate.
- Take patient's apical pulse before giving each dose and notify prescriber if it's below 60 beats/minute (or other specified level).
- Monitor patient closely for signs of digitalis toxicity, such as altered mental status, arrhythmias, heart block, nausea, vision disturbances, and vomiting. If they appear, notify prescriber, check serum digoxin level as ordered, and expect to withhold drug until level is known. Monitor ECG tracing continuously.
- Be aware that because digoxin has a narrow therapeutic index and interacts with many different drugs, monitoring of serum digoxin levels is important when other drugs are prescribed or discontinued or dosages adjusted.
- Assess for drug effectiveness if patient has acute or unstable chronic atrial fibrillation. Ventricular rate may not normalize even when serum drug level falls within therapeutic range; raising the dosage probably won't produce a therapeutic effect and may lead to toxicity.
- Obtain frequent ECG tracings as ordered in elderly patients because of their smaller body mass and reduced renal clearance. Elderly patients,

especially those with coronary insufficiency, are more susceptible to arrhythmias—particularly ventricular fibrillation—if digitalis toxicity occurs.

- Monitor patient's serum potassium level regularly because hypokalemia predisposes to digitalis toxicity and serious arrhythmias. Also monitor potassium level often when giving potassium salts because hyperkalemia in patients receiving digoxin can be fatal.
- Be aware that digoxin requirements may increase during pregnancy and decrease in the postpartum period. Expect digoxin levels to be monitored closely during pregnancy and the postpartum period. Also be aware that digoxin does cross the placenta. Monitor neonates of mothers taking digoxin during pregnancy for signs and symptoms of digoxin toxicity, including arrhythmias and vomiting.

## **PATIENT TEACHING**

- Emphasize importance of taking digoxin exactly as prescribed. Warn about possible toxicity from taking too much and decreased effectiveness from taking too little.
- Instruct patient to take digoxin at same time each day to help increase compliance.
- Teach patient how to take her pulse, and instruct her to do so before each dose. Urge her to notify prescriber if pulse falls below 60 beats/minute or suddenly increases.
- Inform patient that small, white 0.25-mg tablets can easily be confused with other drugs. Caution against carrying digoxin in anything other than its original labeled container.
- Emphasize need to use special dropper supplied with elixir to ensure accurate dose measurement.
- Instruct patient to take a missed dose as soon as she remembers if within 12 hours of scheduled dose. If not, urge her to notify prescriber immediately.
- Urge patient to notify prescriber if she experiences adverse reactions, such as GI distress or pulse changes.
- Instruct patient to carry medical identification that indicates her need for digoxin.
- Advise patient to consult prescriber before using other drugs, including OTC products.

# digoxin immune Fab (ovine)

## DigiFab

### Class and Category

*Pharmacologic class:* Antibody fragment

*Therapeutic class:* Cardiac glycoside antidote

### Indications and Dosages

- *To treat acute life-threatening digoxin or digitoxin toxicity*

#### I.V. INFUSION, I.V. INJECTION

**Adults with unknown amount of ingestion.** *Initial:* 400 mg (10 vials) with a second dose of 400 mg (10 vials) given, if needed. I.V. infusion given slowly over at least 30 minutes, with I.V. injection reserved for use if cardiac arrest is imminent and given as a bolus.

**Adults, children, and infants with known amount ingested.** Highly individualized based on number of capsules or tablets ingested or the postdistribution serum drug level is known. I.V. infusion given slowly over at least 30 min, with I.V. injection reserved for use if cardiac arrest is imminent and given as a bolus.

***DOSAGE ADJUSTMENT*** Higher dose administered, as prescribed, if the dose based on ingested amount differs substantially from the dose based on serum digoxin or digitoxin level. Dose repeated after several hours, if needed.

Route	Onset	Peak	Duration
I.V.	15-30 min	Unknown	8-12 hr

## Mechanism of Action

Binds with digoxin or digitoxin molecules. The resulting complex is excreted through the kidneys. As the free-serum digoxin level declines, tissue-bound digoxin enters the serum and also is bound and excreted.

## Contraindications

Hypersensitivity to digoxin immune Fab or its components

## DRUGS

None reported

## Adverse Reactions

**CV:** Increased ventricular rate (in atrial fibrillation), worsening of heart failure or low cardiac output

**Other:** Allergic reaction, febrile reaction, hypokalemia

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding after having received the drug.

## Nursing Considerations

- Expect each 38-mg vial of purified digoxin immune Fab to bind about 0.5 mg of digoxin or digitoxin.
- Reconstitute for I.V. use by dissolving 40 mg in 4 ml of sterile water for injection to yield 10 mg/ml. Mix gently. Further dilute with normal saline solution to proper volume for I.V. infusion. For very small doses, reconstituted 40-mg vial may be diluted with 36 ml of normal saline solution to yield 1 mg/ml.

**WARNING** Monitor patient for an acute allergic reaction (angioedema, bronchospasm with cough or wheezing, erythema, hypotension, laryngeal edema, pruritus, stridor, tachycardia, or urticaria). If an anaphylactic reaction occurs during infusion, stop administration. Expect to treat all allergic reactions according to protocol. Be aware that patients with a history of hypersensitivity to papaya or papain are at high risk for an allergic reaction; digoxin immune Fab should be administered to this patient only if the benefits outweigh the risks. Also know that prior treatment with digoxin-specific Fab might increase the risk of diminished effects of the drug.

- Know that for an infant, reconstitute digoxin immune Fab as ordered and administer with a tuberculin syringe.
- Watch for fluid volume overload when administering drug to an infant or small child.
- Be aware that when giving a large dose, expect a faster onset but watch closely for febrile reaction.
- Give I.V. infusion through a 0.22-micron membrane filter slowly over at least 30 minutes. Keep in mind that drug may be given by rapid I.V.

injection if cardiac arrest is imminent.

- Monitor serum potassium level often, especially during first few hours of therapy. Potassium level may drop rapidly.

## PATIENT TEACHING

- Inform patient of the purpose of digoxin immune Fab and how it will be given.
- Advise patient to immediately report any signs and symptoms associated with an allergic reaction.

## dihydroergotamine mesylate

**D.H.E. 45, Dihydroergotamine-  
Sandoz (CAN), Migranal**

## Class and Category

*Pharmacologic class:* Ergot alkaloid

*Therapeutic class:* Antimigraine

## Indications and Dosages

➤ *To treat acute migraine with or without aura*

### I.M. INJECTION, SUBCUTANEOUS INJECTION

**Adults.** 1 mg at first sign of headache, repeated every hour up to 3 mg, if needed. *Maximum:* 3 mg/24 hr, 6 mg/wk.

## I.V. INJECTION

**Adults.** 1 mg, repeated in 1 hr, if needed. *Maximum:* 2 mg/24 hr, 6 mg/wk.

## NASAL SPRAY (MIGRANAL)

**Adults.** 1 spray (0.5 mg) in each nostril, repeated in 15 min for a total dose of 2 sprays in each nostril or 2 mg.

*Maximum:* 3 mg/24 hr, 4 mg/wk.

➤ *To treat acute episodes of cluster headaches*

## I.M. INJECTION, SUBCUTANEOUS INJECTION

**Adults.** 1 mg at first sign of headache, repeated every hour up to 3 mg, if needed. *Maximum:* 3 mg/24 hr, 6 mg/wk.

## I.V. INJECTION

**Adults.** 1 mg at first sign of headache, repeated in 1 hr, if needed. *Maximum:* 2 mg/24 hr, 6 mg/wk.

Route	Onset	Peak	Duration
I.V.	In 5 min	15 min-2 hr	About 8 hr
I.M., SubQ	15-30 min	15 min-2 hr	3-4 hr
Nasal	In 30 min	30-60 min	Unknown

## Mechanism of Action

Produces intracranial and peripheral vasoconstriction by binding to all known 5-hydroxytryptamine<sub>1</sub> (5-HT<sub>1</sub>) receptors, alpha<sub>1</sub>- and alpha<sub>2</sub>-adrenergic receptors, and dopaminergic receptors. Activation of 5-HT<sub>1</sub> receptors on intracranial blood vessels probably constricts large intracranial arteries and closes arteriovenous anastomoses

to relieve cluster and migraine headaches. Activation of 5-HT<sub>1</sub> receptors on sensory nerves in the trigeminal system also may inhibit the release of proinflammatory neuropeptides.

Peripherally, dihydroergotamine causes vasoconstriction by stimulating alpha-adrenergic receptors. At therapeutic doses, it inhibits norepinephrine reuptake, increasing vasoconstriction. Drug constricts veins more than arteries, increasing venous return while decreasing venous stasis and pooling.

## Contraindications

Basilar or hemiplegic headaches; breastfeeding; concurrent use with central and peripheral vasoconstrictors; coronary artery disease, including vasospasm; hypersensitivity to dihydroergotamine, other ergot alkaloids, or their components; ischemic heart disease; peripheral arterial vascular disease or after vascular surgery; pregnancy; sepsis; severe hepatic or renal impairment; uncontrolled hypertension; use of macrolide antibiotics or protease inhibitors; use within 24 hours of 5-HT<sub>1</sub> agonist, ergotamine-containing or ergot-type drug, or methysergide

## Interactions

### DRUGS

*beta blockers*: Possibly peripheral vasoconstriction and peripheral ischemia, increased risk of gangrene

*macrolides, protease inhibitors*: Possibly increased risk of vasospasm, acute ergotism with peripheral ischemia

*other ergot drugs, including ergoloid mesylates, ergonovine, methylergonovine, methysergide, and*

*sumatriptan*: Increased risk of serious adverse effects including coronary artery vasospasm  
*peripheral vasoconstrictors*: Risk of severe hypertension  
*selective serotonin reuptake inhibitors such as fluoxetine, vluvoxamine, paroxetine, sertraline*: Increased risk of hyperreflexia, incoordination, and weakness

## ACTIVITIES

*smoking*: Possibly increased ischemic response to ergot therapy

## Adverse Reactions

**CNS**: Anxiety, confusion, dizziness, fatigue, headache, paresthesia, somnolence, weakness

**CV**: **Bradycardia**, chest pain, peripheral vasospasm, tachycardia

**EENT**: Abnormal vision; dry mouth; epistaxis, nasal congestion or rhinitis, and sore nose (nasal spray); miosis; pharyngitis; sinusitis; taste perversion

**GI**: Diarrhea, nausea, vomiting

**MS**: Muscle stiffness

**SKIN**: Localized edema of face, feet, fingers, and lower legs; sensation of heat or warmth; sudden diaphoresis

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Drug is contraindicated during pregnancy.

## LACTATION

- Drug may be present in breast milk and may cause diarrhea, unstable blood pressure, vomiting, or weak pulse in breastfed infants.
- Drug is contraindicated in women who are breastfeeding.

## Nursing Considerations

**WARNING** Monitor patient for signs of dihydroergotamine overdose, such as abdominal pain, confusion, delirium, dizziness, dyspnea, headache, nausea, pain in legs or arms, paresthesia, seizures, and vomiting.

- Assess patient's capillary refill, peripheral pulses, and skin sensation and warmth. After giving nasal dihydroergotamine, monitor patient for signs of widespread blood vessel constriction and adverse reactions caused by decreased circulation to many body areas.

## PATIENT TEACHING

- Instruct patient to use nasal spray or give self a subcutaneous injection, if prescribed, when headache pain—not aura—begins.
- Teach her to prime spray pump by squeezing it four times.
- Advise patient to wait 15 minutes between each set of nasal sprays.
- Teach patient prescribed drug via subcutaneous route how to administer injection and how to properly dispose of needles.
- Encourage patient to lie down in a quiet, dark room after using drug.
- Instruct patient to use more dihydroergotamine if headache returns or worsens but not to exceed maximum prescribed amount or frequency.
- Remind patient to take drug only as needed, not on a daily basis.
- Instruct patient to discard residual nasal spray in an open ampule after 8 hours.
- Caution her not to use dihydroergotamine and to notify prescriber if she experiences a different type of headache than drug prescribed to treat.

- Inform patient that nasal drug won't relieve pain other than throbbing headaches.
- Advise patient to avoid alcohol, which can cause or worsen headaches, and to avoid smoking, which may cause an ischemic response.

## diltiazem hydrochloride

**Apo-Diltiaz (CAN), Cardizem, Cardizem CD, Cardizem LA, Cartia XL, Dilacor XR, Dilt-CD, Diltzac, Taztia XT, Tiazac ER**

### Class and Category

*Pharmacologic class:* Calcium channel blocker

*Therapeutic class:* Antianginal, antiarrhythmic, antihypertensive

### Indications and Dosages

- *To treat chronic stable angina and angina due to coronary artery spasm*

#### **TABLETS**

**Adults.** *Initial:* 30 mg four times daily before meals and at bedtime, increased every 1 or 2 days as needed. *Maximum:* 360 mg daily in divided doses three times daily or four times daily.

## Mechanism of Action

Diltiazem inhibits calcium movement into coronary and vascular smooth-muscle cells by blocking slow calcium channels in cell membranes, as shown. This action decreases intracellular calcium, which:

- inhibits smooth-muscle cell contractions
- decreases myocardial oxygen demand by relaxing coronary and vascular smooth muscle, reducing peripheral vascular resistance and systolic and diastolic blood pressures
- slows AV conduction time and prolongs AV nodal refractoriness
- interrupts the reentry circuit in AV nodal reentrant tachycardias.

## E.R. CAPSULES OR TABLETS

**Adults.** *Initial:* 120 mg or 180 mg daily, increased every 7 to 14 days as needed. *Maximum:* 360 mg daily (Cardizem LA), 480 mg (Cardizem CD, Cartia XT, or Dilacor XR), and 540 mg (Taztia XT, Tiazac).

- *To improve exercise tolerance in patients with chronic stable angina*

## E.R. TABLETS (CARDIZEM LA)

**Adults.** *Initial:* 180 mg once daily, increased in 7 to 14 days, as needed. *Maximum:* 360 mg daily.

- *To control hypertension*

## **E.R. CAPSULES**

**Adults. and adolescents.** *Initial:* 120 to 240 mg daily, increased in 7 to 14 days. *Maximum:* 480 mg daily (Cardizem CD) 540 mg daily (Tiazac).

## **E.R. TABLETS**

**Adults.** *Initial:* 180 to 240 mg daily, increased after 14 days, as needed. *Maximum:* 540 mg daily.

- *To treat atrial fibrillation, atrial flutter, and paroxysmal supraventricular tachycardia*

## **I.V. INFUSION OR INJECTION**

**Adults.** 0.25 mg/kg given by bolus over 2 min. If response is inadequate after 15 min, 0.35 mg/kg given by bolus over 2 min. Then 5 or 10 mg/hr after bolus, increased by 5 mg/hr, as needed. *Maximum:* 15 mg/hr for up to 24 hr.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.	30-60 min	In 2 wk	Unknown
P.O. (E.R.)	2-3 hr	In 2 wk	Unknown
I.V.	In 3 min	2-7 min	30 min-10 hr*

\* For infusion; 1 to 3 hr for injection.

## **Incompatibilities**

Don't give diltiazem through same I.V. line as acetazolamide, acyclovir, aminophylline, ampicillin sodium/sulbactam sodium, cefamandole, cefoperazone, diazepam, furosemide, heparin, hydrocortisone sodium succinate, methylprednisolone sodium succinate,

mezlocillin, nafcillin, phenytoin, rifampin, or sodium bicarbonate.

## Contraindications

Acute MI; cardiogenic shock (I.V. administration); Lown-Ganong-Levine or Wolff-Parkinson-White syndrome (I.V. administration), second- or third-degree AV block, or sick sinus syndrome, unless artificial pacemaker is in place; pulmonary edema; systolic blood pressure below 90 mm Hg; ventricular tachycardia (wide complex) (I.V. administration); within a few hours of I.V. beta-blocker therapy (I.V. administration)

## Interactions

### DRUGS

*anesthetic*: Additive hypotension; possibly decreased cardiac contractility, conductivity, and automaticity

*benzodiazepines*: Increased risk of prolonged sedation

*beta blockers*: Possibly increased risk of adverse cardiovascular effects, especially AV block and bradycardia

*bupirone*: Increased effects and risk of bupirone toxicity

*carbamazepine, quinidine*: Decreased hepatic clearance and increased serum levels of these drugs, leading to toxicity

*cimetidine*: Decreased diltiazem metabolism, increased blood diltiazem level

*clonidine*: Increased risk of serious sinus bradycardia

*cyclosporine*: Possibly increased cyclosporine levels

*digoxin*: Increased blood digoxin level; increased risk of AV block or bradycardia

*ivabradine*: Increased ivabradine exposure which may exacerbate bradycardia and conduction disturbances

*rifampin*: Decreased blood diltiazem level to undetectable amounts

*statins*: Increased blood statin level with increased risk of myopathy and rhabdomyolysis

## Adverse Reactions

**CNS:** Abnormal gait, amnesia, asthenia, depression, dizziness, dream disturbances, extrapyramidal reactions, fatigue, hallucinations, headache, insomnia, nervousness, paresthesia, personality change, somnolence, syncope, tremor, weakness

**CV:** Angina, **atrial flutter**, **AV block**, **bradycardia**, bundle-branch block, **ECG abnormalities**, **heart failure**, **hypotension**, palpitations, peripheral edema, **PVCs**, **sinus arrest**, sinus tachycardia, **ventricular fibrillation**, **ventricular tachycardia**

**EENT:** Amblyopia, dry mouth, epistaxis, eye irritation, gingival bleeding and hyperplasia, gingivitis, nasal congestion, retinopathy, taste perversion, tinnitus

**ENDO:** Hyperglycemia

**GI:** Anorexia, constipation, diarrhea, elevated liver enzymes, indigestion, nausea, thirst, vomiting

**GU:** **Acute renal failure**, impotence, nocturia, polyuria, sexual dysfunction

**HEME:** **Hemolytic anemia**, **leukopenia**, **prolonged bleeding time**, **thrombocytopenia**

**MS:** Arthralgia, muscle spasms, myalgia

**RESP:** Cough, dyspnea

**SKIN:** Acute generalized exanthematous pustulosis, alopecia, diaphoresis, **erythema multiforme**, **exfoliative**

**dermatitis**, flushing, leukocytoclastic vasculitis, petechiae, photosensitivity, pruritus, purpura, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Angioedema**, hyperuricemia, weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Use diltiazem cautiously in patients with impaired hepatic or renal function, and monitor liver and renal function, as appropriate; drug is metabolized mainly in the liver and excreted by the kidneys.

**WARNING** Monitor patient's blood pressure, heart rate and rhythm by continuous ECG, and pulse rate as appropriate during therapy. Keep emergency equipment and drugs available.

- Assess patient for signs and symptoms of heart failure.
- Watch for digitalis toxicity (nausea, vomiting, and visual color distortion) if patient takes digoxin and has an elevated serum digoxin level.

- Administer sublingual nitroglycerin, as prescribed, during diltiazem therapy.
- Expect to discontinue drug if adverse skin reactions, usually transient, persist although some may be severe.

## PATIENT TEACHING

- Explain that capsules and E.R. tablets must be swallowed whole.

**WARNING** Tell patient that stopping drug suddenly may have life-threatening effects.

- Advise patient to monitor blood pressure and pulse rate regularly and to report significant changes to prescriber.
- Urge patient to report chest pain, difficulty breathing, dizziness, fainting, irregular heartbeat, rash, or swollen ankles.
- Instruct patient to maintain good oral hygiene, perform gum massage, and see a dentist every 6 months to prevent gingival bleeding and hyperplasia and gingivitis.
- Inform all prescribers of diltiazem therapy. Tell patient to consult prescriber before taking any OTC medication.
- Tell patient to inform prescriber if pregnancy occurs or is suspected.

## diphenhydramine hydrochloride

**Allerdryl (CAN), Benadryl,  
Diphenhist, Nytol, Siladryl, Siphen,  
Sominex Unisom**

# Class and Category

*Pharmacologic class:* Antihistamine

*Therapeutic class:* Antianaphylactic adjunct, antidyskinetic, antiemetic, antihistamine, antitussive (syrup), antivertigo, sedative-hypnotic

## Indications and Dosages

- *To treat hypersensitivity reactions, such as perennial and seasonal allergic rhinitis, vasomotor rhinitis, allergic conjunctivitis, uncomplicated allergic skin eruptions, and transfusion reactions; to prevent or treat motion sickness*

### **CAPSULES, CHEWABLE TABLETS, ELIXIR, ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS**

**Adults and adolescents.** 25 to 50 mg three or four times daily, as needed. *Maximum:* 300 mg daily.

**Children weighing over 9 kg (20 lb).** 12.5 to 25 mg three or four times daily, as needed. Alternatively, 5 mg/kg/24 hr. *Maximum:* 300 mg daily.

### **ELIXIR**

**Adults and adolescents.** 25 to 50 mg every 4 to 6 hr, as needed. *Maximum:* 300 mg daily.

**Children.** 1.25 mg/kg every 4 to 6 hr. *Maximum:* 300 mg daily.

### **I.V. OR I.M. INJECTION**

**Adults and adolescents.** 10 to 50 mg, not to exceed 25 mg/min I.V. or per I.M. site, up to 100 mg/dose, as needed.

*Maximum:* 400 mg daily.

**Children other than premature infants and neonates.**

1.25 mg/kg, 5 mg/kg/24 hr divided into four doses, not to exceed 25 mg/min I.V. or per I.M. site.

➤ *To treat sleep disorders*

## **CAPSULES, CHEWABLE TABLETS, ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS**

**Adults and adolescents.** 50 mg 20 to 30 min before bedtime.

➤ *To provide antitussive effects*

## **ELIXIR**

**Adults and adolescents.** 25 mg every 4 hr. *Maximum:* 150 mg/24 hr.

➤ *To treat symptoms of Parkinson's disease and drug-induced extrapyramidal reactions in elderly patients who can't tolerate more potent antidyskinetic drugs*

## **CAPSULES, CHEWABLE TABLETS, ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS**

**Adults.** 25 mg three or four times daily, increased gradually to 50 mg three or four times daily, as needed. *Maximum:* 300 mg daily.

## **I.V. OR I.M. INJECTION**

**Adults and adolescents.** 10 to 50 mg, not to exceed 25 mg/min I.V. or per I.M. site, as needed. *Maximum:* 100 mg/dose, 400 mg daily.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.	15-60 min	1-3 hr	6-8 hr
I.V.	Immediate	1-3 hr	6-8 hr
I.M.	30 min	1-3 hr	6-8 hr

## Mechanism of Action

Binds to central and peripheral H<sub>1</sub> receptors, competing with histamine for these sites and preventing it from reaching its site of action. By blocking histamine, diphenhydramine produces antihistamine effects, inhibiting GI, respiratory, and vascular smooth-muscle contraction; decreasing capillary permeability, which reduces flares, itching, and wheals; and decreasing lacrimal and salivary gland secretions.

Diphenhydramine produces antidyskinetic effects, possibly by inhibiting acetylcholine in the CNS. It also produces antitussive effects by directly suppressing the cough center in the medulla oblongata in the brain. Diphenhydramine's antiemetic and antivertigo effects may be related to its ability to bind to CNS muscarinic receptors and depress vestibular stimulation and labyrinthine function. Its sedative effects are related to its CNS depressant action.

## Contraindications

Breastfeeding; hypersensitivity to diphenhydramine, similar antihistamines, or their components; use in newborns or premature infants

## Interactions

### DRUGS

*barbiturates, other CNS depressants:* Possibly increased CNS depression

*MAO inhibitors:* Increased anticholinergic and CNS depressant effects of diphenhydramine

## **ACTIVITIES**

*alcohol use:* Possibly increased CNS depression

## **Adverse Reactions**

**CNS:** Confusion, dizziness, drowsiness

**CV:** **Arrhythmias**, palpitations, tachycardia

**EENT:** Blurred vision, diplopia

**GI:** Epigastric distress, nausea

**HEME:** **Agranulocytosis, hemolytic anemia, thrombocytopenia**

**RESP:** Thickened bronchial secretions

**SKIN:** Photosensitivity

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LACTATION**

- Drug is present in breast milk.

- Drug as an antihistamine poses a higher risk of adverse reactions in breastfed infants.
- Drug is contraindicated in breastfeeding women.

## Nursing Considerations

- Expect to give parenteral form of diphenhydramine only when oral ingestion isn't possible.
- Keep elixir container tightly closed. Protect elixir and parenteral forms from light.
- Expect to discontinue drug at least 72 hours before skin tests for allergies because drug may inhibit cutaneous histamine response, thus producing false-negative results.

## PATIENT TEACHING

- Instruct patient to take diphenhydramine at least 30 minutes before exposure to situations that may cause motion sickness.
- Advise her to take drug with food to minimize GI distress.
- Urge patient to avoid alcohol while taking diphenhydramine.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct her to use sunscreen to prevent photosensitivity reactions.
- Advise patient to avoid taking other OTC drugs that contain diphenhydramine to prevent additive effects.

**dipyrindamole**

**Persantine**

# Class and Category

*Pharmacologic class:* Pyrimidine analogue

*Therapeutic class:* Antiplatelet

## Indications and Dosages

- *As adjunct to coumarin anticoagulants to prevent postoperative thromboembolic complications of cardiac valve replacement*

### **TABLETS**

**Adults.** 75 to 100 mg four times daily with warfarin.

- *To aid diagnosis during thallium perfusion imaging of myocardium*

### **I.V. INFUSION**

**Adults.** 0.57 mg/kg in 50 ml of D<sub>5</sub>W infused over 4 min.

*Maximum:* 60 mg.

Route	Onset	Peak	Duration
I.V.	Unknown	Unknown	8.7 min*
P.O.	Unknown	75 min	Unknown

\* After start of infusion, for increased velocity of coronary artery blood flow.

## Mechanism of Action

May increase the intraplatelet level of adenosine, which causes coronary vasodilation and inhibits platelet aggregation. Dipyridamole also may increase the intraplatelet level of cyclic adenosine monophosphate (cAMP) and may inhibit formation of the potent platelet

activator stimulant thromboxane A<sub>2</sub>, which decreases platelet activation. Vasodilation and increased blood flow occur preferentially in nondiseased coronary vessels, which results in redistribution of blood away from significantly diseased vessels. These changes in perfusion are observed during thallium imaging studies.

## Contraindications

Hypersensitivity to dipyridamole or its components

## Interactions

### DRUGS

*adenosinergic agents such as adenosine, regadenoson:*

Potentiated cardiovascular effects of adenosine

*cholinesterase inhibitors:* Decreased anticholinesterase effect, possibly aggravating myasthenia gravis

*heparin, NSAIDs, thrombolytics:* Possibly increased risk of bleeding

*theophylline:* Reversal of coronary vasodilation caused by dipyridamole, possibly false-negative thallium imaging result

## Adverse Reactions

**CNS:** Dizziness, headache

**CV:** Angina, **arrhythmias, ECG changes (specifically ST-segment and T-wave changes)**

**GI:** Abdominal pain, diarrhea, nausea, vomiting

**RESP:** Dyspnea

**SKIN:** Flushing, pruritus, rash

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Be aware that if patients taking oral dipyridamole are scheduled to undergo stress testing using intravenous dipyridamole or other adenosinergic agents, the oral dosage of dipyridamole should be withheld for 48 hours before the test because of increased risk for cardiovascular adverse reactions and possibly impaired sensitivity of the test.
- Protect I.V. form of dipyridamole from direct light and freezing.
- Monitor blood pressure, pulse rate and rhythm, and breath sounds every 10 to 15 minutes during I.V. infusion.
- Keep parenteral aminophylline available to relieve adverse reactions to dipyridamole infusion.
- Expect adverse reactions to be minimal and transient at therapeutic doses. They typically resolve with long-term use.

## PATIENT TEACHING

- Urge patient to take dipyridamole at least 1 hour before or 2 hours after meals for faster absorption. If she experiences GI distress, advise her to take drug with meals or milk.
- Advise patient to take drug at evenly spaced intervals.

- Inform patient that drug commonly is taken with warfarin. Tell patient that aspirin should not be administered concomitantly with warfarin.
- Urge her to keep appointments for coagulation tests.
- Instruct patient to seek immediate emergency treatment if chest pain occurs.
- Caution patient to consult prescriber before taking over-the-counter NSAIDs because of the possible increased risk of bleeding.
- Advise patient to notify all healthcare providers about dipyridamole use.

## diroximel fumarate

**Vumerity**

### Class and Category

*Pharmacologic class:* Nuclear factor-like 2 (Nrf2) activator

*Therapeutic class:* Immunomodulatory agent

### Indications and Dosages

- *To treat relapsing forms of multiple sclerosis (MS), to include active secondary progressive disease, clinically isolated syndrome, and relapsing-remitting disease*

### E.R. CAPSULES

**Adults.** *Initial:* 231 mg twice daily followed by dosage increase to 462 mg twice daily after 7 days. *Maintenance:* 462 mg twice daily.

**DOSAGE ADJUSTMENT** For patient who cannot tolerate maintenance dosage, dosage reduced temporarily to 231 mg twice daily. Within 4 wk, dosage resumed at 462 mg twice daily.

## Mechanism of Action

Possibly activates the nuclear factor (erythroid-derived 2)-like 2 (Nrf2) pathway, which is involved in the cellular response to oxidative stress thought to be a factor in multiple sclerosis.

## Contraindications

Concurrent use of dimethyl fumarate, hypersensitivity to diroximel fumarate, dimethyl fumarate, or any of their components

## Interactions

### DRUGS

*dimethyl fumarate*: Potentiated effect increasing risk of serious adverse reactions

### ACTIVITIES

*alcohol use*: Possibly may reduce the plasma concentrations of monomethyl fumarate (MMF), the active metabolite of diroximel fumarate

## Adverse Reactions

**GI:** Abdominal pain, diarrhea, dyspepsia, elevated liver enzymes, nausea, vomiting

**GU:** Albumin present in urine

**HEME:** Lymphopenia

**SKIN:** Erythema, flushing, pruritus, rash

**Other:** Anaphylaxis, angioedema, progressive multifocal leukoencephalopathy

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Expect to obtain laboratory test results for alkaline phosphatase; complete blood cell count (CBC), including lymphocyte count; serum aminotransferase; and total bilirubin levels prior to starting diroximel.
- Obtain an MRI at baseline and as clinically indicated to assess for signs of PML.
- Be aware that diroximel is not recommended for patients with moderate or severe renal impairment.
- Administer nonenteric coated aspirin up to a dose of 325 mg 30 minutes before administering diroximel, as ordered, to reduce the incidence or severity of flushing.
- Know that a high-fat (more than 30 grams) or a high-calorie (more than 700 calories) meal or snack will interfere with the absorption of diroximel.

**WARNING** Monitor patient closely for hypersensitivity reactions such as anaphylaxis and angioedema, which have occurred as early as after the first dose and throughout the duration of drug therapy.

- Obtain a CBC, including lymphocyte count, 6 months after drug therapy has begun and then every 6 to 12 months thereafter, as indicated and ordered. Also expect to obtain laboratory results for alkaline phosphatase, serum aminotransferase, and total bilirubin levels during drug therapy, as indicated and ordered.

**WARNING** Monitor patient for signs and symptoms of progressive multifocal leukoencephalopathy (PML) such as changes in memory, orientation, or thinking leading to confusion and personality changes, as well as clumsiness of limbs, progressive weakness on one side of the body, and visual disturbances. Although no reports of PML have occurred with cladribine for treating relapsing forms of MS, it is a possibility. At first sign of PML, notify prescriber, expect cladribine to be withheld, and ensure that appropriate diagnostic evaluation is done. Know that MRI findings may reveal PML before clinical signs or symptoms are apparent.

- Monitor patient for signs and symptoms of infections, which could become serious because drug decreases the lymphocyte count. Know that drug therapy may have to be interrupted if lymphocyte counts less than  $0.5 \times 10^9/L$  persist for more than 6 months or if serious infections occur (until infections are resolved).
- Know that although liver injury has not been reported with diroximel therapy, it is a high possibility because drug contains the same active metabolite as dimethyl fumarate, which has caused liver injury. Expect to monitor patient's alkaline phosphatase, serum aminotransferase, and total bilirubin throughout drug therapy. If significant liver injury is suspected, drug will have to be discontinued.

## **PATIENT TEACHING**

- Instruct patient to take a nonenteric coated aspirin, up to a dose of 325 mg, 30 minutes before administering diroximel, if ordered to reduce the incidence or severity of flushing caused by the drug. Taking drug with food may also help reduce the incidence of flushing.
- Tell patient to swallow capsule whole and not to chew, crush, or sprinkle capsule contents on food.
- Remind patient to avoid taking drug with a high-fat, high-calorie meal/snack; meal or snack should contain no more than 700 calories and no more than 30 grams of fat.
- Advise patient to avoid coadministration of drug with alcohol.

**WARNING** Advise patient to stop taking drug and seek emergency medical care if signs and symptoms of an allergic reaction occur.

- Instruct patient to report any unexplained or unusual signs and symptoms to prescriber. Also instruct patient to report persistent and/or severe GI reactions or flushing.
- Stress importance of being compliant with scheduled laboratory tests.

## disulfiram

### Antabuse

## Class and Category

*Pharmacologic class:* Aldehyde dehydrogenase inhibitor

*Therapeutic class:* Alcohol deterrent

## Indications and Dosages

- *As adjunct to maintain sobriety in treatment of chronic alcoholism*

## TABLETS

**Adults.** *Initial:* Up to 500 mg daily for 1 to 2 wk.

*Maintenance:* 125 to 500 mg daily. *Maximum:* 500 mg daily.

Route	Onset	Peak	Duration
P.O.	1-2 hr	Unknown	Up to 14 days

## Mechanism of Action

Interferes with the enzyme responsible for hepatic oxidation of acetaldehyde to acetate, which occurs during alcohol catabolism. Ingestion of even a small amount of alcohol after taking disulfiram raises the blood acetaldehyde level to 5 to 10 times normal. Disulfiram doesn't alter the rate of alcohol elimination. Its major metabolite, diethyldithiocarbamate, inhibits norepinephrine synthesis and may be responsible for the drug's hypotensive effect.

## Contraindications

Alcohol intoxication; coronary artery occlusion; hypersensitivity to disulfiram, other thiuram derivatives used in pesticides and rubber vulcanization, or their components; psychosis; recent use of alcohol, alcohol-containing preparations, metronidazole, or paraldehyde; severe myocardial disease

## Interactions

## **DRUGS**

*alcohol-containing preparations, amitriptylline:* Increased sensitivity to alcohol in product, resulting in disulfiram-alcohol reaction

*barbiturates:* Increased blood barbiturate concentration possibly resulting in barbiturate toxicity

*isoniazid:* Increased risk of behavioral changes, incoordination, marked changes in mental status, psychotic reactions, or unsteady gait

*metronidazole:* Risk of CNS toxicity, resulting in confusion and psychosis

*oral anticoagulants:* Possibly increased anticoagulant effects

*phenytoin:* Possibly increased blood phenytoin level and risk of phenytoin toxicity

## **ACTIVITIES**

*alcohol use:* Increased sensitivity to alcohol, resulting in disulfiram-alcohol reaction

## **FOOD**

*caffeine (ingested in large amounts):* Possibly exaggerated or prolonged caffeine effects

## **Adverse Reactions**

**CNS:** Drowsiness, headache, peripheral neuropathy, psychotic reaction, tiredness

**EENT:** Blurred vision, garlic or metallic taste, optic atrophy, optic neuritis

**GU:** Impotence

**SKIN:** Rash

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug maybe present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Keep in mind that disulfiram is given only to patients who are highly motivated to stop drinking and who are receiving psychotherapy or substance abuse counseling.
- Know that the alcohol content of patient's other drugs should be checked before starting therapy.

**WARNING** Never give drug to patient without her knowledge or if she is intoxicated.

- Crush tablet and mix with fluids before administration, if needed.
- Don't give drug within 14 days of patient's ingestion of alcohol-containing substance.
- Expect alcohol ingestion during disulfiram therapy to produce a severe reaction that lasts from 30 minutes to several hours. Symptoms may include angina, anxiety, blurred vision, confusion, diaphoresis, dyspnea, heart failure, hypotension, nausea, palpitations, sinus tachycardia, syncope, thirst, throbbing headache, throbbing in neck, vertigo, vomiting, and weakness. A deep sleep usually follows.

**WARNING** Be aware that the ingestion of three or more alcoholic beverages with a disulfiram dose greater than 500 mg daily may cause respiratory depression, arrhythmias, and cardiac arrest.

- Know that if patient takes phenytoin, monitor blood phenytoin level before and during disulfiram therapy, and adjust dosage of either drug as prescribed. Interactions may not occur if disulfiram therapy starts before phenytoin therapy. A subtherapeutic phenytoin level may result if disulfiram therapy stops.
- Be aware that if patient takes an oral anticoagulant, monitor PT before and during disulfiram therapy, and adjust anticoagulant dosage as prescribed. Drug interactions may not occur if disulfiram therapy starts before warfarin therapy. If disulfiram therapy stops, be prepared to adjust warfarin dosage to avoid loss of hypoprothrombinemic effects.
- Expect some adverse reactions, such as drowsiness, headache, and impotence, to subside over time or with a brief dosage reduction.
- Know that because one-fifth of a disulfiram dose may stay in the body for 1 week or longer, alcohol ingestion may continue to produce unpleasant symptoms for up to 2 weeks after therapy stops.
- Expect therapy to last months to years, depending on patient's ability to abstain from alcohol.

## **PATIENT TEACHING**

- Teach patient's household and family members about precautions needed and risks associated with disulfiram therapy.
- Explain that drug doesn't cure alcoholism but does help deter alcohol consumption.
- Advise her to take drug in the evening if she reports daytime drowsiness.
- Warn patient to avoid alcohol-containing substances, such as cough syrup, sauces, and vinegar during therapy because a disulfiram-alcohol reaction may occur after ingesting as little as 15 ml of 100-proof alcohol. Urge her to avoid alcohol-containing liniments and lotions as well.
- Teach patient what to expect if disulfiram-alcohol reaction occurs. Inform her that a deep sleep usually follows the reaction.

- Advise patient that a reaction can occur up to 14 days after therapy stops and that a severe reaction may cause arrhythmias, cardiac arrest, and respiratory depression.
- Instruct patient to carry medical identification that indicates drug, describes possible reactions, and lists someone to notify in case of emergency.

## dobutamine hydrochloride

### Class and Category

*Pharmacologic class:* Sympathomimetic

*Therapeutic class:* Inotropic

### Indications and Dosages

- *To treat low cardiac output and heart failure short term*

#### I.V. INFUSION

**Adults and children. Initial:** 0.5 to 1.0 mcg/kg/min as continuous infusion adjusted every couple of minutes according to hemodynamic response. *Usual maintenance:* 2 to 20 mcg/kg/min. *Maximum:* 40 mcg/kg/min.

Route	Onset	Peak	Duration
I.V.	1-2 min	Unknown	Under 5 min

### Mechanism of Action

Mainly stimulates beta<sub>1</sub>-adrenergic receptors, and mildly stimulates beta<sub>2</sub>- and alpha<sub>1</sub>-adrenergic receptors. Beta<sub>1</sub>-receptor stimulation produces a positive inotropic effect on the myocardium, increasing cardiac output by boosting myocardial contractility and stroke volume. Increased myocardial contractility raises coronary blood flow and myocardial oxygen consumption. Systolic blood pressure typically rises as a result of increased stroke volume. Other hemodynamic effects include decreased systemic vascular resistance, which reduces afterload, and decreased ventricular filling pressure, which reduces preload.

## **Incompatibilities**

Don't combine dobutamine with cefamandole, cefazolin, hydrocortisone sodium succinate, cephalothin, penicillin, sodium ethacrylate, and sodium heparin because of incompatibility. Don't mix dobutamine with alkaline solutions, such as sodium bicarbonate, because of possible physical incompatibility. Don't use diluents that contain sodium bisulfite or ethanol.

## **Contraindications**

Hypersensitivity to dobutamine or its components, idiopathic hypertrophic subaortic stenosis

## **Interactions**

### **DRUGS**

*catechol-O-methyltransferase (COMT) inhibitors such as entacapone*: Possibly increased incidence of arrhythmias, changes in blood pressure, and heart rate

*nitroprusside*: Increased cardiac output and lowered pulmonary wedge pressure

## Adverse Reactions

**CNS:** Fever, headache, nervousness, restlessness

**CV:** Angina, **bradycardia**, hypertension, **hypotension**, nonspecific chest pain, palpitations, **PVCs**, **stress cardiomyopathy** (with cardiac stress testing), tachycardia

**GI:** Nausea, vomiting

**RESP:** Dyspnea, shortness of breath

**SKIN:** Extravasation with tissue necrosis and sloughing, rash

**Other:** **Hypokalemia**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Due to critical nature of situation, breastfeeding would not be done during drug therapy.

## Nursing Considerations

- Avoid giving dobutamine to patients with uncorrected hypovolemia. Expect prescriber to order whole blood or plasma volume expanders to correct hypovolemia. Also avoid giving dobutamine to patients with acute MI because it can intensify or extend myocardial ischemia.
- Use drug cautiously in patients allergic to sulfites because drug may cause anaphylactic-like signs and symptoms; commercially available dobutamine injections contain sodium bisulfite. Also use drug cautiously in patients with atrial fibrillation because drug increases AV conduction. Keep in mind that patient should be adequately digitalized before administration.
- Dilute concentrate with at least 50 ml compatible I.V. solution. A common dilution is 500 mg (40 ml from 250-ml bag) in 210 ml D<sub>5</sub>W or normal saline solution to yield 2,000 mcg/ml. Or dilute 1,000 mg (80 ml from 250-ml bag) in 170 ml D<sub>5</sub>W or normal saline solution to yield 4,000 mcg/ml. Adjust maximum concentration according to patient's fluid requirements as prescribed. Don't exceed 5,000 mcg/ml. Discard solution after 24 hours.
- Inspect parenteral solution for particles and discoloration before administering it.
- Give I.V. drug using an infusion pump.
- Monitor blood pressure continuously during therapy, preferably by continuous intra-arterial monitoring; systolic increase of 10 to 20 mm Hg may indicate dobutamine-induced increase in cardiac output.
- Expect to reduce dosage or discontinue drug if hypotension develops.
- Monitor heart rate and rhythm via ECG recordings continuously for PVCs, which may result from drug's stimulatory effect on heart's conduction system, and sinus tachycardia, which results from positive chronotropic effect of beta stimulation and may increase heart rate by 5 to 15 beats/minute.
- Monitor hemodynamic parameters, such as cardiac output, central venous pressure, and pulmonary artery wedge pressure, as indicated, to assess drug's effectiveness.

**WARNING** Monitor serum potassium level to check for hypokalemia, a rare result of beta<sub>2</sub> stimulation that causes electrolyte imbalance.

- Monitor urine output hourly, as appropriate, to check for improved renal blood flow.

- Know that dobutamine isn't indicated for long-term treatment of heart failure because it may not be effective and may increase the risk of hospitalization and death.

## **PATIENT TEACHING**

- Explain the need for frequent hemodynamic monitoring.

**docusate calcium**

**(dioctyl calcium sulfosuccinate)**

**Doxidan (CAN), Surfak**

**docusate potassium**

**(dioctyl potassium sulfosuccinate)**

**Kasof**

**docusate sodium**

**(dioctyl sodium sulfosuccinate)**

**Colace, Colax, Correctol, Dialose,  
Diocto, DOK, D.O.S., Silace**

## **Class and Category**

*Pharmacologic class:* Surfactant

*Therapeutic class:* Laxative, stool softener

## Indications and Dosages

➤ *To treat constipation*

### **CAPSULES, LIQUID, SYRUP, TABLETS (ALL SALTS)**

**Adults and adolescents.** 50 to 400 mg in 1 to 4 divided doses.

**Children ages 6 to 12 using docusate sodium.** 40 to 150 mg in 1 to 4 divided doses.

**Children ages 3 to 6 using docusate sodium.** 20 to 60 mg in 1 to 4 divided doses.

**Children under age 3 using docusate sodium.** 10 to 40 mg in 1 to 4 divided doses.

### **RECTAL ENEMA (DOCUSATE SODIUM)**

**Adults.** 200 to 283 mg once or twice. Alternatively, 50 to 100 mg of docusate sodium liquid added to a retention or flushing enema once daily, as needed.

**Children age 3 and over.** 200 to 283 mg once daily, as needed. Alternatively, 50 to 100 mg of docusate sodium liquid added to a retention or flushing enema once daily, as needed.

Route	Onset	Peak	Duration
P.O.	24–72 hr	Unknown	Unknown
Rectal	within 24 hr	Unknown	Unknown

## Mechanism of Action

Acts as a surfactant that softens stool by decreasing surface tension between oil and water in feces. This action lets more fluid penetrate stool, forming a softer fecal mass.

## **Contraindications**

Concomitant use with mineral oil; fecal impaction; hypersensitivity to docusate salts or their components; intestinal obstruction; nausea, vomiting, or other symptoms of appendicitis; undiagnosed abdominal pain, use for more than 7 days when self-medicating

## **Interactions**

### **DRUGS**

*mineral oil*: Increased mineral oil absorption, increased risk of toxicity

## **Adverse Reactions**

**CNS**: Dizziness, syncope

**CV**: Palpitations

**GI**: Abdominal cramps and distention, diarrhea, nausea, perianal irritation, vomiting

**MS**: Muscle weakness

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Expect excessive or long-term use of docusate to cause dependence on laxatives for bowel movements, electrolyte imbalances, osteomalacia, steatorrhea, and vitamin and mineral deficiencies.

- Assess for laxative abuse syndrome, especially in women with anorexia nervosa, depression, or personality disorders.

## PATIENT TEACHING

- Tell patient not to use docusate when she has abdominal pain, nausea, or vomiting.
- Advise patient to take docusate with a full glass of milk or water.
- Encourage patient to increase fiber intake, exercise regularly, and drink 6 to 8 glasses (240 ml/glass) of water daily to help prevent constipation.
- Instruct patient to notify prescriber about rectal bleeding; symptoms of electrolyte imbalances, such as dizziness, light-headedness, muscle cramping, and weakness; and unrelieved constipation.

**dofetilide**

**Tikosyn**

# Class and Category

*Pharmacologic class:* Class III antiarrhythmic

*Therapeutic class:* Antiarrhythmic

## Indications and Dosages

- *To convert symptomatic atrial fibrillation or flutter to normal sinus rhythm or to maintain normal sinus rhythm in patients converted from symptomatic atrial fibrillation or flutter*

### CAPSULES

**Adults.** Highly individualized based on creatinine clearance and QTc (QT interval used if heart rate is below 60 beats per min). *Usual:* 500 mcg twice daily for patients with creatinine clearance above 60 ml/min. *Maximum:* 500 mcg twice daily.

***DOSAGE ADJUSTMENT*** For patient with renal impairment, initial dose reduced to 250 mcg twice daily if creatinine clearance is 40 to 60 ml/min and to 125 mcg twice daily if clearance is 20 to 39 ml/min, as prescribed. If, 2 to 3 hr after initial dose, QTc interval has increased by at least 15% or is more than 500 milliseconds (msec) (550 msec in patients with ventricular conduction abnormalities), dosage decreased by 50%, as prescribed. However, for patients receiving lowest initial dose of 125 mcg twice daily, dosage reduced to 125 mcg daily, as prescribed. If at any time after second dose, QTc interval increases to more than 500 msec (550 msec in patients with ventricular conduction abnormalities), expect to discontinue drug, as prescribed.

Route	Onset	Peak	Duration
P.O.	Unknown	2 hr	4 hr

## Mechanism of Action

Selectively blocks potassium channels in myocardial cell membranes involved in cardiac repolarization. By blocking potassium channels, dofetilide prolongs action potential duration, effective refractory period, and ventricular refractoriness (widens QT interval). These actions terminate or prevent reentrant tachyarrhythmias, such as atrial fibrillation, atrial flutter, and ventricular tachycardia.

## Contraindications

Acquired or congenital QT prolongation syndrome; concurrent therapy with cimetidine, dolutegravir, hydrochlorothiazide, ketoconazole, megestrol, prochlorperazine, trimethoprim, or verapamil; hypersensitivity to dofetilide or its components; severe renal impairment (creatinine clearance less than 20 ml/min)

## Interactions

### DRUGS

*amiloride, cimetidine, cotrimoxazole, ketoconazole, megestrol, metformin, sulfamethoxazole-trimethoprim, triamterene, trimethoprim:* Possibly increased blood dofetilide level

*azole antifungals, cannabinoids, diltiazem, nefazodone, norfloxacin, protease inhibitors, quinine, selective serotonin reuptake inhibitors, zafirlukast:* Possibly increased blood dofetilide level and risk of dofetilide toxicity

*bepidil, cisapride, macrolide antibiotics, phenothiazines, selected fluoroquinolones, tricyclic antidepressants:*

Possibly prolonged QT interval  
*class I and III antiarrhythmics, especially amiodarone:*  
Possibly prolonged QT interval and increased risk of  
dofetilide-induced proarrhythmias  
*diuretics (potassium-depleting):* Increased risk of torsades  
de pointes in patients with hypokalemia or  
hypomagnesemia  
*hydrochlorothiazide, verapamil:* Possibly increased blood  
dofetilide level and increased risk of torsades de pointes

## **FOODS**

*grapefruit juice:* Increased dofetilide level

## **Adverse Reactions**

**CNS:** Cerebral ischemia, CVA, dizziness, facial or flaccid  
paralysis, headache, insomnia, paresthesia, slurred speech,  
syncope

**CV:** AV block, bradycardia, cardiac arrest, chest pain,  
edema, MI, tachycardia, ventricular arrhythmias  
(including torsades de pointes and ventricular  
tachycardia)

**GI:** Abdominal pain, diarrhea, hepatic dysfunction,  
jaundice, nausea

**MS:** Back pain, muscle weakness

**RESP:** Cough, dyspnea, respiratory tract infection

**SKIN:** Rash

**Other:** Angioedema, flu-like symptoms, weight gain

## **Childbearing Considerations**

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding during drug therapy.

## Nursing Considerations

**WARNING** Be aware that dofetilide shouldn't be started if patient has previously received amiodarone until blood amiodarone level is less than 0.3 mcg/ml or until amiodarone has been withdrawn for at least 3 months.

- Evaluate and document QTc interval before and during dofetilide therapy.
- Place patient on continuous ECG monitoring for at least 3 days, as ordered, during dofetilide therapy.

**WARNING** Know that if patient does not convert to normal sinus rhythm within 24 hours of starting dofetilide, expect possible synchronized electrical cardioversion.

- Be prepared to reevaluate renal function and QTc interval every 3 months, as ordered, during dofetilide therapy.
- Monitor continuous ECG for at least 30 hours, as ordered when switching to dofetilide from class I or class III antiarrhythmics, or after withdrawing antiarrhythmic treatment.
- Be aware that if patient requires a drug that may interact with dofetilide, expect to discontinue dofetilide, as prescribed, for 2 or more days before starting the other drug.

**WARNING** Monitor laboratory test results for hypokalemia or hypomagnesemia, especially in patients taking diuretics, because of the increased risk of dofetilide-induced torsades de pointes.

- Monitor women often for adverse reactions, including prolonged QTc interval and torsades de pointes; they have 12% to 18% lower renal clearance of drug than men and therefore a greater risk of adverse reactions.

## **PATIENT TEACHING**

- Advise patient to swallow dofetilide capsules with water.
- Instruct patient to avoid drinking grapefruit juice while taking this drug.
- Inform patient that she may be hospitalized for at least 3 days if dofetilide dosage is increased.
- Teach patient to measure blood pressure and pulse rate during dofetilide therapy.
- Urge patient to report chest discomfort, fluttering, or palpitations immediately.
- Tell patient to notify prescriber immediately if she experiences loss of appetite, severe diarrhea, unusual sweating, or vomiting, or if she develops excessive thirst that may occur as a result of certain drug interactions that cause an electrolyte imbalance.
- Advise patient to consult prescriber before using any OTC drugs, nutritional supplements, or herbal products.
- Instruct patient to keep follow-up appointments to monitor heart rhythm.

**dolasetron mesylate**

**Anzemet**

# Class and Category

*Pharmacologic class:* Selective serotonin receptor antagonist

*Therapeutic class:* Antiemetic

## Indications and Dosages

- *To prevent nausea and vomiting due to chemotherapy*

### ORAL SOLUTION, TABLETS

**Adults and children over age 16.** 100 mg within 1 hr before chemotherapy.

**Children ages 2 to 16.** 1.8 mg/kg within 1 hr before chemotherapy. *Maximum:* 100 mg/dose.

- *To prevent postoperative nausea and vomiting*

### I.V. INFUSION, I.V. INJECTION

**Adults and children over age 16.** 12.5 mg 15 min before end of anesthesia. I.V. injection given rapidly, at 100 mg per 30 seconds, or I.V. infusion diluted to 50 ml and infused up to 15 min.

**Children ages 2 to 16.** 0.35 mg/kg 15 min before end of anesthesia. *Maximum:* 12.5 mg/dose. I.V. injection given rapidly, at 100 mg per 30 seconds, or I.V. infusion diluted to 50 ml and infused up to 15 min.

- *To treat postoperative nausea and vomiting*

### I.V. INFUSION, I.V. INJECTION

**Adults and children over age 16.** 12.5 mg as single dose as soon as symptoms develop. I.V. injection given rapidly, at 100 mg per 30 seconds, or I.V. infusion diluted to 50 ml and infused up to 15 min.

**Children ages 2 to 16.** 0.35 mg/kg as single dose as soon as symptoms develop. I.V. injection given rapidly, at 100 mg per 30 seconds, or I.V. infusion diluted to 50 ml and infused up to 15 min. *Maximum:* 12.5 mg/dose.

## Mechanism of Action

With its active metabolite hydrodolasetron, prevents activation of serotonin 5-HT<sub>3</sub> receptors located centrally in chemoreceptor trigger zone and peripherally on vagal nerve terminals thereby decreasing the vomiting reflex.

## Contraindications

Congenital long-QT syndrome, hypersensitivity to dolasetron or its components, intravenous administration to prevent nausea and vomiting associated with cancer chemotherapy, use with apomorphine

## Interactions

### DRUGS

*apomorphine:* Increased risk of loss of consciousness and profound hypotension

*atenolol:* Possibly decreased dolasetron clearance

*cimetidine:* Possibly increased blood dolasetron level

*drugs that prolong ECG intervals or cause hypokalemia or*

*hypomagnesemia:* Increased risk of serious arrhythmia

*fentanyl, I.V. methylene blue, lithium, mirtazapine, MAO*

*inhibitors, selective serotonin reuptake inhibitors,*

*serotonin and norepinephrine reuptake inhibitors:*

Increased risk of serotonin syndrome

*rifampin:* Possibly decreased blood dolasetron level

# Adverse Reactions

**CNS:** Headache, **serotonin syndrome**

**CV:** **Cardiac arrest**; hypertension; **hypotension**; **MI**; **prolongation of QT, PR, and QRS intervals in ECG**; **torsades de pointes**; **ventricular fibrillation and tachycardia**; **wide-complex tachycardia**

**GI:** Diarrhea

**SKIN:** Rash

**Other:** injection-site pain

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Correct hypokalemia and hypomagnesemia, if present and as ordered, prior to administering dolasetron intravenously as serious arrhythmias may result.
- Expect to give up to 100 mg of dolasetron I.V. in 30 seconds or to dilute it in normal saline solution, D<sub>5</sub>W, dextrose 5% in half-normal (0.45) saline solution, or lactated Ringer's solution and infuse for up to 15 minutes, as prescribed.

- Flush I.V. line with compatible solution before and after drug administration.
- Expect to prepare an oral solution of dolasetron for patients unable to swallow tablets by diluting injection solution with apple or apple-grape juice.

**WARNING** Assess patient for ECG changes, including prolonged PR, QTc, and QT intervals and widened QRS complex, especially in patients with bradycardia or underlying heart disease, congestive heart failure, the elderly, and patients with renal impairment during intravenous dolasetron therapy.

**WARNING** Monitor patient for serotonin syndrome, which is characterized by agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. In its most severe form, serotonin syndrome can resemble neuroleptic malignant syndrome, which includes a high fever, muscle rigidity, autonomic instability with possible fluctuations in vital signs, mental status changes, and mental status changes.

## **PATIENT TEACHING**

- Explain that oral solution can be prepared by diluting injection form of drug with apple or apple-grape juice for children or patients who have trouble swallowing.
- Inform patient that oral solution may be refrigerated for up to 48 hours but should be discarded after 2 hours at room temperature.
- Advise patient to notify prescriber immediately if he experiences dizziness, palpitations, or an abnormally slow or irregular pulse after receiving dolasetron intravenously.

**WARNING** Instruct patient to seek immediate medical attention if he experiences erratic changes in his blood pressure, heart beat, or temperature; changes in his

mental status; adverse gastrointestinal symptoms; or neuromuscular symptoms.

## dolutegravir

**Tivicay**

### Class and Category

*Pharmacologic class:* Integrase strand transfer inhibitor (INSTI)

*Therapeutic class:* Antiretroviral

### Indications and Dosages

- *As adjunct to treat human immunodeficiency virus type 1 (HIV-1) in combination with other antiretroviral agents; as adjunct with rilpivirine as a complete regimen for the treatment of HIV-1 infection in adults to replace the current antiretroviral regimen in those who are virologically suppressed (HIV- RNA less than 50 copies/ml) on a stable antiretroviral regimen for at least 6 months with no history of treatment failure or known substitutions associated with resistance to either antiretroviral agent*

### **TABLETS**

**Adults who are treatment-naïve, treatment-experienced INSTI-naïve, or virologically suppressed**

**and switching to dolutegravir plus rilpivirine. 50 mg once daily.**

**Adults who are treatment-naïve or treatment-experienced INSTI-naïve who are currently receiving certain CYP3A or UGT1A inducers such as carbamazepine, efavirenz, fosamprenavir/ritonavir, rifampin, or tipranavir/ritonavir; adults who are INSTI-experienced who have certain INSTI-associated resistance substitutions or clinically suspected INSTI resistance. 50 mg twice daily.**

**Children who are treatment-naïve or treatment-experienced INSTI-naïve and weigh at least 40 kg (88 lb) or more. 50 mg once daily.**

**Children who are treatment-naïve or treatment-experienced INSTI-naïve and weigh at least 30 kg (66 lb) but less than 40 kg (88 lb). 35 mg once daily.**

***DOSAGE ADJUSTMENT*** For children: Concurrent therapy with certain CYP3A or UGT1A inducers such as carbamazepine, efavirenz, fosamprenavir/ritonavir, rifampin, or tipranavir/ritonavir, dosage frequency increased to twice daily regardless of weight.

## **Mechanism of Action**

Inhibits HIV integrase by binding to the integrase active site and blocking the strand transfer step of retroviral DNA integration, which is needed for the HIV replication cycle.

## **Contraindications**

Concurrent therapy with dofetilide, hypersensitivity to dolutegravir or its components

# Interactions

## DRUGS

*buffered medications, calcium- or iron-containing products, carbamazepine, cation-containing antacids or laxatives, efavirenz, etravirine, fosamprenavir/ritonavir, nevirapine, oxcarbazepine, phenobarbital, phenytoin, rifampin, St. John's wort, sucralfate, tipranavir/ritonavir:* Decreased plasma dolutegravir levels leading to decreased effectiveness

*CYP3A or UGT1A inhibitors:* Increased plasma dolutegravir levels with possible increased adverse reactions

*dofetilide:* Possibly increased plasma dolutegravir levels leading to potential toxicity

*metformin:* Increased plasma metformin levels increasing risk of adverse reactions

## Adverse Reactions

**CNS:** Abnormal dreams, depression, dizziness, fatigue, fever, general malaise, headache, insomnia, **suicidal ideation**, vertigo

**CV:** Elevated cholesterol or triglycerides

**EENT:** Conjunctivitis, oral blisters or lesions

**ENDO:** Cushingoid appearance, fat redistribution, hyperglycemia

**GI:** Abdominal discomfort or pain, **acute liver failure**, diarrhea, elevated bilirubin or liver enzymes, flatulence, **hepatitis, hepatitis B reactivation, hepatotoxicity, liver injury**, nausea, vomiting

**GU:** Elevated creatinine level, renal impairment

**HEME:** Eosinophilia

**MS:** Arthralgia, elevated creatine kinase, joint or muscle aches, myalgia, myositis

**RESP:** **Difficulty breathing**

**SKIN:** Blisters, peeling of skin, pruritus, rash

**Other:** **Angioedema**, elevated lipase, immune reconstitution syndrome, weight gain

## **Childbearing Considerations**

### **PREGNANCY**

- Pregnancy exposure registry: 1-800-258-4263.
- Pregnancy testing should be done in women of childbearing age prior to initiation of drug therapy.
- Drug may cause fetal harm, especially if given at time of conception or during the first trimester, increasing risk of neural tube defects.
- Drug should be discontinued as soon as pregnancy is known unless there is no suitable alternative.

### **LACTATION**

- It is not known if drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

### **REPRODUCTION**

- Effective contraceptive measures should be in place prior to beginning drug therapy as well as throughout therapy.

# Nursing Considerations

- Expect to perform a pregnancy test in women of childbearing age before dolutegravir therapy is begun, because drug increases risk of neural tube defects in the fetus if administered at the time of conception and in early pregnancy.

**WARNING** Monitor patient closely for hypersensitivity reactions that may include a severe rash or a rash accompanied by angioedema, conjunctivitis, difficulty breathing, eosinophilia, facial edema, fatigue, fever, general malaise, hepatitis, joint or muscle aches, oral blisters or lesions, and skin blisters or peeling. Report any such signs and symptoms to prescriber immediately. Expect liver enzymes to be checked, as ordered. Provide supportive care as ordered and expect dolutegravir therapy to be discontinued if hypersensitivity is thought to be drug induced, because a life-threatening reaction may occur if therapy is continued.

- Monitor patients with hepatitis B or C for development or worsening of elevated transaminase levels.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including dolutegravir. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.
- Watch closely for suicidal tendencies, as dolutegravir may cause suicidal ideation.

## PATIENT TEACHING

- Tell women of childbearing age that a pregnancy test will be done before dolutegravir therapy is begun, because drug can be toxic to the fetus if taken at time of conception and early in pregnancy. Warn patient to use effective contraceptive measures while taking drug. If pregnancy occurs during dolutegravir therapy, tell patient to contact prescriber immediately. If confirmed, encourage patient to register with the Antiretroviral Pregnancy Registry at 1-800-258-4263. Expect patient to be switched to a different drug during the first trimester of pregnancy.
- Inform patient that dolutegravir will be prescribed along with other antiviral drugs.
- Instruct patient that if a dose is missed to take it as soon as he remembers and not to double the next dose to make up for the missed dose or take more of the drug than prescribed.
- Tell patient to store the tablets in the original package, keep the bottle tightly closed, and protect from moisture. Stress importance of not removing desiccant.

**WARNING** Review signs and symptoms of a hypersensitivity reaction with patient. Stress importance of reporting blistering or peeling of skin, difficulty breathing, facial swelling, feelings of fatigue, fever, joint or muscle aches, liver problems (dark urine, nausea, pale-colored stools, vomiting, or yellowing of skin or whites of eyes), rash, or any other unusual sign or symptoms immediately, as drug therapy may have to be discontinued to prevent a life-threatening reaction.

- Inform patient that dolutegravir therapy may cause changes in his body appearance because of fat redistribution. Prepare him for the possibility of developing breast enlargement, central obesity, dorsocervical fat enlargement (buffalo hump), facial wasting, and peripheral wasting.
- Instruct patient to report any persistent, severe, or unusual signs and symptoms. This is especially important for any signs or symptoms of infection that may occur soon after drug therapy is started.
- Warn family or caregiver to watch patient closely for evidence of suicidal behavior or thinking.
- Advise patient to alert prescriber of all medications taken, including over the counter drugs or herbal products such as St. John's wort.

- Tell patient that blood tests are usually done throughout drug therapy to monitor liver function, especially in patients with underlying liver disease.
- Alert mothers that breastfeeding is not recommended during dolutegravir therapy.

## donepezil hydrochloride

**Aricept, Aricept ODT**

### Class and Category

*Pharmacologic class:* Acetylcholinesterase inhibitor

*Therapeutic class:* Antidementia

### Indications and Dosages

➤ *To treat mild to moderate Alzheimer's disease*

#### **ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS**

**Adults.** *Initial:* 5 mg at bedtime. After 4 to 6 wk, dosage increased to 10 mg at bedtime, as indicated. *Maximum:* 10 mg daily.

➤ *To treat moderate to severe Alzheimer's disease*

#### **ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS**

**Adults.** *Initial:* 5 mg at bedtime. After 4 to 6 wk, dosage increased to 10 mg at bedtime, as indicated. Dosage may be further increased, as needed, after 3 months to 23 mg

daily at bedtime if using tablet form. *Maximum:* 10 mg daily for oral solution and orally disintegrating tablets, 23 mg daily for tablets.

## Mechanism of Action

Reversibly inhibits acetylcholinesterase and improves acetylcholine's concentration at cholinergic synapses. Raising acetylcholine level in the cerebral cortex may improve cognition. Donepezil becomes less effective as Alzheimer's disease progresses and number of intact cholinergic neurons declines.

## Contraindications

Hypersensitivity to donepezil, piperidine derivatives, or their components

## Interactions

### DRUGS

*anticholinergics:* Possibly interference with activity of these drugs

*cholinergic agonists, succinylcholine and similar*

*neuromuscular blockers:* Possibly synergistic effects of these drugs

## Adverse Reactions

**CNS:** Abnormal gait, agitation, aggression, anxiety, asthenia, confusion, depression, dizziness, dream disturbances, fatigue, fever, hallucinations, headache, hostility, insomnia, nervousness, **neuroleptic malignant syndrome**, **seizures**, somnolence, syncope, tremor

**CV:** **Abnormal ECG, AV block, bradycardia**, chest pain, edema, **heart failure**, hypertension, **hypotension**, **prolonged QT interval, torsades de pointes**

**EENT:** Pharyngitis

**ENDO:** Hyperglycemia

**GI:** Abdominal pain, anorexia, cholecystitis, constipation, diarrhea, dyspepsia, fecal incontinence, gastroenteritis, **hepatitis**, nausea, **pancreatitis**, vomiting

**GU:** Cystitis, glycosuria, hematuria, urinary frequency or incontinence, UTI

**HEME:** Anemia, **hemolytic hemorrhage**

**MS:** Arthralgia, back pain, elevated creatine kinase level, muscle cramps or spasms, **rhabdomyolysis**

**RESP:** Bronchitis, increased cough, pneumonia

**SKIN:** Ecchymosis, eczema, pruritus, rash, ulceration

**Other:** **Angioedema**, dehydration, elevated alkaline phosphatase or lactate dehydrogenase level, flu-like syndrome, **hyponatremia**, weight loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.

- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Use donepezil cautiously in patients with bladder obstruction because drug's weak peripheral cholinergic effect could obstruct outflow.
- Use drug cautiously in patients with asthma, COPD, or other pulmonary disorders because it has weak affinity for peripheral cholinesterase, which may increase bronchoconstriction and bronchial secretions.
- Know that if patient has cardiac disease, monitor heart rate and rhythm for bradycardia, which may result from increased vagal tone caused by drug's inhibition of peripheral cholinesterase. Reduced heart rate may be especially significant if patient has bradycardia, sick sinus syndrome, or other supraventricular arrhythmia.
- Take safety precautions if patient is dizzy or has other adverse CNS reactions.

## **PATIENT TEACHING**

- Advise patient to take donepezil only once per day just before going to bed.
- Inform her that drug may be taken with or without food.
- Tell patient prescribed oral disintegrating tablets not to swallow the tablet whole but to allow it to dissolve on the tongue and follow with a drink of water.
- Instruct patient to avoid hazardous activities, such as driving, until drug's CNS effects are known. Urge her to take safety precautions to prevent falling if she has adverse reactions, such as dizziness.
- Tell patient who has a history of gastric irritation or peptic ulcer disease that drug may aggravate these conditions by increasing gastric acid secretion.
- Advise women of childbearing age to notify prescriber if pregnancy is suspected or occurs.
- Alert patient that drug may cause decreased appetite, diarrhea, fatigue, insomnia, muscle cramps or spasms, nausea, or vomiting as some of the adverse reactions associated with drug use. Tell patient to notify prescriber if signs or symptoms are bothersome, persistent, or severe.

# dopamine hydrochloride

## Class and Category

*Pharmacologic class:* Adrenergic

*Therapeutic class:* Vasopressor

## Indications and Dosages

- *To correct hypotension due to inadequate cardiac output; to correct hemodynamic imbalances present in shock syndrome due to chronic cardiac decompensation, endotoxic speticemia, MI, open-heart surgery, renal failure, or trauma*

## I.V. INFUSION

**Adults.** *Initial:* 2 to 5 mcg/kg/min, increased gradually, as needed. *Usual:* Less than 20 mcg/kg/min.

**Adults who are more seriously ill.** *Initial:* 5 mcg/kg/min, increased gradually by 5 to 10 mcg/kg/min up to a rate of 20 to 50 mcg/kg/min, as needed.

***DOSAGE ADJUSTMENT*** Initial dosage reduced to 10% of usual amount if patient has taken MAO inhibitor in previous 2 to 3 wk.

Route	Onset	Peak	Duration
I.V.	In 5 min	Unknown	Up to 10 min

## Mechanism of Action

Stimulates dopamine<sub>1</sub> (D<sub>1</sub>) and dopamine<sub>2</sub> (D<sub>2</sub>) postsynaptic receptors. D<sub>1</sub> receptors causing vasodilation in cerebral, coronary, mesenteric, and renal blood vessels. D<sub>2</sub> receptors inhibit norepinephrine release. In higher doses, dopamine also stimulates alpha<sub>1</sub> and alpha<sub>2</sub> receptors, causing vascular smooth-muscle contraction.

It also causes increased renal blood flow, improved GFR, and increased urine output. At doses of 2 to 10 mcg/kg/min, dopamine stimulates beta<sub>1</sub>-adrenergic receptors, increasing cardiac output while maintaining dopaminergic-induced vasodilation. At doses of 10 mcg/kg/min or more, alpha-adrenergic agonism takes over, causing increased peripheral vascular resistance and renal vasoconstriction.

## Incompatibilities

Don't add dopamine to 5% sodium bicarbonate, alkaline I.V. solutions, iron salts or oxidizing agents.

## Contraindications

Hypersensitivity to dopamine or its components, pheochromocytoma, uncorrected ventricular fibrillation, ventricular tachycardia, and other tachyarrhythmias

## Interactions

### DRUGS

*alpha blockers:* Antagonized peripheral vasoconstriction with high doses of dopamine

*beta blockers:* Antagonized beta receptor-mediated inotropic effects of dopamine

*cyclopropane, halogenated hydrocarbon anesthetics:* Increased cardiac autonomic irritability with possible increased risk of hypertension and ventricular arrhythmias  
*diuretics:* Possibly increased diuretic effects of dopamine or diuretic  
*haloperidol:* Suppression of dopaminergic mesenteric vasodilation occurs with low rates of dopamine infusion  
*MAO inhibitors:* Prolonged and intensified cardiac stimulation and vasopressor effect  
*oxytocic drugs, other vasopressors, vasoconstricting agents:* Possibly severe persistent hypertension  
*phenytoin:* Possibly sudden bradycardia and hypotension  
*tricyclic antidepressants:* Possibly potentiated pressor response to dopamine

## **Adverse Reactions**

**CNS:** Anxiety, headache

**CV:** Angina, **atrial fibrillation, bradycardia, cardiac conduction abnormalities, ectopic beats**, hypertension, **hypotension**, palpitations, peripheral vasoconstriction, sinus tachycardia, **ventricular arrhythmias, widened QRS complex**

**GI:** Nausea, vomiting

**GU:** **Azotemia**

**RESP:** Dyspnea

**SKIN:** Extravasation with tissue necrosis, piloerection

## **Childbearing Considerations**

**PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LABOR & DELIVERY**

- Be aware that if a vasopressor drug such as dopamine is given during labor and delivery, an interaction with some oxytocic drugs may result in severe hypertension.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Due to critical nature of situation, breastfeeding would not be done during drug therapy.

## **Nursing Considerations**

- Avoid, if possible, giving dopamine to patients with occlusive vascular disease, such as atherosclerosis, Buerger's disease, diabetic endarteritis, or Raynaud's disease, because of risk of decreased peripheral circulation. Also, be aware that high doses of dopamine given for a prolonged period of time increase the risk of decreased peripheral circulation and could lead to gangrene in the patient's extremities.
- Use drug cautiously in patients with cardiac disease, particularly coronary artery disease, because dopamine increases myocardial oxygen demand. Also use drug cautiously in patients allergic to sulfites, which are contained in some forms of dopamine.
- Inspect parenteral solution for particles and discoloration before administration.
- Know that, when using the Viaflex Plus plastic container, the overwrap is a moisture and oxygen barrier. Do not remove unit from overwrap until ready for use. Be aware that a sulfur dioxide odor may occur upon removal of drug from the overwrap container. This does not pose a risk to the patient. Visually inspect the container. If the administration port protector is damaged, detached, or not present, discard container, because solution path sterility may be impaired.

- Dilute dopamine concentrate with a compatible I.V. solution before administering. Typical dilution is 400 mg in 250 ml to yield 1.6 mg/ml. Don't exceed 3.2 mg/ml.
- Ensure adequate fluid resuscitation before giving drug.
- Give drug by I.V. infusion using an infusion pump.

**WARNING** Know that when infusion rate exceeds 20 mcg/kg/min, monitor patient for excessive vasoconstriction and loss of renal vasodilating effects.

- Administer infusion through a central catheter to avoid extravasation and tissue necrosis. If drug must be given via peripheral line, inspect site often for signs of extravasation and necrosis. If such signs are detected, start a new I.V. line for dopamine infusion, discontinue previous I.V. line, and notify prescriber immediately.
- Expect to give 5 to 10 mg phentolamine diluted in 10 to 15 ml normal saline solution, as prescribed, if drug extravasates. Phentolamine infiltrates directly into area to antagonize vasoconstriction and minimize sloughing and tissue necrosis.
- Titrate dopamine gradually to minimize hypotension, especially after a high infusion rate.
- Monitor blood pressure continuously with an intra-arterial line, as indicated.
- Place patient on continuous ECG monitoring, and assess heart rate and rhythm for arrhythmias.
- Monitor patient's hemodynamic parameters, such as cardiac output, central venous pressure, and pulmonary artery wedge pressure, as indicated, to assess effectiveness of dopamine therapy.
- Monitor urine output hourly as appropriate to assess patient for improved renal blood flow.

## **PATIENT TEACHING**

- Explain the need for frequent hemodynamic monitoring.

# doravirine

## Pifeltro

### Class and Category

*Pharmacologic class:* Non-nucleoside reverse transcriptase inhibitor (NRTI)

*Therapeutic class:* Antiretroviral

### Indications and Dosages

- *As adjunct to treat human immunodeficiency virus (HIV-1) infection in patients with no prior antiretroviral treatment history; to replace the current antiretroviral regimen in patients who are virologically suppressed (HIV-1 RNA less than 50 copies/ml) on a stable antiretroviral regimen with no history of treatment failure and no known substitutions associated with resistance to doravirine*

### **TABLETS**

**Adults.** 100 mg once daily.

***DOSAGE ADJUSTMENT*** For patient taking rifabutin concomitantly, dosage increased to 100 mg twice daily and given about 12 hours apart.

### Mechanism of Action

Inhibits HIV-1 replication by noncompetitive inhibition of HIV-1 reverse transcriptase.

# Contraindications

Co-administration with carbamazepine, enzalutamide, mitotane, oxcarbazepine, phenobarbital, phenytoin, rifampin, rifapentine, or St. John's wort; hypersensitivity to doravirine or its components

# Interactions

## DRUGS

*CYP3A inducers such as carbamazepine, efavirenz, etravirine, enzalutamide, mitotane, nevirapine, oxcarbazepine, phenobarbital, phenytoin, rifabutin, rifampin, rifapentine, St. John's wort:* Decreased concentration of doravirine with decreased effectiveness  
*CYP3A inhibitors:* Possibly increased concentration of doravirine, increasing risk of adverse reactions

# Adverse Reactions

**CNS:** Abnormal dreams, depression, dizziness, fatigue, headache, insomnia, somnolence, **suicidal ideation**

**CV:** Elevated lipid levels

**GI:** Abdominal pain, diarrhea, elevated lipase and liver enzymes, nausea

**GU:** Elevated bilirubin and creatinine levels

**MS:** Elevated creatine kinase level

**SKIN:** Rash

**Other:** Elevated alkaline phosphatase, immune reconstitution syndrome

# Childbearing Considerations

## PREGNANCY

- Pregnancy exposure registry: 1-800-258- 4263.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## Nursing Considerations

- Obtain cholesterol and triglyceride levels before doravirine therapy is begun and periodically throughout therapy, because drug may cause an increase in lipid levels.
- Monitor patient's mood and emotional status, as doravirine may cause significant depression, mood changes, and suicidal ideation. Report any changes to prescriber.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including doravirine. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.

## PATIENT TEACHING

- Advise patient to avoid missing doses of doravirine. If she misses a dose, she should take it as soon as she remembers, but should not double the next dose or take more than prescribed.
- Instruct patient to alert prescriber of all medications taken, including over-the-counter products and any newly prescribed medication from other prescribers.

- Encourage women of childbearing age to report known or suspected pregnancy. If pregnancy occurs, encourage patient to enroll in the pregnancy exposure registry by calling 1-800-258-4263.
- Alert mothers that breastfeeding is not recommended during doravirine therapy.
- Instruct patient to report any persistent, severe, or unusual signs and symptoms.
- Tell patient or caregiver to report any signs of depression, mood changes, sleep disorders, or suicidal thoughts to prescriber.

## doripenem

### Doribax

## Class and Category

*Pharmacologic class:* Carbapenem

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat complicated intra-abdominal infections caused by Bacteroides caccae, B. fragilis, B. thetaiotaomicron, B. uniformis, B. vulgatus, Escherichia coli, Klebsiella pneumoniae, Peptostreptococcus micros, Pseudomonas aeruginosa, Streptococcus constellatus, or S. intermedius and complicated UTIs, including pyelonephritis caused by Acinetobacter baumannii, E. coli, K. pneumoniae, Proteus mirabilis, or P. aeruginosa*

## I.V. INFUSION

**Adults.** 500 mg infused over 1 hr every 8 hr for 5 to 14 days for complicated intra-abdominal infection and 10 days (possibly up to 14 days) for complicated UTI, including pyelonephritis. May switch to an appropriate oral therapy if improvement after 3 days.

**DOSAGE ADJUSTMENT** For patients with impaired renal function or creatinine clearance of 30 to 50 ml/min, dosage reduced to 250 mg infused over 1 hr every 8 hr. For creatinine clearance of 10 to 30 ml/min, dosage reduced to 250 mg infused over 1 hr every 12 hr.

Route	Onset	Peak	Duration
I.V.	Unknown	1 hr	8 hr

## Mechanism of Action

Inhibits cell wall synthesis in susceptible bacteria. Doripenem inactivates multiple penicillin-binding proteins essential in cell wall synthesis to cause cell death.

## Incompatibilities

Don't mix doripenem with other drugs or add to solutions containing other drugs because of potential for incompatibility.

## Contraindications

History of anaphylactic reactions to beta-lactams; hypersensitivity to doripenem, its components or other carbapenems

## Interactions

## DRUGS

*divalproex sodium, valproic acid*: Decreased effectiveness of valproic acid with possible loss of seizure control

*probenecid*: Increased plasma concentrations of doripenem

## Adverse Reactions

**CNS:** Headache, seizures

**CV:** Phlebitis

**EENT:** Oral candidiasis

**GI:** Diarrhea, elevated liver enzyme, nausea

**GU:** **Renal failure or impairment**, vaginitis

**HEME:** **Leukopenia, neutropenia, thrombocytopenia**

**RESP:** **Interstitial pneumonia**

**SKIN:** Dermatitis, erythema, **erythema multiforme**, macular or papular eruptions, pruritus, rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cautiously in patients with a history of hypersensitivity to cephalosporins or penicillins because cross-sensitivity may occur.
- Constitute vial with 10 ml sterile water for injection or normal saline solution, and gently shake to form a suspension. Withdraw suspension using a syringe with a 21G needle and add it to an infusion bag containing 100 ml normal saline solution or 5% dextrose. Gently shake until clear. If administering reduced dosage of 250 mg, remove 55 ml of prepared solution from infusion bag and discard before infusion.
- Be aware that upon constitution, suspension in the vial must be diluted within 1 hour. Once drug is diluted in infusion solution, drug stored at room temperature must be used within 8 hours if mixed in normal saline solution and within 4 hours if mixed in 5% dextrose. If infusion solution is refrigerated, it must be used within 24 hours or discarded.
- Monitor patient closely for evidence of hypersensitivity, especially if patient has multiple allergies, because serious and occasionally fatal hypersensitivity reactions have occurred in patients receiving beta-lactam antibiotics. If an allergic reaction occurs, discontinue drug immediately, notify prescriber, and expect to administer emergency treatment as ordered, and provide airway management.
- Assess patient's bowel pattern daily; severe diarrhea may be caused by *Clostridium difficile*. If suspected, expect to stop drug and provide treatment as prescribed.

## PATIENT TEACHING

- Instruct patient to report any evidence of allergic reaction, such as hives, itching, rash, or trouble breathing.
- Advise patient to report diarrhea if severe or persistent.

**doxazosin mesylate**

# Apo-Doxazosin (CAN), Cardura, Cardura XL

## Class and Category

*Pharmacologic class:* Alpha blocker

*Therapeutic class:* Antihypertensive, benign prostatic hyperplasia therapeutic agent

## Indications and Dosages

➤ *To manage hypertension*

### **TABLETS**

**Adults.** *Initial:* 1 mg daily titrated upwards to maximum dosage to achieve desired blood pressure, as needed.

*Maximum:* 16 mg daily.

➤ *To treat benign prostatic hyperplasia (BPH)*

### **TABLETS**

**Adults.** *Initial:* 1 mg daily. Doubled every 1 to 2 wk, if needed, based on signs and symptoms. *Maximum:* 8 mg daily

### **E.R. TABLETS**

**Adults.** *Initial:* 4 mg daily, increased to 8 mg after 3 to 4 wk, as needed.

Route	Onset	Peak	Duration
P.O.	1-2 hr*	2-6 hr <sup>†</sup>	24 hr <sup>†</sup>

- \* For hypertension; in 2 wk for BPH.
- † For hypertension; unknown for BPH.

## Mechanism of Action

Competitively inhibits  $\alpha_1$ -adrenergic receptors in the sympathetic nervous system, causing peripheral vasodilation and reduced peripheral vascular resistance. This action decreases blood pressure, especially when the patient stands. Doxazosin also relaxes smooth muscle of the bladder neck, prostate, and prostate capsule, which reduces urethral resistance and pressure and urinary outflow resistance.

## Contraindications

Hypersensitivity to doxazosin, other quinazolines such as prazosin or terazosin, or their components

## Interactions

### DRUGS

*diuretics, phosphodiesterase-5 inhibitors, other antihypertensives, strong CYP3A4 inhibitors:* Enhanced hypotensive effects

## Adverse Reactions

**CNS:** Dizziness, drowsiness, headache, nervousness, restlessness, vertigo

**CV:** **Arrhythmias**, first-dose orthostatic hypotension, palpitations, peripheral edema, sinus tachycardia

**EENT:** Intraoperative floppy iris syndrome, rhinitis

**GI:** GI obstruction, nausea

**GU:** Priapism

**RESP:** Dyspnea

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug may be present in breast milk.
- Patient should check with prescriber before breastfeeding if prescribed immediate release form. Extended release form is not used to treat women.

## Nursing Considerations

- Know that drug should not be given to hypotensive patients.
- Be aware that Cardura XL is not for use in female patients and is not to be used to treat hypertension.
- Use doxazosin cautiously in patients with hepatic disease (because normal dosage may cause exaggerated effects) and in elderly patients (because hypotensive response may be more pronounced).

**WARNING** Monitor patient for orthostatic hypotension (which may cause syncope) early in therapy, especially after exercise and in patients with hypovolemia.

- Monitor blood pressure for 2 to 6 hours after first dose and with each increase because orthostatic hypotension commonly occurs at this time.

Adjust dose as prescribed, based on standing blood pressure.

- Carefully monitor patients with renal disease for exaggerated effects, such as first-dose orthostatic hypotension.
- Monitor urination, checking for difficulty urinating and urine retention, to assess drug's effects on BPH.

## PATIENT TEACHING

- Inform patient that he may take doxazosin in the morning or evening and with food, if desired.
- Instruct patient to change position slowly to minimize orthostatic hypotension.
- Advise patient to avoid exercising, going outside in hot weather, standing for long periods, and using alcohol; these activities may worsen orthostatic hypotension.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Tell patient to inform surgeon that he is taking doxazosin therapy if cataract surgery is required because drug may cause intraoperative floppy iris syndrome with this procedure.
- Inform the patient taking drug for benign prostatic hyperplasia that he may become dizzy or faint if he takes an oral erectile dysfunction medicine during doxazosin therapy. Therefore, he should not use an oral erectile dysfunction medicine until he has discussed its use with the prescriber. Also alert him to the rare possibility of developing a painful penile erection caused by doxazosin therapy that could last for hours and requires immediate medical attention, if it occurs.

# doxepin hydrochloride

## Silenor

## Class and Category

*Pharmacologic class:* Tricyclic antidepressant  
*Therapeutic class:* Antidepressant

## Indications and Dosages

- *To treat mild to moderate depression or anxiety*

### CAPSULES, ORAL SOLUTION

**Adults.** 25 to 50 mg daily in divided doses daily or once daily and could be at bedtime. *Maximum:* 150 mg daily.

- *To treat very mild depression or anxiety accompanying organic disease*

### CAPSULES, ORAL SOLUTION

**Adults.** 75 to 150 mg in divided doses daily or once daily at which could be bedtime. *Maximum:* 150 mg daily.

- *To treat severe depression or anxiety*

### CAPSULES, ORAL SOLUTION

**Adults.** 50 mg three times daily, gradually increased to 300 mg daily, as needed. *Maximum:* 300 mg daily.

- *To treat insomnia characterized by difficulty with sleep maintenance*

### TABLET (SILENOR)

**Adults.** 3 to 6 mg within 30 min of bedtime. *Maximum:* 6 mg daily.

***DOSAGE ADJUSTMENT*** For elderly patients age 65 and over taking Silenor, dosage reduced to 3 mg within 30 min of bedtime but may be increased to 6 mg daily, as needed.

---

**Route**

**Onset**

**Peak**

**Duration**

Route	Onset	Peak	Duration
P.O.	2-3 wk	Unknown	Unknown

## Mechanism of Action

May block norepinephrine and serotonin reuptake by adrenergic nerves. In this way, the tricyclic antidepressant raises norepinephrine and serotonin levels at nerve synapses, which may elevate mood and reduce depression. It is unknown how doxepin maintains sleep, but is thought to be due to its antagonism of the H1 receptor.

## Incompatibilities

Don't mix doxepin solution with carbonated beverages or grape juice.

## Contraindications

Hypersensitivity to doxepin, other tricyclic antidepressants, or their components; severe urinary retention; untreated narrow-angle glaucoma; use of MAO inhibitor within 14 days

## Interactions

### DRUGS

*cimetidine, flecainide, other tricyclic antidepressants, phenothiazines, propafenone, quinidine, selective serotonin reuptake inhibitors:* Increased blood doxepin level from inhibited systemic clearance, resulting in increased risk of toxicity

*CNS depressants, sedating antihistamines:* Possibly potentiated CNS depression, hypotension, and respiratory depression

*MAO inhibitors:* Possibly hyperpyrexia, hypertension, seizures, and death

*tolazamide:* Possibly severe hypoglycemia

## **ACTIVITIES**

*alcohol use:* Possibly enhanced CNS depression, hypotension, and respiratory depression

## **Adverse Reactions**

**CNS:** Confusion, delirium, dream disturbances, drowsiness, fatigue, hallucinations, headache, nervousness, Parkinsonism, restlessness, sedation, **seizures, suicidal ideation (especially teens)**, tremor

**CV:** **ECG changes**, orthostatic hypotension, palpitations

**EENT:** Blurred vision, dry mouth, taste perversion

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Constipation, diarrhea, heartburn, ileus, increased appetite, jaundice, nausea, vomiting,

**GU:** Decreased libido, ejaculation disorders

**SKIN:** Diaphoresis

**Other:** Weight gain

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding, especially if taking higher doses of the drug, because apnea and drowsiness may occur in the breastfed infant.

## Nursing Considerations

- Mix oral solution in 120 ml of juice such as grapefruit, orange, pineapple, or tomato; milk; or water, if desired.
- Expect to observe adverse reactions within a few hours after giving drug.
- Evaluate patient for therapeutic response, such as decreased anxiety, apprehension, depression, fear, guilt, somatic symptoms, and worry; increased energy; and more restful sleep.

**WARNING** Monitor patients, especially young adults, closely for evidence of suicidal thinking and behavior because doxepin increases the risk in this group of suicidal thinking.

- Keep in mind that abrupt withdrawal of doxepin after prolonged therapy can cause cholinergic rebound effects, including diarrhea, nausea, and vomiting.
- Plan to discontinue drug, as prescribed, several days before elective surgery to avoid hypertension.
- Monitor elderly patients for Parkinsonism, especially with high-dose therapy.
- Be alert for seizures. Patients with seizure disorder may need increased anticonvulsant dosage to maintain seizure control.
- Know that for patients with asthma or sulfite sensitivity, doxepin tablets may aggravate asthma or cause allergic reactions because they contain sulfites.

- Follow diabetic patient's serum glucose level closely; drug may alter glucose metabolism.

## **PATIENT TEACHING**

**WARNING** Alert parents of young adults to watch them closely for abnormal thinking or behavior and increased aggression or hostility. Emphasize importance of notifying prescriber about unusual changes.

- Instruct patient to avoid alcohol during doxepin therapy because mental alertness may decrease.
- Advise diabetic patient to measure serum glucose level more often than usual.

## **doxycycline**

**Oracea**

## **doxycycline calcium**

***(contains 50 mg of base per 5 ml of oral suspension)***

**Vibramycin**

## **doxycycline hyclate**

***(contains 50 or 100 mg of base per capsule, 100 mg of base per delayed-release capsule, 100 mg of base per***

***tablet, and 100 or 200 mg of base per injection vial)***

**Acticlate, Acticlate CAP, Alti-Doxycycline (CAN), Apo-Doxy (CAN), Atridox, Doryx, Doryx MPC, Doxycin (CAN), Lymepak, Vibramycin**

**doxycycline monohydrate**

***(contains 50 or 100 mg of base per capsule and 25 mg of base per 5 ml of oral suspension)***

**Monodox**

## **Class and Category**

*Pharmacologic class:* Tetracycline

*Therapeutic class:* Antibiotic

➤ *To treat inhalation anthrax post exposure*

## **CAPSULES, ORAL SUSPENSION, SYRUP, TABLETS**

**Adults and children age 8 and over weighing 45 kg (99 lb) or more.** 100 mg (120 mg Doryx MPC) twice daily for 60 days.

**Children age 8 and over weighing less than 45 kg (99 lb).** 2.2 mg/kg (2.6 mg/kg Doryx MPC) twice daily for 60 days.

- *To treat inflammatory lesions (papules and pustules) of rosacea*

## **E.R. CAPSULES (ORACEA)**

**Adults.** 40 mg once daily in morning

- *To treat endocervical, rectal, and urethral infections caused by Chlamydia trachomatis*

## **CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, SYRUP, TABLETS**

**Adults.** 100 mg (120 mg Doryx MPC) twice daily for 7 days.

- *To treat uncomplicated gonococcal infections except anorectal infections in men*

## **CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, SYRUP, TABLETS**

**Adults.** 100 mg (120 mg Doryx MPC) twice a day for 7 days. Alternatively, 300 mg (360 mg Doryx MPC) followed in 1 hr by a second 300 mg (360 mg Doryx MPC) dose.

- *To treat epididymo-orchitis caused by C. trachomatis or Neisseria gonorrhoeae*

## **CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, SYRUP, TABLETS**

**Adults.** 100 mg (120 mg Doryx MPC) twice daily for at least 10 days.

- *To prevent malaria*

## **CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, SYRUP, TABLETS**

**Adults.** 100 mg (120 mg Doryx MPC) daily starting 1 to 2 days before travel, continued daily during travel, and then daily for 4 wk after travel ends.

**Children over age 8.** 2 mg/kg (2.4 mg/kg Doryx MPC) daily starting 1 to 2 days before travel, continued daily during travel, and daily for 4 wk after travel ends.

➤ *To treat early syphilis in penicillin-allergic patients*

### **CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, SYRUP, TABLETS**

**Adults.** 100 mg (120 mg Doryx MPC) twice daily for 2 wk.

➤ *To treat syphilis of more than 1 year duration in penicillin-allergic patients*

### **CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, SYRUP, TABLETS**

**Adults.** 100 mg (120 mg Doryx MPC) twice daily for 4 wk.

➤ *To treat early Lyme disease*

### **TABLETS (LYMEPAK)**

**Adults and children age 8 years and over weighing 45 kg (99 lb) or more.** 100 mg every 12 hr for 21 days.

➤ *To treat all other infections caused by susceptible organisms*

### **CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, SYRUP, TABLETS**

**Adults and children over age 8 weighing 45 kg (99 lb) or more.** 100 mg (120 mg Doryx MPC) every 12 hr on day 1 and then 100 mg (120 mg Doryx MPC) once daily or 50 mg (base) twice daily. For severe infections, 100 mg continued every 12 hr.

**Children over age 8 weighing less than 45 kg (99 lb).**

2.2 mg/kg (2.6 mg/kg Doryx MPC) twice daily on day 1 and then 2.2 to 4.4 mg/kg (2.6 mg/kg Doryx MPC) once daily or 1.1 to 2.2 mg/kg (1.3 mg/kg Doryx MPC) twice daily.

## **I.V. INFUSION**

**Adults and children over age 8 weighing more than 45 kg.** 200 mg once daily or 100 mg every 12 hr on day 1 and then 100 to 200 mg once daily or 50 to 100 mg every 12 hr. I.V. infused slowly over 1 hr.

**Children weighing 45 kg (99 lb) or less.** 4.4 mg/kg once daily or 2.2 mg/kg every 12 hr on day 1 and then 2.2 to 4.4 mg/kg once daily or 1.1 to 2.2 mg/kg every 12 hr. I.V. infused slowly over 1 hr.

## **Mechanism of Action**

Exerts a bacteriostatic effect against a wide variety of gram-positive and gram-negative organisms. Doxycycline is more lipophilic than other tetracyclines, which allows it to pass more easily through the bacterial lipid bilayer, where it binds reversibly to 30S ribosomal subunits. Bound doxycycline blocks the binding of aminoacyl transfer RNA to messenger RNA, thus inhibiting bacterial protein synthesis.

## **Contraindications**

Hypersensitivity to doxycycline, other tetracyclines, or their components

## **Interactions**

## **DRUGS**

*antacids that contain aluminum, calcium, magnesium, or zinc; calcium supplements; choline and magnesium salicylates; iron-containing preparations, laxatives that contain magnesium:* Decreased doxycycline absorption and effects

*barbiturates, carbamazepine, phenytoin:* Increased clearance and decreased effects of doxycycline

*methoxyflurane:* Increased risk of severe or fatal renal toxicity

*oral anticoagulants:* Possibly increased hypoprothrombinemic effects of these drugs

*oral contraceptives:* Decreased effectiveness of estrogen-containing oral contraceptives, increased risk of breakthrough bleeding

*penicillin:* Possibly interference with bactericidal action of penicillin

## **Adverse Reactions**

**CNS:** Headache, **intracranial hypertension**, paresthesia

**CV:** **Pericarditis**, phlebitis

**EENT:** Black “hairy” tongue, glossitis, hoarseness, oral candidiasis, pharyngitis, stomatitis, tooth discoloration, visual disturbances

**GI:** Anorexia; bulky, loose stools; diarrhea; dysphagia; enterocolitis; epigastric distress; esophageal ulceration; esophagitis; **hepatotoxicity**, inflammatory lesions in anogenital region; nausea; **pancreatitis**; **pseudomembranous colitis**; rectal candidiasis; vomiting

**GU:** Anogenital lesions, dark yellow or brown urine, elevated BUN level, vaginal candidiasis

**HEME:** Eosinophilia, **hemolytic anemia**, **neutropenia**, **thrombocytopenia**, **thrombocytopenic purpura**

**SKIN:** Dermatitis, **erythema multiforme**, erythematous and maculopapular rashes, **exfoliative dermatitis**, photosensitivity, rash, skin hyperpigmentation, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, exacerbation of systemic lupus erythematosus, injection-site phlebitis, Jarisch–Herxheimer (systemic inflammatory response) reaction in presence of spirochete infections, serum sickness

## Childbearing Considerations

### PREGNANCY

- Drug causes fetal harm, especially retardation of skeleton and tooth development.
- Drug is not recommended for use during pregnancy unless absolutely necessary and there is no alternative drug therapy available.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Avoid giving doxycycline to breastfeeding women because of the risk of enamel hypoplasia, inhibited linear skeletal growth, oral and vaginal

candidiasis, photosensitivity reactions, and tooth discoloration in breastfeeding infant.

- Avoid giving drug to children age 8 and under, if possible; it may cause discoloration and enamel hypoplasia of developing teeth that may be permanent.
- Be aware that Doryx and Doryx MPC are not interchangeable. Doryx 100 mg equals 120 mg of Doryx MPC.
- Use oral suspension cautiously in patients allergic to sulfites because it contains sodium metabisulfite.
- Expect to adjust dosage for patients who have hepatic disease to avoid drug accumulation.

**WARNING** Don't give doxycycline by I.M. or subcutaneous route.

- Give doxycycline without regard to meals. Food and milk may delay absorption, but they don't significantly reduce it.
- Observe patient often for injection-site phlebitis, a common adverse reaction to I.V. administration.
- Monitor liver function test results as appropriate to detect hepatotoxicity.
- Expect oral or parenteral doxycycline to increase risk of oral, rectal, or vaginal candidiasis—especially in debilitated or elderly patients and those on prolonged therapy—by changing the normal balance of microbial flora.

**WARNING** Monitor patient for signs and symptoms of intracranial hypertension, such as blurred vision, diplopia, headache, and vision loss; papilledema may be seen on fundoscopy. Patients at greater risk include women of childbearing age who are overweight or have a history of intracranial hypertension. If patient complains of visual changes, notify prescriber to obtain an immediate ophthalmologic evaluation because permanent visual loss can occur. Be aware that intracranial pressure may remain elevated for weeks after doxycycline therapy has been discontinued and warrants close follow-up.

- Monitor patient closely for diarrhea, which may indicate pseudomembranous colitis. If diarrhea occurs, notify prescriber and expect to withhold doxycycline. Expect to treat pseudomembranous colitis with electrolytes, fluids, protein, and an antibiotic effective against *Clostridium difficile*.
- Monitor patient for adverse skin reactions, because doxycycline has caused severe skin reactions that could be life-threatening. Notify prescriber as soon as possible if skin adverse reactions occur, provide supportive care, as ordered, and expect drug to be discontinued.

## PATIENT TEACHING

- Instruct patient not to take doxycycline just before bed because it may not dissolve properly when she's recumbent and may cause esophageal burning and ulceration.
- Instruct patient taking doxycycline for rosacea to take the capsule in the morning on an empty stomach with a full glass of water. However, if gastric irritation occurs, tell patient to take with food.
- Advise patient to avoid antacids containing aluminum, calcium, or magnesium
- Instruct patient to drink plenty of fluids while taking doxycycline to reduce the risk of esophageal burning and ulceration.
- Inform patient that her urine may become dark yellow or brown during therapy.
- Urge patient to avoid sun exposure and ultraviolet light as much as possible during therapy and to use sunscreen or sunblock as needed. If patient develops phototoxicity, such as skin eruption, tell her to stop drug and notify prescriber.
- Tell patient to notify prescriber if skin adverse reactions occur, because reactions may become severe and drug may have to be discontinued.
- Advise patients who take an oral contraceptive to use an additional contraceptive method during therapy. Also advise all women of childbearing age to notify prescriber immediately if pregnancy occurs or is suspected, as drug may cause retardation of skeletal development in the fetus.
- Know that if patient is being treated for a sexually transmitted disease, her partner may need treatment as well.

- Tell patient to notify prescriber immediately about anorexia, epigastric distress, nausea, or vomiting as well as any visual changes during therapy.
- Urge patient to report bloody, watery stools to prescriber immediately, even up to 2 months after drug therapy has ended.
- Alert female patients that doxycycline may increase risk of vaginal candidiasis. Tell her to notify prescriber if she develops vaginal discharge or itching.
- Inform mothers wishing to breastfeed their infant during doxycycline therapy that it is not recommended because effects are unknown.
- Advise patient prescribed Lymepak to notify prescriber if fever, intensification of skin rash, and shaking chills occurs, a systemic reaction known as Jarisch-Herxheimer reaction. Reassure patient that symptoms usually resolve within several hours with fluid intake and antipyretic treatment.

## dronabinol

(delta-9-tetrahydro-cannabinol,  
THC)

**Marinol, Syndros**

### **Class, Category, and Schedule**

*Pharmacologic class:* Cannabinoid

*Therapeutic class:* Antiemetic, appetite stimulant

*Controlled substance schedule:* II (Syndros), III (Marinol)

### **Indications and Dosages**

- *To prevent nausea and vomiting caused by chemotherapy and unresponsive to other antiemetics*

## **CAPSULES (MARINOL)**

**Adults.** 5 mg/m<sup>2</sup> 1 to 3 hr before chemotherapy on an empty stomach and then every 2 to 4 hr after chemotherapy for a total of 4 to 6 doses daily, increased by 2.5 g/m<sup>2</sup> increments, as needed. *Maximum:* 15 mg/m<sup>2</sup>/dose for a total of 4 to 6 doses daily.

## **ORAL SOLUTION (SYNDROS)**

**Adults.** 4.2 mg/m<sup>2</sup> 1 to 3 hr before chemotherapy on an empty stomach and then every 2 to 4 hr after chemotherapy for a total of 4 to 6 doses daily, increased, as needed, in increments of 2.1 mg/m<sup>2</sup>. *Maximum:* 12.6 mg/m<sup>2</sup> per dose for 4 to 6 doses daily.

**DOSAGE ADJUSTMENT** For elderly patients prescribed Marinol, initial dosage may be reduced to 2.5 mg/m<sup>2</sup> 1 to 3 hr before chemotherapy to reduce CNS adverse reactions. For elderly patients prescribed Syndros and all patients who experience persistent or severe adverse reactions, dosage reduced to 2.1 mg/m<sup>2</sup> 1 to 3 hr before chemotherapy.

➤ *To stimulate appetite in AIDS patients*

## **CAPSULES (MARINOL)**

**Adults.** *Initial:* 2.5 mg twice daily 1 hr before lunch and dinner, increased as needed. *Maximum:* 10 mg daily in divided doses.

## **ORAL SOLUTION (SYNDROS)**

**Adults.** 2.1 mg twice daily, 1 hr before lunch and 1 hr before dinner.

**DOSAGE ADJUSTMENT** Dosage for capsule form (Marinol) reduced to 2.5 mg before supper or at bedtime for the elderly and patients who can't tolerate 5 mg daily. Dosage

maintained for oral solution form (Syndros) at 2.1 mg, but dosage frequency reduced to once daily 1 hr before dinner or bedtime in the elderly and patients who can't tolerate a twice-daily dosage.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	24 hr or longer*

\* For appetite stimulant effects; unknown for antiemetic effects.

## Mechanism of Action

May exert antiemetic effect by inhibiting the vomiting control mechanism in the medulla oblongata. As the main psychoactive substance in marijuana (*Cannabis sativa* L.), dronabinol's effects may be mediated by cannabinoid receptors in neural tissues.

## Contraindications

*For Marinol:* Hypersensitivity to dronabinol, its components, other cannabinoids, or sesame oil; *For Syndros:* Hypersensitivity reaction to dronabinol, its components, or alcohol; use of disulfiram- or metronidazole-containing products within past 14 days

## Interactions

### DRUGS

*amphotericin B, cyclosporine, warfarin, other drugs highly bound to plasma proteins with a narrow therapeutic index:* Possibly increased risk of adverse reactions associated with these drugs

*CNS depressants (such as benzodiazepines), sedatives, tricyclic antidepressants: Additive CNS effects*  
*CYP2C9 inhibitors such as amiodarone, CYP2C9 and CYP3A4 inducers: Possibly decreased dronabinol exposure and effectiveness fluconazole; CYP3A4 inhibitors such as clarithromycin, erythromycin, itraconazole, ketoconazole, ritonavir: Possibly increased dronabinol-related adverse reactions from increased exposure*  
*disulfiram, metronidazole (Syndros only): Possible disulfiram-like reaction*

## **ACTIVITIES**

*alcohol use: Additive CNS depressant effects*

## **Adverse Reactions**

**CNS:** Altered mental state, amnesia, asthenia, anxiety, ataxia, chills, cognitive impairment, confusion, delirium, delusions, depersonalization, depression, disorientation, dizziness, drowsiness, euphoria, exacerbation of mania or schizophrenia, fatigue, hallucinations, headache, insomnia, irritability, loss of consciousness, malaise, mood changes, movement disorder, nervousness, nightmares, panic attack, paranoid reaction, **seizures**, sleep disturbance, speech difficulties, somnolence, syncope

**CV:** Orthostatic hypotension, palpitations, sinus tachycardia, vasodilation

**EENT:** Lip swelling, oral lesions, rhinitis, sinusitis, throat tightness, tinnitus, vision difficulties

**GI:** Abdominal pain, anorexia, diarrhea, elevated liver enzymes, fecal incontinence, nausea, vomiting

**MS:** Myalgias

**RESP:** Cough

**SKIN:** Diaphoresis, disseminated rash, facial flushing, skin burning, urticaria

**Other:** Physical and psychological dependence

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm such as fetal growth restriction, low birth weight, preterm birth, small for gestational age, and stillbirth.
- Drug use should be avoided in pregnant women.

### LACTATION

- Drug may be present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.
- Mothers receiving drug for treatment of nausea and vomiting related to cancer chemotherapy should not breastfeed during treatment and for 9 days after the last dose.

## Nursing Considerations

**WARNING** Know that dronabinol shouldn't be discontinued abruptly; if it is, withdrawal syndrome may occur.

- Be aware that patients should be screened for depression, mania, and schizophrenia prior to treatment, because dronabinol can exacerbate these conditions. Use with extreme caution, if usage cannot be avoided, in these patients. Monitor patient for new or worsening psychiatric symptoms during therapy. Also know that concomitant use with other drugs associated with similar psychiatric effects should be avoided.

- Be aware that oral solution contains alcohol, which can produce disulfiram-like reactions when co-administered with disulfiram or other drugs that produce this reaction. Know that these products should be discontinued at least 14 days before starting oral solution form of dronabinol and not administered for at least 7 days after therapy with dronabinol has ceased.
- Use cautiously in patients with history of seizures because drug may lower seizure threshold. Notify prescriber of seizures immediately, and expect to stop drug.
- Be aware that patients with a history of substance abuse or dependence are at higher risk for abusing dronabinol. Assess patient's risk for abuse or misuse prior to dronabinol therapy and monitor patient throughout for evidence of abuse or misuse.
- Be aware that patients under age 45 may tolerate drug better than those over age 45.
- Be aware that liquid solution of dronabinol may be administered by a feeding tube that is silicone only and equal to or greater than a 14 French. Tubes consisting of polyurethane should not be used. Draw up the prescribed dose of drug using the calibrated dosing syringe packaged with drug. If dose is greater than 5 mg, divide the total dose into 2 or more portions using oral syringe. After administering drug via feeding tube, flush feeding tube with 30 ml of water using a catheter-tip syringe.
- Anticipate higher risk of cardiovascular reactions, such as blood pressure changes (especially orthostatic hypotension) and increased heart rate, at higher doses and in patients with cardiac conditions. Monitor patient's vital signs closely, especially when drug is initiated or when dosage is increased.

**WARNING** Expect tolerance to drug to develop over time, especially if patient has smoked marijuana.

- Be aware that short-term, low-dose therapy doesn't typically lead to physical and psychological dependence, which may occur with long-term, high-dose therapy.
- Alert prescriber if patient experiences changes in mental state or cognitive impairment, because dosage will have to be reduced or drug discontinued. Know that elderly patients may be more sensitive to the neurological and psychoactive effects of dronabinol.
- Expect drug to alter REM sleep pattern, even after therapy stops.

- Be aware that oral solution contains alcohol, which can produce disulfiram-like reactions when co-administered with disulfiram or other drugs that produce this reaction. Know that these products should be discontinued at least 14 days before starting oral solution form of dronabinol and not administered for at least 7 days after therapy with dronabinol has ceased.
- Be aware that paradoxical abdominal pain, nausea, and vomiting can occur with chronic, long-term use of dronabinol.

## **PATIENT TEACHING**

- Caution patient not to stop drug abruptly because withdrawal symptoms may occur.
- Instruct patient to take dronabinol with a full glass of water (6 to 8 ounces).
- Urge patient not to use alcohol while taking dronabinol because it may enhance CNS depression.
- Instruct patient to rise slowly to sitting or standing position to minimize effects of orthostatic hypotension.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Inform patient that sleep pattern may be adversely affected during therapy and for sometime afterward.
- Inform women of childbearing age to notify prescriber if pregnancy is known or suspected, because dronabinol may cause fetal harm. Also advise mothers not to breastfeed.
- Monitor elderly patients closely, especially if dementia is present, because they may be more sensitive to the neuropsychiatric and postural hypotensive effects of the drug and be at increased risk of falls.

**dronedarone**

**Multaq**

# Class and Category

*Pharmacologic class:* Benzofuran derivative

*Therapeutic class:* Antiarrhythmic

## Indications and Dosages

- *To reduce risk of hospitalization for atrial fibrillation in patients in sinus rhythm with a history of paroxysmal or persistent atrial fibrillation*

### **TABLETS**

**Adults.** 400 mg twice daily, with morning and evening meals

Route	Onset	Peak	Duration
P.O.	Unknown	3–6 hr	Unknown

## Mechanism of Action

Although specific effect on heart rhythm is unknown, dronedarone possesses properties of all four Vaughn-Williams antiarrhythmic classes.

## Contraindications

Bradycardia less than 50 beats/minute; breastfeeding; concurrent use of drugs or herbal products that prolong QT interval, such as class I and III antiarrhythmics, phenothiazine antipsychotics, oral macrolide antibiotics (selected), and tricyclic antidepressants or strong CYP3A inhibitors, such as clarithromycin, cyclosporine, ketoconazole, itraconazole, nefazodone, ritonavir, telithromycin, and voriconazole; hypersensitivity to

dronedarone or its components; liver or lung toxicity related to previous use of amiodarone; pregnancy; PR interval greater than 280 msec or QTc Bazett interval of 500 msec or more; permanent atrial fibrillation; second- or third-degree atrioventricular block or sick-sinus syndrome (except when used with a functioning pacemaker); severe hepatic impairment (Child-Pugh class C); symptomatic heart failure with recent decompensation requiring hospitalization or NYHA Class IV symptoms

## Interactions

### DRUGS

*beta blockers*: Increased risk of bradycardia

*calcium channel blockers*: Possibly increased dronedarone effects on conduction

*calcium channel blockers, such as diltiazem, nifedipine, and verapamil; CYP3A substrates with narrow therapeutic range such as sirolimus and tacrolimus; CYP2D6*

*substrates, such as beta blockers, selective serotonin reuptake agents, and tricyclic antidepressants; statins, such as simvastatin*: Increased effects of these drugs with possibly increased risk of adverse reactions

*class I and III antiarrhythmics, macrolide antibiotics, phenothiazines, tricyclic antidepressants*: Possibly increased QT interval

*CYP3A inducers, such as carbamazepine, phenobarbital, phenytoin, rifampin, St. John's wort*: Decreased dronedarone effects

*CYP3A inhibitors, such as clarithromycin, cyclosporine, ketoconazole, itraconazole, nefazodone, ritonavir, telithromycin, and voriconazole*: Increased dronedarone effects

*digoxin and other P-gp substrates such as dabigatran:*  
Increased effect of these drugs with risk of toxicity  
*warfarin:* Possible increased risk of bleeding and INR

## **FOODS**

*grapefruit juice:* Increased dronedarone effects

## **Adverse Reactions**

**CNS:** Asthenia

**CV:** Bradycardia, heart failure, prolonged QT interval, vasculitis

**GI:** Abdominal pain, diarrhea, dyspepsia, liver injury, nausea, vomiting

**GU:** Increased serum creatinine levels

**RESP:** Dyspnea, interstitial lung disease such as pneumonitis and pulmonary fibrosis, nonproductive cough, pulmonary toxicity

**SKIN:** Allergic dermatitis, dermatitis, eczema, photosensitivity, pruritus, rash

**Other:** Anaphylaxis, angioedema, hypokalemia, hypomagnesemia

## **Childbearing Considerations**

### **PREGNANCY**

- Drug may cause fetal harm.
- Drug is contraindicated in women who are or who may become pregnant during drug therapy.

## LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Check that patient has stopped taking any drug contraindicated with dronedarone, as prescribed, before giving first dose. Also check that patient is receiving appropriate antithrombotic therapy prior to giving first dose because patients are at increased risk for stroke, especially in the first 2 weeks of therapy. In addition, check patient's serum potassium and magnesium levels prior to initiating therapy and throughout therapy because of increased risk of deficiency and arrhythmias, especially if patient is also taking a potassium-depleting diuretic.
- Assess patient for evidence of heart failure, such as dependent edema, increasing shortness of breath, or weight gain. If present, notify prescriber; dronedarone may need to be discontinued.
- Review patient's electrocardiogram at least once every 3 months, as ordered to determine patient's rhythm. If atrial fibrillation is found, prepare patient for cardioversion, as ordered or expect dronedarone therapy to be discontinued. Monitor patient's PR and QT interval, as ordered, to see if conduction is delayed. If so, notify prescriber immediately. Dronedarone will have to be stopped.
- Monitor patient's serum creatinine levels, as ordered. Elevation may occur rapidly, plateau after 7 days, and usually is reversible after therapy stops.
- Monitor patient's liver function, as ordered, because severe liver injury may occur with dronedarone therapy. If liver enzymes become elevated or the patient develops symptoms of liver dysfunction such as anorexia, dark urine, fatigue, fever, itching, jaundice, malaise, nausea, right upper quadrant pain, or vomiting, notify prescriber and expect drug to be discontinued immediately.
- Monitor patient for dyspnea or nonproductive cough as possible development of pulmonary toxicity. If confirmed, expect drug to be discontinued.

## PATIENT TEACHING

- Inform patient that dronedarone must be taken with a meal.
- Warn patient that dronedarone should not be taken with grapefruit juice.
- Urge patient to contact prescriber if he develops evidence of heart failure, such as dependent edema, increasing shortness of breath or weight gain, because dronedarone may need to be discontinued.
- Inform women of childbearing age of need for contraception if sexually active because drug is contraindicated during pregnancy and breastfeeding. If pregnancy occurs, she should notify prescriber immediately.
- Tell patient to inform all prescribers that she is taking dronedarone and to check with prescriber before taking any herbal product with dronedarone, newly prescribed drug, or OTC product.
- Review symptoms of liver dysfunction with patient and urge her to seek immediate medical attention, if present, and to stop taking dronedarone.

## droxidopa

### Northera

## Class and Category

*Pharmacologic class:* Norepinephrine prodrug

*Therapeutic class:* Vasoconstrictor

## Indications and Dosages

- *To treat symptomatic neurogenic orthostatic hypotension caused by dopamine beta-hydroxylase deficiency, nondiabetic autonomic neuropathy, and primary autonomic failure seen in multiple-system*

*atrophy, Parkinson's disease, and pure autonomic failure*

## **CAPSULES**

**Adults.** *Initial:* 100 mg three times daily: upon arising in the morning, at midday, and in the late afternoon at least 3 hr before bedtime. Dosage then titrated to symptomatic response in increments of 100 mg three times daily every 24 to 48 hr to maximum dosage. *Maximum:* 600 mg three times daily.

## **Mechanism of Action**

Produces peripheral arterial and venous vasoconstriction, which increases blood pressure.

## **Contraindications**

Hypersensitivity to droxidopa or its components

## **Interactions**

### **DRUGS**

*dopa-decarboxylase inhibitors:* Possibly altered plasma droxidopa levels

*ephedrine, midodrine, norepinephrine, triptans and other drugs that increase blood pressure:* Increased risk of supine hypertension

*nonselective MAO inhibitors such as rasagiline, selegiline; linezolid:* Possibly increased blood pressure

## **Adverse Reactions**

**CNS:** Agitation, confusion, **CVA**, delirium, dizziness, fatigue, fever, hallucination, headache, memory disorder, **neuroleptic malignant syndrome-like complex**, psychosis, syncope

**CV:** Chest pain, **exacerbation of arrhythmias**, **congestive heart failure**, **ischemic heart disease**, hypertension, supine hypertension

**EENT:** Blurred vision

**GI:** Abdominal pain, diarrhea, nausea, **pancreatitis**, vomiting

**GU:** UTI

**RESP:** **Bronchospasm**

**SKIN:** Rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, falls

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding during drug therapy.

## Nursing Considerations

- Check supine blood pressure prior to initiating droxidopa and after increasing the dose to determine effectiveness and detect hypertension.

**WARNING** Elevate head of patient's bed when patient is resting or sleeping to minimize effects of supine hypertension, which droxidopa can cause or exacerbate. Monitor blood pressure in both the supine position and head-elevated sleeping position. Notify prescriber if supine hypertension occurs and expect dosage to be reduced or drug discontinued, because it can increase the risk of cardiovascular events, especially stroke.

- Know that, although rare, droxidopa may cause a symptom complex resembling neuroleptic malignant syndrome (NMS). Observe patients carefully when dosage is changed or when concomitant levodopa is reduced abruptly or discontinued, especially if patient is receiving neuroleptics. Monitor patient for signs and symptoms such as altered consciousness, fever, hyperthermia, involuntary movements, mental status changes, and muscle rigidity. Notify prescriber immediately; an early diagnosis is important because NMS can be life-threatening.

**WARNING** Monitor patient for hypersensitivity reactions that may include anaphylaxis, angioedema, bronchospasm, rash, and urticaria. If present, withhold droxidopa, notify prescriber, provide emergency supportive care as ordered, and expect drug to be discontinued.

- Be aware that droxidopa contains FD&C Yellow No. 5 (tartrazine), which may cause an allergic-type reaction such as bronchial asthma. Risk is higher in patients who also have an aspirin hypersensitivity.

## **PATIENT TEACHING**

- Tell patient to take droxidopa three times a day: upon arising in the morning, at midday, and in the late afternoon at least 3 hours prior to bedtime to reduce the potential for supine hypotension during sleep.

- Instruct patient to swallow capsules whole. Advise her that if a dose is missed to wait and take the next scheduled dose. Tell her doses should never be doubled to make up for a missed dose.
- Advise patient to elevate the head of her bed when resting or sleeping to minimize effects of supine hypertension.
- Tell patient to inform prescriber of all new medications, including over-the-counter preparations, prior to taking them.

**WARNING** Instruct patient to stop taking droxidopa and seek emergency medical attention if signs and symptoms of an allergic reaction occur, such as difficulty breathing, hives, rash, or swelling.

- Inform mothers that they should not breastfeed while taking droxidopa.

## dulaglutide

### Trulicity

## Class and Category

*Pharmacologic class:* Glucagon-like peptide-1 receptor agonist

*Therapeutic class:* Antidiabetic

## Indications and Dosages

- *Adjunct to diet and exercise to improve glycemic control in patients with type 2 diabetes mellitus*

## SUBCUTANEOUS INJECTION

**Adults.** 0.75 mg once weekly, increased to 1.5 mg once weekly, as needed. *Maximum:* 1.5 mg once weekly.

## Mechanism of Action

Activates the GLP-1 receptor to increase intracellular cyclic AMP (cAMP) in beta cells, causing a glucose-dependent insulin release. Insulin then lowers blood glucose levels. Dulaglutide also decreases glucagon secretion and slows gastric emptying to further decrease blood glucose levels.

## Contraindications

Hypersensitivity to dulaglutide or its components, personal or family history of medullary thyroid carcinoma or multiple endocrine neoplasia syndrome type 2, preexisting severe gastrointestinal disease

## Interactions

### DRUGS

*insulin, insulin secretagogues:* Increased risk of hypoglycemia

*orally administered drugs:* Possibly decreased absorption of the orally administered drugs

## Adverse Reactions

**CNS:** Asthenia, fatigue, malaise

**CV:** First-degree AV block, sinus tachycardia

**ENDO:** **Hypoglycemia**

**GI:** Abdominal distention or pain, constipation, diarrhea, dyspepsia, elevated liver enzymes, flatulence,

gastroesophageal reflux disease, nausea, **pancreatitis**, vomiting

**GU: Acute renal failure**, elevated creatinine level, **worsening chronic renal failure**

**SKIN:** Pruritus, rash, urticaria

**Other: Angioedema**, injection-site reactions such as erythema and rash

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that dulaglutide should not be used as first-line therapy for patients who have inadequately controlled their blood glucose levels on diet and exercise alone.
- Use caution when beginning dulaglutide therapy or titrating dose in patients with renal impairment. Monitor renal function in these patients if they experience severe adverse gastrointestinal reactions. Also use cautiously in patients with hepatic impairment because the effect of dulaglutide therapy on the liver is unknown.
- Be aware that dulaglutide may potentially be linked to the development of thyroid C-cell tumors. While elevated serum calcitonin is a biological marker, its value in routine monitoring is unclear. If an elevated serum calcitonin level is found at any time during therapy, expect patient to be referred to an endocrinologist for further evaluation.

- Monitor patient for signs and symptoms of pancreatitis, such as persistent severe abdominal pain, sometimes radiating to the back, which may or may not be accompanied by vomiting. If confirmed, expect dulaglutide to be discontinued.
- Monitor patient also receiving insulin or insulin secretagogue therapy concomitantly for hypoglycemia. The dosage of insulin or insulin secretagogue may need to be lowered to reduce the risk of hypoglycemia. If hypoglycemia occurs, treat it according to policy and notify prescriber.
- Monitor patient for signs of hypersensitivity such as pruritus, rash, or urticaria. If present, withhold drug, notify prescriber, and expect drug to be discontinued.
- Monitor patient for signs of diarrhea, dehydration, nausea or vomiting, which may suggest renal impairment. If present, notify prescriber because the frequency of these gastrointestinal symptoms may increase as renal function declines.

## PATIENT TEACHING

- Inform patient that drug may be administered at any time of day without regard to meals but that it should be administered on the same day each week. However, if the day of the week needs to be changed, that change may be made, as long as the last dose was administered 4 or more days earlier.
- Instruct patient that if a dose is missed it should be administered when remembered if there are at least 3 days (72 hours) until the next scheduled dose. If it is within 1 to 2 days of his next regularly scheduled dose, he should administer at the regularly scheduled time.
- Teach patient to administer the injection into the abdomen, thigh, or upper arm region. Instruct patient that if the same body region is being used each week, the sites of injection should be rotated within that region. Tell patient how to safely dispose of the used pen and needle.

**WARNING** Instruct patient to stop taking dulaglutide and seek immediate emergency care if any of the following allergic reactions occurs: difficulty breathing or swallowing; dizziness, fainting; feeling itching; rapid heartbeat; severe rash; or swelling of face, lips, tongue, or throat.

- Teach female patients to alert prescriber if pregnancy occurs or is suspected.
- Ensure that patient has been informed of the potential risk for developing thyroid tumors before starting dulaglutide therapy. Tell patient to report any symptoms of thyroid tumors such as a mass in the neck, difficulty swallowing or breathing, or persistent hoarseness.
- Instruct patient on the signs and symptoms of hypoglycemia and how to treat it. Inform patient who is also receiving an insulin secretagogue or insulin that the risk of hypoglycemia is greater. Tell patient to notify prescriber if hypoglycemia occurs frequently or is severe.
- Tell patient to notify prescriber if any orally administered drugs appear to be losing their effectiveness, as dulaglutide causes a delay of gastric emptying and has the potential to affect the absorption of drugs taken by mouth. Also tell prescriber about any new prescribed medication or over-the-counter preparation before using.

## **duloxetine hydrochloride**

**Cymbalta**

### **Class and Category**

*Pharmacologic class:* Selective serotonin and norepinephrine reuptake inhibitor

*Therapeutic:* Antidepressant, neuropathic and musculoskeletal pain reliever

### **Indications and Dosages**

➤ *To treat major depressive disorder*

**E.R. CAPSULES**

**Adults.** *Initial:* 20 mg twice daily increased, as needed. Alternatively, 60 mg once daily or 30 mg twice daily. *Maintenance:* 60 mg/day. Maximum: 120 mg/day.

- *To relieve neuropathic pain associated with diabetic peripheral neuropathy*

## **E.R. CAPSULES**

**Adults.** 60 mg daily.

- *To treat generalized anxiety disorder*

## **E.R. CAPSULES**

**Adults.** *Initial:* 30 or 60 mg once daily, increased in 30-mg increments weekly, as needed. *Maximum:* 120 mg once daily.

**Children age 7 to 17 years of age.** *Initial:* 30 mg once daily for 2 wk, then increased in 30-mg increments weekly, as needed. *Maximum:* 120 mg daily.

***DOSAGE ADJUSTMENT*** For elderly patients, dosage initiated at 30 mg once daily for 2 weeks, before dosage increased to 60 mg once daily. Further increases in dosage made in 30-mg increments weekly, as needed, to maximum dosage of 120 mg once daily.

- *To treat fibromyalgia; to treat chronic musculoskeletal pain*

## **E.R. CAPSULES**

**Adults.** *Initial:* 30 mg daily for 1 wk; then increased to 60 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	6 hr	Unknown

## Mechanism of Action

Inhibits dopamine, neuronal serotonin, and norepinephrine reuptake to potentiate noradrenergic and serotonergic activity in the CNS. These activities may elevate mood and inhibit pain signals stemming from peripheral nerves adversely affected by chronically elevated serum glucose level.

## Contraindications

Chronic liver disease including cirrhosis, hypersensitivity to duloxetine or its components severe renal impairment (glomerular filtration rate less than 30 ml/min), use of linezolid or intravenous methylene blue, use of MAO inhibitors within 5 days of stopping duloxetine or within 14 days of stopping MAO inhibitors

## Interactions

### DRUGS

*amphetamines, buspirone, fentanyl, intravenous methylene blue, lithium, linezolid, MAO inhibitors, selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors, St. John's Wort, tramadol, tricyclic antidepressants, triptans, tryptophan:* Increased risk of serotonin syndrome  
*aspirin, NSAIDs, warfarin:* Possibly increased risk of bleeding  
*cimetidine, fluoxetine, fluvoxamine, paroxetine, quinidine, quinolones:* Increased blood duloxetine level  
*CNS drugs:* Increased effect of duloxetine  
*CYP1A2, CYP2D6 inhibitors:* Altered duloxetine metabolism  
drugs that raise gastrointestinal pH: Possibly early release

of duloxetine

*phenothiazines, tricyclic antidepressants (such as amitriptyline, imipramine, nortriptyline), type 1C antiarrhythmics (such as flecainide, propafenone):* Increased plasma levels of these drugs with possible increase in adverse reactions

*thioridazine:* Increased plasma thioridazine levels increasing risk of serious ventricular arrhythmias and sudden death

## ACTIVITIES

*alcohol use:* Increased risk of hepatotoxicity

## Adverse Reactions

**CNS:** Abnormal dreams, aggression, agitation, anger, anxiety, asthenia, chills, dizziness, extrapyramidal disorder, fatigue, fever, hallucinations, headache, insomnia, migraine, nervousness, **neuroleptic malignant syndrome**, parasthesia, restless legs syndrome, **seizures**, **serotonin syndrome**, somnolence, **suicidal ideation**, syncope, tremor, vertigo

**CV:** Hypertension, **hypertensive crisis**, **MI**, orthostatic hypotension, palpitations, paresthesia, peripheral edema or coldness, **supraventricular arrhythmia**, tachycardia, **Takotsubo cardiomyopathy**

**EENT:** Acute-angle glaucoma, blurred vision, dry mouth, glaucoma, nasopharyngitis, pharyngitis, taste alteration, tinnitus

**ENDO:** Galactorrhea, hot flashes, hyperglycemia, hyperprolactinemia

**GI:** **Acute pancreatitis**, abdominal pain, anorexia, cholestatic jaundice, colitis, constipation, diarrhea, elevated liver enzymes, flatulence, **hepatitis**, **hepatotoxicity**, indigestion, jaundice, nausea, upper abdominal pain, vomiting

**GU:** Abnormal orgasm; decreased libido; erectile or ejaculatory dysfunction; **gynecological bleeding**; urinary frequency, hesitancy, or retention; UTI

**HEME:** **Bleeding episodes** (may range from mild to **life-threatening**), **leukopenia**, **thrombocytopenia**

**MS:** Arthralgia, back pain, extremity pain, muscle cramp or spasm, myalgia

**RESP:** Cough, upper respiratory tract infection

**SKIN:** Cutaneous vasculitis, diaphoresis, **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **hyponatremia**, weight loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-814-6975 or [www.cymbaltapregnancyregistry.com](http://www.cymbaltapregnancyregistry.com).
- It is not known if drug causes fetal harm. However, be aware that neonates exposed to the drug during pregnancy may develop serious and life-threatening adverse reactions, which can arise immediately following birth. These adverse reactions may require prolonged hospitalization, respiratory support, and tube feeding.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

- Use of drug in the month before delivery may increase risk of postpartum hemorrhage.

## **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, infant should be monitored for drowsiness, poor feeding, and poor weight gain.

## **Nursing Considerations**

- Know that duloxetine should not be given to patients with severe renal impairment or end-stage renal disease that requires hemodialysis because blood drug levels increase significantly in these patients. Also know that duloxetine should be avoided in patients with hepatic insufficiency or who use alcohol excessively because drug is metabolized by the liver.
- Use duloxetine cautiously in patients with delayed gastric emptying because drug's enteric coating resists dissolution until it reaches an area where pH exceeds 5.5.
- Give duloxetine cautiously to patients with a history of mania, which it may activate. Also give cautiously to patients with a seizure disorder because drug effects aren't known in these patients.
- Obtain patient's baseline blood pressure before duloxetine therapy starts, and assess it periodically thereafter for changes. If orthostatic hypotension occurs during therapy, notify prescriber and anticipate that drug may need to be discontinued.
- Monitor patient's serum sodium level, as ordered, especially if patient is elderly, is taking a diuretic, or has volume depletion, because drug may lower serum sodium level.
- Monitor patient's hepatic function, as ordered, because drug may increase the risk of hepatotoxicity. Expect to discontinue duloxetine, as ordered, if patient develops jaundice or other serious liver dysfunction manifestation.
- Watch closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.
- Avoid stopping duloxetine therapy abruptly, if possible, because withdrawal symptoms such as anxiety, diarrhea, dizziness, fatigue,

headache, hyperhidrosis, insomnia, irritability, nausea, nightmares, paresthesia, vertigo, and vomiting, may occur. Taper dosage gradually, as ordered.

**WARNING** Monitor patient for serotonin syndrome, characterized by agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. In its most severe form, serotonin syndrome can resemble neuroleptic malignant syndrome, which includes autonomic instability with possible fluctuations in vital signs, high fever, mental status changes, and muscle rigidity.

**WARNING** Know that treatment with linezolid or I.V. methylene blue is not recommended while patient is taking duloxetine because of increased risk of serotonin syndrome. However, if prescriber feels benefits outweigh the risks, expect duloxetine to be discontinued promptly if serotonin syndrome occurs. Monitor patient closely for serotonin syndrome for 5 days or until 24 hours after the last dose of linezolid or I.V. methylene blue, whichever comes first. Know that therapy with duloxetine may be resumed 24 hours after the last dose of linezolid or I.V. methylene blue.

## **PATIENT TEACHING**

- Tell patient to take capsule whole and not to chew it, crush it, or sprinkle contents on food or liquids, because doing so alters enteric coating and may affect drug absorption.
- Inform patient that full effect of duloxetine may take weeks to occur; emphasize the importance of continuing to take the drug as directed.
- Caution patient against excessive alcohol consumption while taking duloxetine because it may increase risk of hepatic dysfunction. Also tell him to report a yellowing of skin immediately, as drug may have to be discontinued.

- Advise patient not to stop duloxetine abruptly because adverse reactions may occur. Explain that drug will be stopped gradually.
- Instruct patient to notify prescriber if any serious or troublesome adverse effects develop, especially if they are persistent, severe, or unusual.
- Advise patient that drug may increase risk of bleeding. Tell patient to notify prescriber if mild bleeding occurs or seek immediate medical attention if severe. Tell patient to consult prescriber before taking aspirin or NSAIDs.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute-angle glaucoma. Encourage him to have an eye exam before starting therapy to see if he is at risk.
- Instruct patient to rise from a lying or sitting position slowly to minimize drug's effect on lowering blood pressure, which may possibly lead to falls or cause patient to faint.
- Urge caregivers to watch closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes.
- Instruct female patients of childbearing age to notify prescriber if they are, could be, or wish to become pregnant; duloxetine therapy may cause adverse reactions in neonates exposed to it during the third trimester. If patient becomes pregnant while taking duloxetine, urge her to enroll in the Pregnancy Registry by calling 1-866-814-6975 or visiting [www.cymbaltapregnancyregistry.com](http://www.cymbaltapregnancyregistry.com).
- Tell patient to stop taking duloxetine and notify prescriber immediately at the first sign of blisters, mucosal erosions, peeling rash, or any other sign of hypersensitivity, as drug will need to be discontinued.
- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute-angle glaucoma. Encourage him to have an eye exam before starting therapy to see if he is at risk.
- Instruct patient with diabetes to monitor his blood glucose levels more closely, as duloxetine therapy can alter control.
- Tell patient to notify prescriber of any new medication, including over-the-counter preparations, before using.

# dutasteride

**Avodart**

## Class and Category

*Pharmacologic class:* 5-alpha-reductase enzyme inhibitor

*Therapeutic class:* Benign prostatic hyperplasia agent

## Indications and Dosages

- *To treat symptomatic benign prostatic hyperplasia (BPH); as adjunct with tamsulosin therapy to treat symptomatic BPH*

## CAPSULES

**Adult men.** 0.5 mg daily.

## Contraindications

Children; hypersensitivity to dutasteride other 5-alpha reductase inhibitors or their components; pregnancy; women of childbearing age

## Mechanism of Action

Dutasteride reduces prostate gland enlargement by inhibiting conversion of testosterone to its active metabolite, 5-alpha dihydrotestosterone (DHT). DHT is the main hormone that stimulates prostate cells to

grow. As men age, they may become more sensitive to DHT, resulting in excessive growth of prostatic cells and enlargement of the prostate. This condition, benign prostatic hyperplasia, may cause nocturia, urinary hesitancy, and urinary urgency.

Two forms of the intracellular enzyme 5-alpha-reductase (5α-R types 1 and 2) in liver, prostate, and skin, convert testosterone to DHT, as shown below left. Dutasteride, a dual 5α-R inhibitor, deactivates both forms. When 5α-R is inhibited by dutasteride, production of DHT is suppressed, as shown below

right. With less circulating DHT, the prostate gland shrinks and symptoms improve.

Description

## Interactions

### DRUGS

*CYP3A4* inhibitors such as cimetidine, ciprofloxacin, diltiazem, ketoconazole, ritonavir, verapamil: Increased dutasteride exposure and enhanced effects including increased risk of adverse reactions

# Adverse Reactions

**CNS:** Depression, dizziness

**ENDO:** Gynecomastia, increased serum testosterone and thyroid-stimulating hormone levels, **male breast cancer**

**GU:** Decreased ejaculatory volume, decreased libido, **high-grade prostate cancer**, impotence, testicular pain and swelling

**SKIN:** Localized edema, pruritus, rash, serious skin reactions, urticaria

**Other:** **Angioedema**

# Childbearing Considerations

## PREGNANCY

- Drug may cause fetal harm such as abnormalities in the genitalia of male fetuses.
- Drug is contraindicated in women who are or who may become pregnant during drug therapy.

## LACTATION

- It is not known if drug is present in breast milk.
- Drug is contraindicated in women of childbearing potential

## REPRODUCTION

- Be aware that drug's effect on fertility of male patients is unknown. However, there is some evidence to suggest drug may decrease sperm count.

# Nursing Considerations

**WARNING** Be aware that dutasteride is absorbed through the skin, so female healthcare workers should not handle dutasteride capsules, especially if of childbearing age or pregnant.

- Know that patient should be evaluated for other urologic conditions, including prostate cancer, before dutasteride therapy starts because dutasteride therapy increases risk of patient developing high-grade prostate cancer.
- Expect patient to undergo a digital rectal examination of the prostate before and periodically during dutasteride therapy.
- Anticipate need to obtain a new baseline prostate-specific antigen (PSA) value after 3 to 6 months of dutasteride treatment because drug can decrease PSA concentration by 40% to 50%. Dutasteride also can decrease serum PSA level in the presence of prostate cancer. Any PSA reading in a patient receiving dutasteride should be doubled for comparison with normal values in untreated men. If value still falls within the normal range for men not taking a 5-alpha-reductase inhibitor, further evaluation should still be done to rule out prostate cancer.

## **PATIENT TEACHING**

**WARNING** Urge patient and female partners to use reliable contraceptive method during dutasteride therapy because semen of men who take drug can harm male fetuses. Caution women and children against handling capsules.

- Advise patient to inform prescriber if he has liver disease.
- Explain how to take drug properly, and advise patient to follow instructions that accompany drug. Instruct him to swallow capsule whole and to notify pharmacist if capsules are cracked or leaking.
- Inform patient that drug may decrease ejaculatory volume and libido and may cause impotence.
- Instruct patient to postpone blood donations for 6 months after final dose to avoid transmitting dutasteride to a pregnant woman during a blood transfusion.
- Urge patient to have periodic follow-up appointments.

## E F

**edoxaban**

**Savaysa**

### **Class and Category**

*Pharmacologic class:* Factor Xa inhibitor

*Therapeutic class:* Anticoagulant

### **Indications and Dosages**

- *To reduce risk of stroke and systemic embolism in nonvalvular atrial fibrillation*

#### **TABLETS**

**Adults.** 60 mg once daily.

***DOSAGE ADJUSTMENT*** For patients with impaired renal failure (creatinine clearance between 15 and 50 ml/min), dosage reduced to 30 mg once daily.

- *To treat deep vein thrombosis and pulmonary embolism*

#### **TABLETS**

**Adults.** 60 mg once daily following 5 to 10 days of initial therapy with a parenteral anticoagulant.

**DOSAGE ADJUSTMENT** For patients with impaired renal failure (creatinine clearance between 15 and 50 ml/min), patients who weigh less than or equal to 60 kg (132 lb), or patients who are taking selected concomitant P-gp inhibitors (quinidine, verapamil, or short term concomitant administration of azithromycin, clarithromycin, erythromycin, oral itraconazole or oral ketoconazole), dosage reduced to 30 mg once daily.

## Mechanism of Action

Inhibits free FXa and prothrombinase activity and inhibits thrombin-induced platelet aggregation. By inhibiting FXa in the coagulation cascade, thrombin generation and formation is reduced.

## Contraindications

Active pathological bleeding, hypersensitivity to edoxaban or its components

## Interactions

### DRUGS

*anticoagulants, antiplatelets, aspirin or aspirin-containing products, NSAIDs (long-term use), selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors, thrombolytics:* Increased risk of bleeding

*rifampin:* Decreased effectiveness of edoxaban

*quinidine, verapamil, or short term concomitant administration of azithromycin, clarithromycin, erythromycin, oral itraconazole or oral ketoconazole:* Increased blood level with increased risk of bleeding in

patients being treated for deep venous thrombosis or pulmonary embolism

## Adverse Reactions

**CNS:** Intracranial bleeding

**EENT:** Epistaxis, intraocular bleeding

**GI:** Elevated liver enzymes, GI bleeding

**GU:** Hematuria, vaginal bleeding

**HEME:** Anemia, bleeding, thrombocytopenia

**RESP:** Interstitial lung disease

**SKIN:** Rash, urticaria

**Other:** Angioedema, hypersensitivity reactions

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm because use of drug may increase risk of bleeding in the fetus and neonate.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Drug withheld, if possible, and replaced with a shorter acting anticoagulant as delivery approaches because of increased risk of bleeding.

### LACTATION

- It is not known if drug is present in breast milk.

- Breastfeeding is not recommended during drug therapy.

## Nursing Considerations

- Know that edoxaban should not be administered to a patient who has a creatinine clearance greater than 95 ml/min because of an increased risk ischemic stroke.
- Keep in mind that edoxaban is not recommended for use in patients with a mechanical heart valve or who have moderate to severe mitral stenosis because the effects of edoxaban in these patients are unknown.
- Know that for a patient unable to swallow tablets, tablet should be crushed and mixed with 2 to 3 ounces of water and immediately administered by mouth or through a gastric tube. Crushed tablet can also be mixed with applesauce and immediately given by mouth.
- Be aware that edoxaban should be withheld for at least 24 hours before invasive or surgical procedures are performed to reduce the risk of bleeding. If it is not possible to delay the procedure, monitor patient closely for bleeding. If edoxaban was withheld, know that it may be restarted after the invasive or surgical procedure as soon as the patient has achieved adequate hemostasis. Be prepared to administer a parenteral anticoagulant if oral medication cannot be initially taken and then when oral medication can be taken, the patient may be switched to edoxaban.
- Know that when a patient is being transitioned to edoxaban from warfarin or other vitamin K antagonist, warfarin should be discontinued and edoxaban started when the INR is 2.5 or less; transitioned from oral anticoagulants other than warfarin or other vitamin K antagonists, the current oral anticoagulant should be discontinued and edoxaban started at the time of the next scheduled dose of the other oral anticoagulant; transitioned from low-molecular-weight heparin, the low-molecular-weight heparin should be discontinued and edoxaban started at the time of the next scheduled administration of the low-molecular-weight heparin; or transitioned from unfractionated heparin, the unfractionated heparin infusion should be discontinued and edoxaban started 4 hours later.
- Be aware that when a patient is being transitioned from edoxaban (60 mg dose) to warfarin, the dose of edoxaban should be reduced to 30 mg and warfarin begun concomitantly. When a patient is being transitioned from edoxaban (30 mg dose) to warfarin, the dose of edoxaban should be reduced to 15 mg and warfarin begun concomitantly. When a stable INR of 2 or greater is achieved in either situation, edoxaban should be discontinued. Know that a second method of transitioning a patient from

edoxaban to warfarin may be used. In this method, edoxaban should be discontinued and a parenteral anticoagulant and warfarin administered, as ordered, at the same time of the next scheduled edoxaban dose. Once a stable INR of 2 or greater is achieved, the parenteral anticoagulant should be discontinued and warfarin therapy continued. Be aware that when a patient is being transitioned from edoxaban to a non-vitamin K dependent oral anticoagulant, edoxaban should be discontinued and the other oral anticoagulant started at the time of the next dose of edoxaban. Know that when a patient is being transitioned from edoxaban to a parenteral anticoagulant, edoxaban should be discontinued and the parenteral anticoagulant should be started at the time of the next dose of edoxaban.

**WARNING** Monitor patient receiving edoxaban and epidural or spinal anesthesia or spinal puncture because spinal hematomas can occur, causing long-term or permanent paralysis. Watch for evidence of neurologic impairment, such as changes in motor or sensory function. If present, notify prescriber immediately; patient needs urgent care to minimize effect of hematoma. Use of indwelling epidural catheters; concurrent use of other drugs that affect hemostasis such as nonsteroidal anti-inflammatory drugs, platelet inhibitors, and other anticoagulants; a history of traumatic or repeated epidural or spinal punctures; or a history of spinal deformity or spinal surgery increases the risk of epidural or spinal hematoma in patients receiving edoxaban.

- Expect to receive another anticoagulant, as ordered, if edoxaban must be discontinued for reasons other than the presence of active bleeding or therapy is no longer needed. This is because premature discontinuation of edoxaban increases the risk of ischemic events.
- Monitor patient closely for bleeding. If present, notify prescriber immediately because there is no antidote to reverse the anticoagulation effects of edoxaban, which may last for up to 24 hours after the last dose. Know that patients who take other drugs that affect hemostasis, such as aspirin and other antiplatelet agents, chronic use of nonsteroidal anti-inflammatory drugs, fibrinolytic therapy, or other antithrombotic drugs, are at increased risk for bleeding.

- Know that the use of anticoagulants, including edoxaban, may increase the risk of bleeding in the fetus and neonate. Monitor neonate for bleeding if mother was taking edoxaban prior to birth.

## **PATIENT TEACHING**

- Tell patient that if she misses a dose of edoxaban, she should take the dose as soon as possible on the same day and resume the dosing for the next day at the normal time. However, if she forgets the dose until the next day, she should not double the dose to make up for the missed dose.
- Inform patient unable to swallow tablets that edoxaban may be crushed and mixed with 2 to 3 ounces of water or mixed in applesauce and immediately taken by mouth.
- Instruct patient on bleeding precautions. If bleeding occurs, tell her to report any unusual bleeding immediately to the prescriber.
- Caution patient not to stop taking edoxaban without talking to her prescriber first.
- Tell patient to alert all healthcare providers and dentists that she is taking edoxaban and to consult the prescriber before taking any new drugs, including OTC drugs.
- Stress importance for females of child-bearing age to notify prescriber if pregnancy occurs or is suspected. This is because anticoagulants, including edoxaban, may increase the risk of bleeding in the fetus and neonate. Tell mother who took edoxaban during late pregnancy to watch neonate for bleeding.
- Advise mothers that breastfeeding is not recommended during edoxaban therapy because of the potential risk of serious adverse reactions.

**WARNING** Alert patient who is having neuraxial anesthesia or spinal puncture to immediately report signs and symptoms suggestive of epidural or spinal hematomas such as back pain, muscle weakness, numbness (especially in the lower limbs), stool or urine incontinence, and tingling.

# efavirenz

## Sustiva

### Class and Category

*Pharmacologic class:* Non-nucleoside reverse transcriptase inhibitor

*Therapeutic class:* Antiretroviral

### Indications and Dosages

- *As adjunct to treat human immunodeficiency virus type 1 (HIV-1) in combination with other antiretroviral agents*

#### CAPSULES, TABLETS

**Adults and children weighing 40 kg (88 lb) or more.** 600 mg once daily at bedtime on an empty stomach.

**Children age 3 months and older and weighing 32.5 kg (71.5 lb) to less than 40 kg (88 lb).** 400 mg once daily at bedtime on an empty stomach.

**Children age 3 months and older and weighing 25 kg (55 lb) to less than 32.5 kg (71.5 lb).** 350 mg once daily at bedtime on an empty stomach.

**Children age 3 months and older and weighing 20 kg (44 lb) to less than 25 kg (55 lb).** 300 mg once daily at bedtime on an empty stomach.

**Children age 3 months and older and weighing 15 kg (33 lb) to less than 20 kg (44 lb).** 250 mg once daily at bedtime on an empty stomach.

**Children age 3 months and older and weighing 7.5 kg (16.5 lb) to less than 15 kg (33 lb).** 200 mg once daily at bedtime on an empty stomach.

**Children age 3 months and older and weighing 5 kg (11 lb) to less than 7.5 kg (16.5 lb).** 150 mg once daily at bedtime on an empty stomach.

**Children age 3 months and older and weighing 3.5 kg (7.7 lb) to less than 5 kg (11 lb).** 100 mg once daily at bedtime on an empty stomach.

***DOSAGE ADJUSTMENT*** For adult patients weighing 50 kg (110 lb) and also receiving rifampin, dosage increased to 800 mg once daily. For adult patients receiving voriconazole concurrently, dosage decreased to 300 mg once daily.

## **Mechanism of Action**

Inhibits HIV integrase by binding to the integrase active site and blocking the strand transfer step of retroviral DNA integration, which is needed for the HIV replication cycle.

## **Contraindications**

Concurrent therapy with elbasvir and grazoprevir, hypersensitivity to efavirenz or its components

## **Interactions**

### **DRUGS**

*artemether, atazanavir, atorvastatin, atovaquone, boceprevir, bupropion, clarithromycin, cyclosporine,*

*dihydroartemisinin, diltiazem, ethinyl estradiol/norgestimate, etonogestrel implant, felodipine, fosamprenavir, hydroxyitraconazole, immunosuppressants, indinavir, ketoconazole, itraconazole, lopinavir, lumefantrine, maraviroc, methadone, nicardipine, nifedipine, posaconazole, pravastatin, proguanil, rifabutin, saquinavir, sertraline, simeprevir, simvastatin, sirolimus, tacrolimus, velpatasvir/sofosbuvir, velpatasvir/sofosbuvir/voxilaprevir, verapamil:* Decreased effectiveness of these drugs

*carbamazepine, phenobarbital, phenytoin:* Decreased plasma levels of both drugs

*CYP3A inducers:* Decreased plasma levels of efavirenz with decreased effectiveness

*elbasvir/grazoprevir, pibrentasvir/glecaprevir:* Possibly loss of virologic response and reduced therapeutic effect

*other nonnucleoside reverse transcriptase inhibitors:* Decreased or increased plasma levels of both drugs without added efficacy

*psychoactive drugs:* Possibly additive central nervous system effects

*QT prolongation drugs such as artemether/lumefantrine, clarithromycin:* Increased risk of Torsade de Pointes

*rifabutin:* Decreased plasma levels of both drugs decreasing effectiveness

*rifampin:* Decreased plasma efavirenz levels with possible decrease in effectiveness

*ritonavir:* Increased plasma levels of both efavirenz and ritonavir, possibly leading to elevated liver enzymes and other adverse reactions

*voriconazole*: Decreased voriconazole level and increased plasma efavirenz

*warfarin*: Decreased or increased warfarin levels, requiring close monitoring of INR and adjustment of warfarin dosage as needed

## **ACTIVITIES**

*alcohol use*: Possibly increased additive central nervous system effects

## **Adverse Reactions**

**CNS**: Abnormal dreams, aggression, agitation, amnesia, anxiety, asthenia, ataxia, catatonia, cerebellar balance and coordination disturbances, confusion, delusions, depersonalization, depression (severe), dizziness, emotional lability, **encephalopathy**, euphoria, fatigue, fever, hallucinations, headache, hypoesthesia, impaired concentration, insomnia, paranoid behavior, manic reactions, nervousness, neuropathy, neurosis, paranoia, paresthesia, psychosis-like behavior, **seizures**, somnolence, stupor, **suicidal ideation**, tremor, vertigo

**CV**: Elevated cholesterol and triglyceride levels, palpitations, **QT prolongation**

**EENT**: Abnormal vision, tinnitus

**ENDO**: Cushingoid appearance, fat redistribution, gynecomastia, hyperglycemia

**GI**: Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, elevated amylase or liver enzymes, **hepatic failure**, **hepatitis**, **hepatotoxicity**, malabsorption, nausea, **pancreatitis**, vomiting

**HEME**: **Neutropenia**

**MS:** Arthralgia, myalgia, myopathy

**RESP:** Dyspnea

**SKIN:** Blisters, **erythema multiforme**, flushing, moist desquamation, photoallergic dermatitis, pruritus, rash, **Stevens-Johnson syndrome**, ulcerations

**Other:** **Allergic reactions**, nonspecific pain, immune reconstitution syndrome

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- Be aware pregnancy testing should be done in women of childbearing age prior to initiation of drug therapy.
- It is not known if drug causes fetal harm. However, there are retrospective reports of neural tube defects in infants whose mothers were exposed to an efavirenz-containing regimen in the first trimester of pregnancy.
- Drug should not be given during the first trimester of pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

### REPRODUCTION

- Effective contraceptive measures should be in place prior to beginning drug therapy as well as throughout therapy and for 12 weeks after drug is discontinued.

- Barrier contraception should always be used in combination with other methods of contraception.
- Know that hormonal methods of contraception that contain progesterone may not be as effective.

## Nursing Considerations

- Be aware that efavirenz should not be used as a single agent in treating HIV infection, because resistant virus emerges quickly when drug is used alone.
- Know that efavirenz therapy is not recommended with the combination drug Atripla, which contains efavirenz, unless needed for dose adjustment when coadministered with rifampin.
- Know that drug should not be used in patients taking other medications with a known risk of torsades de pointes or in patients at higher risk of torsades de pointes, because efavirenz may cause QT prolongation.
- Obtain liver enzymes before therapy begins, as ordered, in patients with marked transaminase elevations, patients treated with other medications associated with liver toxicity, and patients with underlying hepatic disease, including hepatitis B or C infections. Also monitor liver enzymes throughout therapy, as ordered, on all patients, because efavirenz may cause hepatotoxicity. Know that persistent elevations of serum transaminase levels greater than five times the upper limit of the normal range may require efavirenz therapy to be discontinued.
- Obtain cholesterol and triglyceride levels before efavirenz is begun and periodically throughout therapy, because drug may cause an increase in total cholesterol and triglycerides.
- Use efavirenz cautiously in patients with a history of seizures, as drug may increase risk of seizures. Know that if patient is also taking anticonvulsant medications metabolized by the liver, such as phenobarbital or phenytoin, periodic monitoring of plasma levels of these drugs may be required.

**WARNING** Monitor patient for rash. While usually mild to moderate, occurring within the first 2 weeks of therapy, and resolving within a month, a rash rarely may evolve into more serious skin conditions that could become life-threatening and should be reported. Know that it is

recommended that children be given antihistamines and/or corticosteroids before initiating therapy, as a prophylactic measure.

- Monitor patient for serious psychiatric adverse reactions such as aggressive behavior, manic reactions, paranoia, severe depression, or suicidal ideation. Patients at increased risk include patients with drug addiction (injected) or psychiatric history including use of psychiatric drugs.
- Monitor patient for nervous system symptoms that commonly occur with efavirenz use. Be especially watchful for abnormal dreams, dizziness, hallucinations, impaired concentration, insomnia, and somnolence. Be aware that these symptoms usually occur within a day or two of starting therapy and usually resolve in the first 2 to 4 weeks. However, know that late-onset neurotoxicity, including ataxia and encephalopathy, may occur months to years after beginning efavirenz therapy.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including efavirenz. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jirovecii* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.

## PATIENT TEACHING

- Inform patient that efavirenz is not to be taken alone and to follow administration instructions as ordered, noting that drug should be taken on an empty stomach at bedtime.
- Instruct patient or parent that if patient is unable to swallow capsule form, it may be opened and sprinkled on 1 to 2 teaspoonfuls of food such as applesauce, grape jelly, or yogurt. The capsule should be opened carefully so as not to spill any of the contents or disperse drug into the air. To accomplish this, tell patient to hold capsule horizontally over a small container and carefully twist open. If child is unable to consume food, the entire capsule contents may be gently mixed into 2 teaspoons of reconstituted room-temperature infant formula, stirred gently with a small spoon, and then drawn up into a 10-ml oral dosing syringe for administration. After administration, an additional 2 teaspoons of formula should be added to the empty mixing container, stirred, and administered. Caution that the food or formula mixture should be administered within

30 minutes of mixing and no additional food should be consumed for 2 hours after the drug is given.

- Inform patient that efavirenz therapy may cause changes in his body appearance because of fat redistribution. Prepare him for the possibility of developing breast enlargement, central obesity, dorsocervical fat enlargement (buffalo hump), facial wasting, and peripheral wasting.
- Instruct patient to report a rash. Also alert patient that drug may cause nervous system symptoms or psychiatric symptoms. Review these symptoms with patient and urge patient to report to prescriber if present. Advise him also to report any persistent, severe, or unusual signs and symptoms.
- Warn family or caregiver to watch patient closely for evidence of suicidal behavior or thinking.
- Inform patient that neurological adverse reactions such as abnormal dreams, drowsiness, dizziness, impaired concentration, and insomnia may occur in the first weeks of efavirenz therapy but taking drug at bedtime will help and symptoms should diminish with continued therapy. Alert patient to the possibility of late-onset neurotoxicity that may occur months to years after beginning efavirenz therapy. Encourage patient to report any abnormal neurological signs and symptoms regardless of how long efavirenz therapy has been taken.
- Advise patient to contact prescriber before taking any new drugs, including over-the-counter preparations and herbals.
- Caution patient to avoid hazardous activities such as driving until nervous system effects are known and abated.
- Warn women of childbearing age that efavirenz may cause fetal harm when administered during the first trimester of pregnancy. Stress importance of using reliable birth control and tell patient to alert prescriber immediately if pregnancy occurs or is suspected.
- Inform mothers that breastfeeding should not be done while taking efavirenz.

## eletriptan hydrobromide

### **Relpax**

# Class and Category

*Pharmacologic class:* Triptan

*Therapeutic class:* Antimigraine agent

# Indications and Dosages

➤ *To relieve acute migraine attacks with or without aura*

## TABLETS

**Adults.** *Initial:* 20 or 40 mg as a single dose. Repeated in 2 hr, as needed and ordered.

*Maximum:* 40 mg as single dose, 80 mg daily.

# Mechanism of Action

May stimulate 5-HT<sub>1</sub> receptors, causing selective vasoconstriction of dilated and inflamed cranial blood vessels in carotid circulation, which decreases carotid arterial blood flow and relieves acute migraines.

# Contraindications

Bibasilar or hemiplegic migraine, cardiovascular disease (significant), cerebrovascular syndromes (stroke, transient ischemic attack), hepatic impairment (severe), hypersensitivity to eletriptan or components, ischemic bowel disease, ischemic or vasospastic coronary artery disease (CAD), peripheral vascular disease, uncontrolled hypertension, use within 24 hours of another serotonin 5-HT<sub>1</sub> receptor agonist or ergot-type drug, use within 72 hours of a potent CYP3A4 inhibitor (clarithromycin, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, troleandomycin), Wolff-Parkinson-White

syndrome or arrhythmias associated with other cardiac accessory conduction pathway disorders

## Interactions

### DRUGS

*clarithromycin, ketoconazole, itraconazole, nefazodone, nelfinavir, ritonavir, troleandomycin, and other potent CYP3A4 inhibitors:* Increased blood eletriptan level significantly

*ergot-containing drugs, 5-HT<sub>1</sub>receptor agonists:* Possibly additive or prolonged vasoconstrictive effects

*MAO inhibitors, selective serotonin norepinephrine reuptake inhibitors, selective serotonin reuptake inhibitors, tricyclic antidepressants:* Increased risk of serotonin syndrome

## Adverse Reactions

**CNS:** Asthenia, chills, dizziness, headache, hypertonia, hypesthesia, paresthesia, **seizures**, somnolence, tiredness, weakness, vertigo

**CV:** Chest tightness, pain, or pressure; **coronary artery vasospasm**; hypertension, **MI**, or myocardial ischemia (transient); palpitations; **shock**; **ventricular fibrillation or tachycardia**

**EENT:** Dry mouth, pharyngitis, **throat tightness**

**GI:** Abdominal pain, cramps, discomfort, or pressure; dysphagia; indigestion; nausea, vomiting

**MS:** Back pain

**SKIN:** Diaphoresis, flushing

**Other:** Allergic reaction; angioedema; feeling of warmth, pain, or pressure

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Ensure that patients who are at risk for CAD undergo a satisfactory CV evaluation before administering the first dose of eletriptan and that they have a periodic reevaluation of their cardiac status during intermittent long-term therapy.
- Obtain an ECG immediately after first dose of drug in patients who have CV risk factors but who have had a satisfactory CV evaluation because of the drug's potential to cause coronary vasospasm.
- Evaluate patient for CV signs and symptoms after administration of eletriptan and notify prescriber if they occur. Expect drug to be withheld, as ordered, while patient undergoes an extensive CV workup, and discontinued if abnormalities are detected.
- Monitor patient's blood pressure during therapy because of drug's potential to increase blood pressure.

### PATIENT TEACHING

- Advise patient to take eletriptan as soon as possible after onset of migraine symptoms.
- Urge patient to contact prescriber and avoid taking drug if headache symptoms aren't typical.
- Advise against exceeding prescribed dose.
- Instruct patient to seek emergency care for chest, jaw, or neck tightness after taking drug because these may indicate adverse CV reactions; subsequent doses may require ECG monitoring.
- Urge patient to report palpitations.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Advise yearly ophthalmic examinations during prolonged eletriptan therapy.
- Instruct patient to inform prescriber of all drugs he's taking, including OTC products and herbal remedies.

## eltrombopag olamine

### Promacta

## Class and Category

*Pharmacologic class:* Thrombopoietin receptor agonist

*Therapeutic class:* Thrombopoietin agonist

## Indications and Dosages

- *To treat thrombocytopenia in patients with chronic immune (idiopathic) thrombocytopenic purpura and who have had an insufficient response to corticosteroids, immunoglobulins, or splenectomy*

## ORAL SUSPENSION, TABLETS

**Adults and children ages 6 yr and older.** *Initial:* 50 mg daily, increased as needed to maintain a platelet count of  $50 \times 10^9/\text{L}$ . *Maximum:* 75 mg daily.

**Children ages 1 to 5.** *Initial:* 25 mg once daily, increased as needed to maintain a platelet count of  $50 \times 10^9/\text{L}$ .

***DOSAGE ADJUSTMENT*** For adult and pediatric patients 6 years and older of Asian ancestry or patients with moderate to severe hepatic impairment, starting dose of 25 mg daily. For patients of Asian ancestry who also have hepatic impairment, starting dose of 12.5 mg daily. For patients with a platelet count less than  $50 \times 10^9/\text{L}$  following at least 2 weeks of therapy, dosage increased by 25 mg daily to maximum of 75 mg/day unless patient started therapy at 12.5 mg daily, then dosage increased to 25 mg daily before increasing the dose amount by 25 mg, as needed. For patients with a platelet count equal to or greater than  $200 \times 10^9/\text{L}$  but equal to or less than  $400 \times 10^9/\text{L}$ , dosage decreased by 25 mg daily for at least 2 weeks before further dosage adjustment made. For patient with a platelet count greater than  $400 \times 10^9/\text{L}$ , drug should be withheld until platelet count is less than  $150 \times 10^9/\text{L}$  and then restarted at a daily dose reduced by 25 mg, unless patient had been taking 25 mg daily, then dosage restarted at 12.5 mg daily.

- *To treat thrombocytopenia in patients with chronic hepatitis C infection to allow the initiation and maintenance of interferon-based therapy*

## TABLETS

**Adults.** *Initial:* 25 mg daily, increased in increments of 25 mg daily every 2 wk, as needed, to achieve the target

platelet count required to initiate antiviral therapy.

*Maximum:* 100 mg daily.

**DOSAGE ADJUSTMENT** For patients with a platelet count less than  $50 \times 10^9/\text{L}$  following at least 2 weeks of therapy, dosage increased by 25 mg daily to maximum of 100 mg/day. For patients with a platelet count equal to or greater than  $200 \times 10^9/\text{L}$  but equal to or less than  $400 \times 10^9/\text{L}$ , dosage decreased by 25 mg for at least 2 weeks before further dosage adjustment made. For patient with a platelet count greater than  $400 \times 10^9/\text{L}$ , drug should be withheld until platelet count is less than  $150 \times 10^9/\text{L}$  and then restarted at a daily dose reduced by 25 mg, unless patient had been taking 25 mg daily, then dosage restarted at 12.5 mg daily. For patient receiving antiviral therapy, dosage adjusted, as needed, to avoid dose reductions of peginterferon.

➤ *As adjunct with immunosuppressive therapy for first-line treatment of severe aplastic anemia*

## ORAL SUSPENSION, TABLETS

**Adults and children 12 years and over.** *Initial:* 150 mg once daily for 6 months.

**Children age 6 to 11 years.** *Initial:* 75 mg once daily for 6 months.

**Children age 2 to 5 years.** *Initial:* 2.5 mg/kg once daily for 6 months.

**DOSAGE ADJUSTMENT** For patients of Asian ancestry or patients with hepatic impairment, initial dosage decreased by 50%. For patients with a platelet count greater than  $400 \times 10^9/\text{L}$ , drug withheld for 1 week. Once platelet count is less than  $200 \times 10^9/\text{L}$ , drug restarted at a daily dosage reduced by 25 mg for adults and 12.5 mg for children under age 12. For patients with a platelet count greater

than  $200 \times 10^9$  but equal to or less than  $400 \times 10^9$ , daily adult dose decreased by 25 mg every 2 weeks to lowest dose that maintains platelet count equal to or greater than  $50 \times 10^9/L$ , and for children under the age of 12, dosage decreased by 12.5 mg.

- *To treat refractory severe aplastic anemia in patients who have had an insufficient response to immunosuppressive therapy*

## ORAL SUSPENSION, TABLETS

**Adults.** *Initial:* 50 mg once daily, increased as needed in 50-mg increments every 2 wk. *Maximum:* 150 mg daily.

**DOSAGE ADJUSTMENT** For patients of Asian ancestry or patients with any degree of hepatic impairment, initial dosage decreased to 25 mg daily. For patients with a platelet count less than  $50 \times 10^9/L$  following at least 2 weeks of therapy, dosage increased by 50 mg daily to maximum of 150 mg daily. For patients taking 25 mg once daily, dosage increased to 50 mg once daily before dosage increased by 50 mg. For patients with a platelet count equal to or greater than  $200 \times 10^9/L$  but equal to or less than  $400 \times 10^9/L$ , dosage decreased by 50 mg daily for at least 2 weeks before further dosage adjustment made. For patient with a platelet count greater than  $400 \times 10^9/L$ , drug should be withheld for 1 week and until platelet count is less than  $150 \times 10^9/L$  and then drug restarted at a daily dose reduced by 50 mg.

Route	Onset	Peak	Duration
P.O.	Unknown	2–6 hr	Unknown

## Mechanism of Action

Interacts with the transmembrane domain of the thrombopoietin receptor to signal cascades that induce differentiation and proliferation of megakaryocytes from bone marrow progenitor cells. This action increases platelet production, which is abnormally low in patients with thrombocytopenic purpura.

## Contraindications

Hypersensitivity to eltrombopag or its components

## Interactions

### DRUGS

*antacids and mineral supplements containing aluminum, calcium, iron, magnesium, selenium, or zinc:* Decreased eltrombopag absorption

*BCRP substrates (imatinib, irinotecan, lapatinib, methotrexate, mitoxantrone, rosuvastatin, sulfasalazine, topotecan), OATP1B1 substrates (atorvastatin, bosentan, ezetimibe, fluvastatin, glyburide, olmesartan, pitavastatin, pravastatin, rosuvastatin, repaglinide, rifampin, simvastatin acid, valsartan):* Possibly increased risk of adverse reactions related to excessive exposure to these drugs

### FOODS

*all foods, especially dairy:* Decreased absorption of eltrombopag

## Adverse Reactions

**CNS:** Asthenia, chills, dizziness, fatigue, fever, headache, insomnia, paresthesia

**CV:** Arterial and venous thromboembolism, peripheral edema, primary portal venous system thromboses (in presence of chronic liver disease)

**EENT:** Cataract, conjunctival hemorrhage, nasopharyngitis, oropharyngeal pain, pharyngitis, rhinitis, rhinorrhea, toothache

**GI:** Abdominal pain, anorexia, diarrhea, dyspepsia, elevated bilirubin or liver enzymes, hepatic decompensation with antiviral and interferon therapy, hepatotoxicity, indirect hyperbilirubinemia (with antiviral and interferon therapy), nausea, vomiting

**GU:** Acute renal failure with thrombotic microangiopathy, menorrhagia, UTI

**HEME:** Anemia, aplastic anemia, febrile neutropenia, hemorrhage, thrombocytopenia

**MS:** Arthralgia, back or extremity pain, muscle spasm, myalgia

**RESP:** Cough, dyspnea, upper respiratory tract infection

**SKIN:** Alopecia, ecchymosis, pruritus, rash, skin discoloration including hyperpigmentation and skin yellowing

**Other:** Flu-like symptoms

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug is not recommended for use during pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## Nursing Considerations

- Know that eltrombopag should not be used to treat any other kind of thrombocytopenia because of the risk of hematologic malignancies or portal venous system thromboses in patients with chronic liver disease. Also, know the drug should not be used to treat myelodysplastic syndromes because of an increased risk of progression to acute myeloid leukemia which could be fatal.
- Be aware that eltrombopag can be used only through a restricted distribution program called *Promacta Cares*. Patient, pharmacy, and prescriber must all be enrolled before therapy begins.
- Use cautiously in patients with hepatic impairment because drug may cause hepatotoxicity and arterial and venous thrombosis, although most are portal venous system thromboses. This is especially important if patient with hepatic impairment also has risk factors present for thromboembolism.
- Monitor bilirubin level and liver enzymes, as ordered, before starting eltrombopag, every 2 weeks during dosage adjustment, and monthly once dose is stable except for treatment for first line treatment of severe aplastic anemia. For this indication, monitor bilirubin level and liver enzymes, as ordered, before starting eltrombopag, every other day while hospitalized for horse antithymocyte globulin (h-ATG) therapy, and then every 2 weeks during treatment. If abnormalities occur, repeat testing within 3 to 5 days and then weekly until liver enzymes return to baseline. Expect to discontinue drug if alanine aminotransferase level (ALT) increases to 3 or more times the upper normal limit, progresses or persists for 4 or more weeks, or is accompanied by an increase in direct bilirubin or clinical symptoms of liver injury.
- Know that there is an increased risk of hepatic decomposition when eltrombopag is used in combination with interferon and ribavirin in patients with chronic hepatitis C. Monitor these patients closely for evidence of hepatic dysfunction.
- Expect to monitor platelet counts every week prior to starting antiviral therapy, as ordered, for patient with hepatitis C. Once antiviral therapy has started, expect to monitor CBCs with differentials including platelet counts weekly during antiviral therapy until a stable platelet count is achieved. Thereafter, monitor platelet counts monthly, as ordered.

- Know that patient should have a baseline eye examination, as ordered, before starting eltrombopag and periodically throughout therapy, because drug may cause cataracts.
- Be aware that dosage adjustments are based on platelet count response and are not used to normalize platelet counts in order to prevent or minimize thrombotic complications.
- Give eltrombopag 1 hour before or 2 hours after the patient has eaten. Separate doses of other drugs by at least 4 hours to prevent drug interactions.
- Do not administer more than one dose of eltrombopag within any 24-hour period because too much drug increases the patient's risk of thrombotic events.
- Expect to discontinue drug for patient with chronic thrombocytopenia if improvement doesn't occur within 4 weeks at maximum dose of 75 mg daily or if the platelet count remains greater than  $400 \times 10^9/L$  after 2 weeks of therapy at the lowest dose of eltrombopag. Expect to discontinue drug for patient with hepatitis C if the platelet count remains greater than  $400 \times 10^9/L$  after 2 weeks of therapy at the lowest dose of eltrombopag or when antiviral therapy is discontinued. Expect to discontinue drug for patient with severe aplastic anemia if improvement doesn't occur after 16 weeks of therapy.
- Monitor patient for hematologic malignancies because eltrombopag stimulates thrombopoietin receptor on the surface of hematopoietic cells, which increases risk of malignancies.
- Monitor patient for increased bleeding after stopping eltrombopag because thrombocytopenia may worsen, increasing bleeding risk, especially if patient is on anticoagulants or antiplatelet therapy. If bleeding occurs, obtain weekly CBC, including platelet count, for at least 4 weeks after therapy stops, and provide supportive care, as indicated and ordered.

## PATIENT TEACHING

- Inform patient that before eltrombopag therapy can begin, he must be enrolled in the *Promacta Cares* program, which provides comprehensive education about the drug.
- Urge patient to tell prescriber about all health conditions and all prescribed drugs, OTC drugs, herbs, and supplements taken.

- Tell patient to prepare the prescribed oral suspension using water only, but not hot water, and to ingest immediately after preparation. Any suspension not used should be discarded within 30 minutes. Remind patient that a new oral dosing syringe should be used to prepare every dose of oral suspension.
- Instruct patient to take eltrombopag on an empty stomach with a full glass of water 1 hour before or 2 hours after a meal and to separate use of other drugs by at least 4 hours because food and certain drugs (such as antacids and iron and vitamin supplements) may interfere with eltrombopag absorption.
- Instruct patient to take drug at the same time every day because no more than one dose should be taken within any 24-hour period because too much of the drug may cause blood clots.
- Encourage patient to have regular eye exams because drug may increase the development of cataracts.
- Urge patient to report any adverse reactions, especially signs and symptoms of liver problems such as confusion, right upper stomach area pain or swelling, tiredness or unusual darkening of the urine, or yellowing of the skin or the whites of the eyes, to prescriber. In addition, tell patient to keep all appointments for blood work and follow-up.
- Review bleeding precautions with patient. Tell him that he may be at increased risk for bleeding and should follow bleeding precautions even after drug is discontinued, especially if he is also taking a drug that affects the ability to clot. He should seek medical attention if serious bleeding occurs.
- Inform women of childbearing age to use effective contraception throughout eltrombopag therapy and for at least 7 days after drug is discontinued, because drug may cause fetal harm. If pregnancy is suspected or occurs, prescriber should be notified immediately.
- Tell mothers wishing to breastfeed that breastfeeding is not recommended during eltrombopag therapy, because drug may transfer to infant during breastfeeding and has the potential to cause serious adverse reactions in the breastfed child.

# eluxadoline

## Viberzi

---

## Class, Category, and Schedule

*Pharmacologic class:* Mu-opioid receptor agonist

*Therapeutic class:* Antidiarrheal

*Controlled substance schedule:* IV

## Indications and Dosages

- *To treat irritable bowel syndrome with diarrhea (IBS-D)*

### **TABLETS**

**Adults.** 100 mg twice daily with food.

***DOSAGE ADJUSTMENT*** For patients who are unable to tolerate the 100-mg dose, who are receiving concomitant OATP1B1 inhibitors, or who have mild to moderate hepatic impairment, dosage reduced to 75 mg twice daily.

## Mechanism of Action

Interacts with opioid receptors in the intestines to relieve diarrhea.

## Contraindications

Absence of a gallbladder, alcoholism, or patients who drink more than three alcoholic beverages daily, biliary duct obstruction, history of pancreatitis or structural disease of the pancreas, history of chronic or severe constipation, hypersensitivity to eluxadoline or its components, known or suspected mechanical gastrointestinal obstruction, severe

hepatic impairment, sphincter of Oddi disease, or dysfunction

## Interactions

### DRUGS

*alosetron, anticholinergics, opioids or other drugs that cause constipation:* Increased risk of constipation and constipation-related adverse reactions

*OATP1B1 inhibitors such as antivirals, cyclosporine, eltrombopag, gemfibrozil, rifampin:* Increased exposure to eluxadolone increasing risk of adverse reactions

*rosuvastatin:* Increased exposure to rosuvastatin with increased risk for myopathy and rhabdomyolysis

### ACTIVITIES

*alcohol use:* Increased risk for acute pancreatitis

## Adverse Reactions

**CNS:** Dizziness, euphoria, fatigue, sedation, sensation of feeling drunk, somnolence

**CV:** Chest pain or tightness

**EENT:** Nasopharyngitis, **throat tightness**

**GI:** Abdominal distention or pain, constipation (which may become severe), elevated liver enzymes, flatulence, gastroesophageal reflux disease, nausea, **pancreatitis**, sphincter of Oddi spasm, vomiting

**RESP:** **Asthma**, bronchitis, **bronchospasm**, dyspnea, **respiratory failure**, upper respiratory infection, wheezing

**SKIN:** Pruritus, rash, urticaria

**Other:** Anaphylaxis, angioedema

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Assess patient's alcohol intake prior to starting eluxadoline therapy. Also, question patient about gallbladder removal surgery, as drug is contraindicated in patients without a gallbladder.

**WARNING** Monitor patient closely for hypersensitivity reactions that could include anaphylaxis, angioedema, difficulty breathing or swallowing, and skin reactions such as itching, rash, or urticaria. If present, notify prescriber immediately, stop administering drug, and provide emergency supportive care, as ordered.

- Monitor patient closely for acute abdominal pain, especially during the first few weeks of therapy, because mu-opioid receptor agonism increases risk for sphincter of Oddi spasm, which could result in elevated liver enzymes or pancreatitis. If present, notify prescriber and expect eluxadoline to be discontinued.
- Monitor patient's liver enzymes, as ordered and report any elevations to prescriber.

- Notify prescriber if patient develops severe constipation and expect drug to be discontinued. Severe cases of fecal impaction or intestinal obstruction or perforation have occurred with severe constipation, requiring emergency intervention.

## PATIENT TEACHING

- Tell patient that if she misses a dose to take the next dose at the regular time and not to double up the dose to make up for a missed dose.
- Warn patient against acute excessive or chronic alcohol intake while taking eluxadoline.
- Instruct patient to stop taking eluxadoline and immediately seek medical attention if she experiences acute epigastric or right, upper quadrant abdominal pain that may radiate to the back or shoulder and may be accompanied by nausea and vomiting.
- Tell patient to notify prescriber immediately if she develops severe constipation and not to use other drugs that may cause constipation during eluxadoline therapy.
- Advise patient to inform all prescribers of eluxadoline therapy.
- Tell patient not to take other drugs to treat diarrheal symptoms unless prescribed and the prescriber is aware of eluxadoline use.

**elvitegravir**

**Vitekta**

## Class and Category

*Pharmacologic class:* Integrase inhibitor

*Therapeutic class:* Antiretroviral

## Indications and Dosages

- *As adjunct to treat human immunodeficiency virus type 1 (HIV-1) in antiretroviral treatment-experienced patients*

## **TABLETS**

**Adults taking atazanavir and ritonavir concurrently.** 85 mg once daily with food with atazanavir 300 mg once daily and ritonavir 100 mg once daily.

**Adults taking lopinavir and ritonavir concurrently.** 85 mg once daily with food with lopinavir 400 mg twice daily and ritonavir 100 mg twice daily.

**Adults taking darunavir and ritonavir concurrently.** 150 mg once daily with food with darunavir 600 mg twice daily and ritonavir 100 mg twice daily.

**Adults taking fosamprenavir and ritonavir concurrently.** 150 mg once daily with food with fosamprenavir 700 mg twice daily and ritonavir 100 mg twice daily.

**Adults taking tipranavir and ritonavir concurrently.** 150 mg once daily with food with tipranavir 500 mg twice daily and ritonavir 200 mg twice daily.

## **Mechanism of Action**

Inhibits HIV integrase by binding to the integrase active site and blocking the strand transfer step of retroviral DNA integration, which is needed for the HIV replication cycle.

## **Contraindications**

Concurrent use with combination drugs that contain elvitegravir, hypersensitivity to elvitegravir, or its components

# Interactions

## DRUGS

*antacids, carbamazepine, dexamethasone, efavirenz, nevirapine, oxcarbazepine, phenobarbital, phenytoin, rifampin, rifapentine, St. John's wort:* Decreased plasma elvitegravir concentrations, lowering drug's effectiveness

*atazanavir, lopinavir/ritonavir:* Increased plasma elvitegravir levels, increasing risk of serious adverse reactions

*boceprevir, methadone, naloxone, telaprevir:* Decreased plasma concentrations of these drugs, reducing effectiveness

*bosentan:* Increased plasma concentration of bosentan, possibly increasing risk of serious adverse reactions and decreased plasma concentration of elvitegravir that decreases its effectiveness

*buprenorphine:* Increased buprenorphine concentration and increased risk of adverse cognitive effects and sedation

*ethinyl estradiol:* Decreased plasma concentration of ethinyl estradiol, leading to decreased contraception effectiveness

*HIV protease inhibitors:* Decreased or increased plasma concentrations of these drugs, which can reduce effectiveness and possibly lead to development of resistance

*ketoconazole:* Increased plasma concentrations of both drugs, increasing risk of serious adverse reactions

*rifabutin:* Increased plasma concentration of rifabutin, possibly increasing risk of serious adverse reactions and

decreased plasma concentration of elvitegravir that decreases its effectiveness

## Adverse Reactions

**CNS:** Depression, fatigue, headache, insomnia, **suicidal ideation**

**CV:** Elevated cholesterol and triglycerides

**ENDO:** Hyperglycemia

**GI:** Abdominal pain; diarrhea; dyspepsia; elevated amylase, bilirubin, or liver enzymes; nausea; vomiting

**GU:** Hematuria, glycosuria

**HEME:** **Neutropenia**

**MS:** Elevated creatine kinase

**SKIN:** Rash

**Other:** Immune reconstitution syndrome

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of

HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## Nursing Considerations

- Know that the fixed-dose combination drug, Stribild, should not be administered with elvitegravir because elvitegravir is a component of the combination, which could increase the risk of serious adverse reactions.
- Be aware that cobicistat should not be given to patients receiving elvitegravir, because it may cause elvitegravir to be less effective.

**WARNING** Take a complete drug history, because risk of adverse reactions that may result in serious adverse reactions from greater exposures of concomitant drugs or elvitegravir may occur. Some drug interactions may also cause elvitegravir to become less effective. Make all prescribers aware of patient's use of elvitegravir.

- Monitor patient closely for suicidal ideation.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including elvitegravir. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.

## PATIENT TEACHING

- Instruct patient to take elvitegravir exactly as prescribed and with food. Tell patient that other drugs will have to be taken with elvitegravir to enhance its effectiveness.
- Warn patient to check with prescriber before taking any new medications, including over-the-counter and herbal preparations.
- Instruct family or caregiver to watch patient closely for evidence of suicidal behavior or thinking.

- Tell patient to report any persistent, severe, or unusual signs and symptoms to prescriber, including signs of infection.
- Stress importance of alerting prescriber if pregnancy occurs or is suspected.
- Inform mothers that breastfeeding should not be done while taking elvitegravir, because drug does appear in human breast milk.

## empagliflozin

### Jardiance

## Class and Category

*Pharmacologic class:* Sodium glucose co-transporter 2 inhibitor

*Therapeutic class:* Antidiabetic

## Indications and Dosages

- Adjunct to diet and exercise to improve glycemic control in patients with type 2 diabetes mellitus; to reduce risk of cardiovascular death in patients with type 2 diabetes mellitus who have established cardiovascular disease

### **TABLETS**

**Adults.** 10 mg once daily in morning, increased to 25 mg once daily in morning, as needed.

## Mechanism of Action

Inhibits sodium glucose co-transporter 2 in the kidneys, which prevents glucose reabsorption. This decreases blood glucose levels.

## Contraindications

Dialysis therapy, end-stage renal disease, hypersensitivity to empagliflozin or its components, severe renal impairment

## Interactions

### DRUGS

*diuretics*: Increased risk of acute kidney injury and renal impairment in presence of dehydration

*insulin, insulin secretagogues*: Increased risk of hypoglycemia

## Adverse Reactions

**CNS**: Syncope

**CV**: Dyslipidemia, elevated low-density lipoprotein cholesterol, **hypotension**

**ENDO**: **Ketoacidosis**

**GI**: Nausea

**GU**: **Acute kidney injury**, decreased glomerular filtration rate, dysuria, elevated serum creatinine levels, genital mycotic infections, impaired renal function, increased urination, osmotic diuresis, pyelonephritis, **urosepsis**, UTI

**MS**: Arthralgia, increased risk of bone fracture

**RESP**: Upper respiratory tract infection

**SKIN**: Rash, urticaria

**Other**: **Angioedema**, dehydration

# Childbearing Considerations

## PREGNANCY

- Drug may cause adverse renal effects to the developing fetus.
- Drug is not recommended for use during the second and third trimester of pregnancy.

## LACTATION

- It is not known if drug is present in breast milk.
- Women should not breastfeed their infant while taking drug because kidney maturation continues through the first 2 years of life.

# Nursing Considerations

- Assess patient's volume status and correct, if needed and as prescribed, prior to starting empagliflozin therapy because drug can cause intravascular volume contraction leading to symptomatic hypotension and acute kidney injury. Continue to monitor patient throughout therapy for dehydration and renal dysfunction. Patients at highest risk include the elderly and patients with chronic renal insufficiency, congestive heart failure, and hypovolemia or patients who take diuretics. Notify prescriber immediately if patient has fluid losses or reduced oral intake, as acute kidney injury may occur. Expect that drug may be temporarily withheld until fluid balance can be restored.
- Obtain serum creatinine level, as ordered, prior to starting empagliflozin therapy because empagliflozin can cause adverse renal effects. Be aware that the elderly and patients with existing impaired renal function are at higher risk for these adverse effects. Monitor renal function throughout therapy.
- Monitor patient for hypersensitivity reactions that could be serious, such as the development of angioedema. If present, withhold drug, notify prescriber immediately, and be prepared to provide emergency supportive care, as ordered.
- Monitor patient's blood pressure and cholesterol level throughout empagliflozin therapy.

- Be aware that patients receiving insulin or insulin secretagogues may require a lower dose of these agents because empagliflozin in combination increases risk of hypoglycemia. Monitor patient closely for hypoglycemia. If present, treat according to standard of care and notify prescriber.

**WARNING** Monitor patient closely for ketoacidosis that have occurred in patients with type 2 diabetes being treated with empagliflozin. Be aware that ketoacidosis can become life-threatening quickly even when blood glucose levels are less than 250 mg/dl. Notify prescriber immediately if ketoacidosis is suspected and expect drug to be discontinued. Be prepared to treat patient's ketoacidosis, as ordered. Be aware that patients at higher risk include patients with a history of alcohol abuse or who have a pancreatic insulin deficiency from any cause or have reduced caloric intake. Expect drug to be temporarily discontinued if patient must undergo prolonged fasting due to acute illness or surgery.

- Monitor patients for genital mycotic infections or urinary tract infections, especially those with a history of such. If present, notify prescriber and treat, as prescribed.

**WARNING** Monitor patient for a rare but serious and life-threatening necrotizing infection of the perineum called Fournier's gangrene. Notify prescriber immediately if patient develops erythema, pain, swelling, or tenderness in the genital or perineal area, along with fever or malaise. Expect treatment with broad-spectrum antibiotics and, if needed, surgical debridement of the area. Know that empagliflozin will be discontinued if this occurs. Monitor patient's blood glucose levels closely and expect an alternative treatment for glycemic control.

## **PATIENT TEACHING**

- Inform patient that empagliflozin therapy is not a replacement for diet and exercise therapy.
- Tell patient that drug may cause an allergic reaction such as swelling of the eyes, face, throat, and tongue. It may also cause skin reactions such as a rash or hives. If present, stress importance of stopping drug and seeking immediate emergency medical treatment.
- Instruct patient on the signs and symptoms of hypoglycemia and how to treat it. Inform patient who is also receiving insulin or a sulfonylurea that the risk of hypoglycemia is greater. Tell patient to notify prescriber if hypoglycemia occurs frequently or is severe.
- Tell patient to monitor the blood glucose level using blood tests instead of urine tests because drug increases urinary glucose excretion and will lead to positive urine glucose tests.
- Review signs and symptoms of ketoacidosis with patient and urge her to seek immediate medical attention, if present, even if blood glucose level is less than 250 mg/dl.
- Advise female patients to notify prescriber if pregnancy occurs or is suspected. Also advise women that breastfeeding is not recommended while taking empagliflozin.
- Advise patient to maintain adequate fluid intake throughout empagliflozin therapy. However, tell patient to notify prescriber if she is unable to take a normal amount of daily fluids due to fasting or illness or experiences an excessive loss of fluids from excessive perspiration or gastrointestinal illnesses. Drug may have to be temporarily withheld.
- Stress importance of notifying prescriber if patient develops dehydration, has onset of hunger or thirst, or notices a sudden change in mental status. Tell patient not to belittle these symptoms and seek medical attention quickly.

**WARNING** Warn patient to stop empagliflozin and seek immediate medical attention if pain, redness, swelling, or tenderness occurs in the genital or perineal area, along with fever or malaise because, although rare, this cluster of symptoms may become life-threatening.

- Teach patient to take fall precautions and other safety measures because drug may increase risk of bone fracture as early as 12 weeks after empagliflozin therapy is begun.

# emtricitabine

**Emtriva**

## Class and Category

*Pharmacologic class:* Nucleoside analogue

*Therapeutic class:* Antiretroviral

## Indications and Dosages

- *As adjunct to treat human immunodeficiency virus type 1 (HIV-1) infection*

### CAPSULES, ORAL SOLUTION

**Adults.** 200 mg (capsule) or 240 mg (oral solution) once daily.

**Children ages 3 months to 18 years who weigh more than 33 kg (72.6 lb) and can swallow an intact capsule.** 200 mg once daily.

**Children ages 3 months to 18 years prescribed oral solution.** 6 mg/kg up to maximum of 240 mg once daily.

**Newborns and infants up to 3 months.** 3 mg/kg (oral solution) once daily.

***DOSAGE ADJUSTMENT*** For adult patients with a creatinine clearance of 30 to 49 ml/min, dosage interval increased to every 48 hr if using capsules or dosage reduced to 120 mg once daily if using oral solution. For adult patients with a creatinine clearance of 15 to 29 ml/min, dosage interval increased to every 72 hr if using capsules or dosage

reduced to 80 mg once daily if using oral solution. For adult patients with a creatinine clearance of less than 15 ml/min or who are on hemodialysis, dosage interval increased to every 96 hr if using capsules or dosage reduced to 60 mg once daily if using oral solution. For pediatric patients with renal impairment, there is insufficient data to recommend a specific dose adjustment, but a reduction in dose and/or an increase in dosing interval similar to adults may be considered.

## **Mechanism of Action**

Phosphorylated by cellular enzymes, emtricitabine then inhibits the activity of the HIV-1 reverse transcriptase by competing with the natural substrate and by being incorporated into the nascent viral DNA, which leads to chain termination of the HIV virus.

## **Contraindications**

Hypersensitivity to emtricitabine or its components

## **Interactions**

### **DRUGS**

None reported

## **Adverse Reactions**

**CNS:** Abnormal dreams, asthenia, depression, dizziness, fatigue, fever, headache, insomnia, neuropathy, paresthesia, peripheral neuritis

**CV:** Elevated cholesterol and triglycerides

**EENT:** Nasopharyngitis, otitis media, rhinitis, sinusitis

**ENDO:** Cushingoid appearance, fat redistribution, hyperglycemia

**GI:** Abdominal pain; diarrhea; dyspepsia; elevated amylase, bilirubin, lipase, and liver enzymes; gastroenteritis; nausea; **severe acute exacerbations of hepatitis B; severe hepatomegaly with steatosis**; vomiting

**GU:** Glycosuria, hematuria, new onset or worsening of renal impairment

**HEME:** Anemia, decreased hemoglobin, **neutropenia**

**MS:** Arthralgia, elevated creatine kinase, myalgia

**RESP:** Increased cough, pneumonia, upper respiratory infections

**SKIN:** Hyperpigmentation on palms and/or soles, pruritus, rash, urticaria

**Other:** Elevated alkaline phosphatase, immune reconstitution syndrome, infection, **lactic acidosis**

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug may be present in breast milk.

- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## Nursing Considerations

- Expect to test patient for hepatitis B virus (HBV) prior to starting emtricitabine, as ordered. This is because acute exacerbations of hepatitis B have occurred after patient has discontinued the drug. Know that in some cases the exacerbation resulted in liver failure.
- Monitor patient's liver enzymes throughout therapy and for several months after drug is discontinued, because lactic acidosis and severe hepatomegaly with steatosis have occurred with emtricitabine therapy, as have acute exacerbations of hepatitis B with patients coinfecting. Know that most cases of lactic acidosis and severe hepatomegaly with steatosis have occurred in women with prolonged nucleoside exposure and obesity. Report abnormal liver function signs and symptoms to prescriber, such as abdominal discomfort, jaundice, nausea, vomiting, or weakness.
- Perform a complete drug history on patient, because combination drugs containing emtricitabine (Atripla, Complera, Truvada) should not be given concurrently with emtricitabine therapy. Also, expect not to coadminister drugs containing lamivudine (Cobivir, Epivir, Epivir-HBV, Epzicom, Trizivir) because of the similarities between emtricitabine and lamivudine.
- Monitor patient's renal function, because drug is primarily eliminated by the kidney and dosage alterations are necessary for those with impaired kidney function.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including emtricitabine. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.

## PATIENT TEACHING

- Inform patient that emtricitabine will be prescribed along with other antiviral drugs.

- Review signs and symptoms of liver dysfunction (belly discomfort, nausea, vomiting, weakness, yellowing of skin or whites of eyes) and stress importance of reporting any occurrence to prescriber.
- Instruct patient to remind all prescribers of emtricitabine therapy.
- Inform patient that emtricitabine therapy may cause changes in his body appearance because of fat redistribution. Prepare him for the possibility of developing breast enlargement, central obesity, dorsocervical fat enlargement (buffalo hump), facial wasting, and peripheral wasting.
- Instruct patient to report any persistent, severe, or unusual signs and symptoms.
- Encourage women of childbearing age to report known or suspected pregnancy.
- Alert mothers that breastfeeding is not recommended during emtricitabine therapy, because drug is present in human breast milk.

## enalapril maleate

**Epaned, Vasotec**

enalaprilat

## Class and Category

*Pharmacologic class:* Angiotensin converting enzyme (ACE) inhibitor

*Therapeutic class:* Antihypertensive, vasodilator

## Indications and Dosages

➤ *To control hypertension*

## ORAL SOLUTION, TABLETS

**Adults.** *Initial:* 5 mg daily, increased after 1 to 2 wk, as needed. *Maintenance:* 10 to 40 mg once daily or in divided doses twice daily. *Maximum:* 40 mg daily.

**Children older than 1 month.** 0.08 mg/kg daily, titrated according to blood pressure response up to 5 mg daily. *Maximum:* 0.58 mg/kg/dose or 40 mg/dose.

## I.V. INFUSION

**Adults.** 1.25 mg over 5 min every 6 hr.

**DOSAGE ADJUSTMENT** Initial dose reduced to 2.5 mg P.O. or 0.625 mg I.V. for patients who have sodium and water depletion from diuretic therapy, are receiving diuretics, or adults who have a creatinine clearance below 30 ml/min (not used in children who have a glomerular filtration rate below 30 ml/min). For patient who is receiving a diuretic, if response to I.V. dose is inadequate after 1 hr, I.V. dose of 0.625 mg repeated and therapy continued at 1.25 mg every 6 hr.

➤ *To convert from IV to oral dosage form*

**Patients not currently receiving diuretics.** *Initial:* 5 mg daily then increased as needed.

**Patients currently receiving diuretics and responding to 0.625 mg IV every 6 hr.** *Initial:* 2.5 mg daily, then increased as needed.

➤ *To treat symptomatic heart failure*

## TABLETS

**Adults.** *Initial:* 2.5 mg twice daily, increased after 1 to 2 wk, as needed.

*Maintenance:* 5 to 40 mg daily in 2 divided doses.

**DOSAGE ADJUSTMENT** For patients with hyponatremia (serum sodium less than 130 mEq/L) or serum creatinine greater

than 1.6 mg/dl, initial dosage reduced to 2.5 mg once daily.

- *To treat asymptomatic left ventricular dysfunction, to decrease the rate of development of overt heart failure and reduce hospitalization for heart failure*

## TABLETS

**Adults.** *Initial:* 2.5 mg twice daily, increased to 20 mg daily in 2 divided doses.

***DOSAGE ADJUSTMENT*** Initial dosage reduced to 2.5 mg daily in patients who have a creatinine clearance of 30 ml/min or below.

Route	Onset	Peak	Duration
P.O.	1 hr	4-6 hr	About 24 hr
I.V.	15 min	1-4 hr	About 6 hr

## Mechanism of Action

May reduce blood pressure and development of heart failure by affecting the renin-angiotensin-aldosterone system. By inhibiting angiotensin-converting enzyme (ACE), enalapril:

- prevents conversion of angiotensin I to angiotensin II, a potent vasoconstrictor that also stimulates the adrenal cortex to secrete aldosterone
- may inhibit renal and vascular production of angiotensin II
- decreases the serum angiotensin II level and increases serum renin activity, which decreases aldosterone secretion and slightly increases serum potassium level and fluid loss
- decreases vascular tone and blood pressure
- inhibits aldosterone release, which reduces sodium and water reabsorption and increases their excretion, further reducing blood pressure and development of heart failure.

# Contraindications

Concurrent aliskiren therapy in patients with diabetes; concurrent therapy with a neprilysin inhibitor such as sacubitril, history of hereditary or idiopathic angioedema; hypersensitivity to enalapril, enalaprilat, other ACE inhibitors, or their components; use within 36 hours of sacubitril/valsartan therapy

# Interactions

## DRUGS

*aliskiren, angiotensin receptor blockers, other ACE inhibitors:* Increased risk of hyperkalemia, hypotension, and renal dysfunction

*diuretics, other antihypertensives:* Additive hypotensive effects

*lithium:* Increased blood lithium level and lithium toxicity

*mTOR inhibitors (everolimus, sirolimus, temsirolimus);*

*neprilysin inhibitor (sacubitril):* Increased risk of angioedema

*NSAIDs including selective cyclooxygenase-2 inhibitors:* Possibly reduced antihypertensive effects of enalapril and enalaprilat; possibly increased risk of renal dysfunction, especially in the elderly or who are volume-depleted or already have compromised renal function

*potassium-sparing diuretics, potassium supplements:* Increased risk of hyperkalemia

*sodium aurothiomalate:* Increased risk of nitritoid reactions, such as facial flushing, nausea, vomiting, and hypotension

*thiazide diuretics:* Increased loss of potassium

## FOODS

*potassium-containing salt substitutes*: Increased risk of hyperkalemia

## Adverse Reactions

**CNS:** Ataxia, confusion, CVA, depression, dizziness, dream disturbances, fatigue, headache, insomnia, nervousness, peripheral neuropathy, somnolence, syncope, vertigo, weakness

**CV:** Angina, **arrhythmias**, **cardiac arrest**, **hypotension**, **MI**, orthostatic hypotension, palpitations, Raynaud's phenomenon

**EENT:** Blurred vision, conjunctivitis, dry eyes and mouth, glossitis, hoarseness, lacrimation, loss of smell, pharyngitis, rhinorrhea, stomatitis, taste perversion, tinnitus

**ENDO:** Gynecomastia

**GI:** Abdominal pain, anorexia, constipation, diarrhea, **hepatic failure**, **hepatitis**, ileus, indigestion, **melena**, nausea, **pancreatitis**, vomiting

**GU:** Flank pain, impotence, oliguria, **renal failure**, UTI

**MS:** Muscle spasms

**RESP:** Asthma, bronchitis, **bronchospasm**, cough, dyspnea, pneumonia, **pulmonary edema**, **pulmonary embolism and infarction**, **pulmonary infiltrates**, upper respiratory tract infection

**SKIN:** Alopecia, diaphoresis, **erythema multiforme**, **exfoliative dermatitis**, flushing, pemphigus, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, herpes zoster, **hyperkalemia**

# Childbearing Considerations

## PREGNANCY

- Drug may cause adverse renal effects to the developing fetus, especially in the second and third trimester.
- Drug should be discontinued when pregnancy is known.

## LACTATION

- Drug is present in breast milk.
- Women should not breastfeed their infant while taking drug because kidney maturation continues through the first 2 years of life.

# Nursing Considerations

- Use enalapril and enalaprilat cautiously in patients with impaired renal function. Avoid giving drug to children with a GFR less than 30 ml/min.
- For adults or children who can't swallow tablets, consult with prescriber and pharmacist about preparing an oral suspension from tablets as directed by manufacturer. Alternatively, have prescriber order the oral solution form (Epaned).
- Reconstitute oral solution by tapping bottle containing the drug powder on a hard surface 5 times to loosen powder. Add about half (75 ml) of the Ora-Sweet SF diluent that comes with the drug to the powder bottle. Replace cap and shake well for 30 seconds. Reopen and add remainder diluent to the drug powder bottle. Replace cap and shake well again for 30 seconds. Calculate 60 days from the date of reconstitution and write this date as the discard date on the front of the label.
- Administer each I.V. dose over at least 5 minutes.
- Measure patient's blood pressure immediately after first dose and frequently for at least 2 hours thereafter. If hypotension requires a dosage reduction, monitor blood pressure frequently for 2 hours after reduced dosage is administered and for another hour after blood pressure has stabilized.
- Monitor blood pressure regularly during therapy. If hypotension develops, place patient in a supine position and expect to give I.V. normal saline

solution or other volume expander as prescribed.

- Monitor patient's heart rate and rhythm. Expect to obtain repeated 12-lead ECG tracings.
- Monitor laboratory test results to check hepatic and renal function, leukocyte count, and serum potassium level.
- Monitor patient closely for angioedema of the face, glottis, larynx, limbs, lips, and tongue. Notify prescriber and stop drug administration immediately. Expect to give an antihistamine, as prescribed. If glottis, larynx, or tongue is involved, assess patient for airway obstruction and prepare to give epinephrine 1:1,000 (0.3 to 0.5 ml) subcutaneously and maintain a patent airway.

## PATIENT TEACHING

- Advise patient to take drug at the same time each day.
- Instruct patient not to chew, crush, or split tablets.
- Teach patient how to mix oral solution, if prescribed.
- Inform patient that fainting and light-headedness may occur, especially during first few days of therapy. Advise him to change position slowly and avoid hazardous activities until drug's CNS effects are known.
- Inform patient that diarrhea, excessive sweating, vomiting, and other conditions may cause dehydration, which can lead to dizziness, fainting, and very low blood pressure during therapy. Urge sufficient fluid intake to prevent dehydration and related adverse reactions. If diarrhea or vomiting is severe or prolonged, instruct patient to notify prescriber.
- Urge patient to stop taking drug and immediately seek emergency care if swelling of extremities, face, lips, throat, or tongue occurs. Also tell patient to notify prescriber if other adverse reactions, including persistent dry cough, occur.
- Advise patient to consult prescriber before using potassium supplements, salt substitutes, or other drugs (including OTC drugs) while taking drug.

**WARNING** Caution women of childbearing age that they should use a reliable form of contraception and should notify prescriber immediately if pregnancy is suspected because enalapril may cause fetal harm and should be discontinued.

# enfuvirtide

## Fuzeon

### Class and Category

*Pharmacologic class:* Fusion inhibitor

*Therapeutic class:* Antiretroviral

### Indications and Dosages

- *As adjunct to treat human immunodeficiency virus type 1 (HIV-1) infection*

### SUBCUTANEOUS INJECTION

**Adults and adolescents ages 17 and over.** 90 mg twice daily.

**Children ages 6 to 17 weighing at least 11 kg (24.2 lb).** 2 mg/kg twice daily. *Maximum:* 90 mg twice daily.

### Mechanism of Action

Interferes with the entry of HIV-1 into cells to inhibit fusion of cellular membranes with the virus. It does this by binding to the viral envelope glycoprotein and preventing the conformational changes required for the fusion.

### Contraindications

Hypersensitivity to enfuvirtide or its components

# Interactions

## DRUGS

None reported

## Adverse Reactions

**CNS:** Anxiety, asthenia, chills, depression, fatigue, fever, **Guillain-Barré syndrome**, insomnia, peripheral neuropathy, rigors, sixth nerve palsy, **suicidal ideation**

**CV:** Elevated triglycerides, **hypotension**, **unstable angina pectoris**

**EENT:** Conjunctivitis, dry mouth, sinusitis, taste disturbance

**ENDO:** Hyperglycemia

**GI:** Anorexia; constipation; diarrhea; elevated amylase, lipase, and liver enzymes; hepatic steatosis; nausea; **pancreatitis**; **toxic hepatitis**; upper abdominal pain; vomiting

**GU:** **Glomerulonephritis**, **renal failure or insufficiency**, **tubular necrosis**

**HEME:** Eosinophilia, **neutropenia**, **thrombocytopenia**

**MS:** Elevated creatine phosphokinase, extremity pain, myalgia

**RESP:** Cough, pneumonia (bacterial), respiratory distress

**SKIN:** Cutaneous amyloidosis at injection site, folliculitis, pruritus, rash

**Other:** Formation of anti-enfuvirtide antibodies, flu-like symptoms, herpes simplex infection, immune reconstitution syndrome, local injection site reactions (bruising, cyst

formation, discomfort, ecchymosis, erythema, hematomas, **hypersensitivity reaction**, induration, infection, neuralgia, nodule formation, pain, paresthesia, pruritus), lymphadenopathy, post-injection bleeding, **sepsis**, weight loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## Nursing Considerations

- Reconstitute with 1 ml of sterile water for injection provided in the convenience kit. Then gently tap vial for 10 seconds, followed by gently rolling vial between hands to avoid foaming and to ensure that all particles of drug are in contact with the liquid. Let vial stand until powder is completely dissolved, which may take up to 45 minutes. When ready to withdraw the drug from the vial and the solution is foamy or jelled, allow more time for it to dissolve. Once reconstituted, use immediately or keep refrigerated in the original vial for up to 24 hours. If refrigerated, allow reconstituted solution to come to room temperature before administration.

- Administer enfuvirtide subcutaneously into patient's abdomen, anterior thigh, or upper arm using the Biojector 2000 needle-free device or a needle and syringe.
- Rotate site of injections, avoiding injecting into any anatomical areas where large nerves course close to the skin; directly over a blood vessel; or into skin abnormalities such as bruises, burn sites, moles, near the navel, scar tissue, surgical scars, or tattoos.
- Assess patient's injection site for local adverse reactions, because most patients experience at least one local injection-site reaction. Be especially alert for infection such as cellulitis or a local infection. Provide supportive care, as ordered, to manage injection-site reactions.
- Monitor patient's respiratory status closely, as bacterial pneumonia may occur and be serious enough to warrant hospitalization. Be especially alert for pneumonia in patients with a high initial viral load, history of intravenous drug use, low initial CD4 lymphocyte count, prior history of lung disease, or who are smokers.
- Be alert for systemic hypersensitivity reactions associated with enfuvirtide therapy, which may include chills, fever, hypotension, nausea, rash, rigors, and vomiting. Elevated liver enzymes may also occur.
- Know that enfuvirtide may cause formation of anti-enfuvirtide antibodies, which may result in a false positive HIV test with an ELISA assay.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including enfuvirtide. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.
- Watch patient closely for suicidal ideation.

## PATIENT TEACHING

- Inform patient that enfuvirtide therapy will be used in conjunction with other antiretroviral agents.
- Review how to reconstitute enfuvirtide and how to properly store it if not used immediately. Remind patient that drug does not contain a preservative and therefore must be refrigerated and used within 24 hours after being reconstituted. If refrigerated, tell patient that drug must be brought naturally to room temperature before administering.

- Instruct patient on how to properly use the Biojector 2000 device used to administer enfuvirtide subcutaneously, if needed. Otherwise, instruct her on how to use a needle and syringe and how to give a subcutaneous injection.
- Tell patient that drug should only be injected into her abdomen, front of her thigh, or in her upper arms. Sites must be rotated and drug should not be injected into any abnormal skin area, including tattoos, not near the navel, and not over blood vessels or large nerves close to the skin such as the back or side of thigh or near the elbow, groin, or knee. Advise patient how to safely discard used equipment such as needles and syringes.
- Advise patient to alert prescriber to persistent or severe local injection-site adverse reactions, including any signs or symptoms of infection. Inform her that almost all patients experience at least one injection-site reaction.
- Review signs and symptoms of an allergic reaction with patient and stress importance of seeking immediate medical attention.
- Alert patient that enfuvirtide may produce antibodies that could give a false positive for HIV testing. Remind her to alert all healthcare professionals of enfuvirtide therapy.
- Instruct patient to report any persistent, severe, or unusual signs and symptoms.
- Encourage women of childbearing age to report known or suspected pregnancy.
- Alert mothers that breastfeeding is not recommended during enfuvirtide therapy.
- Tell patient to seek medical attention if she develops signs or symptoms suggestive of pneumonia, such as cough with fever, rapid breathing, or shortness of breath.
- Caution patient and family that drug may cause suicidal thoughts. If present, prescriber should be notified.

## enoxaparin sodium

### **Lovenox**

## Class and Category

*Pharmacologic class:* Low-molecular-weight heparin

*Therapeutic class:* Anticoagulant

## Indications and Dosages

- *To prevent deep vein thrombosis (DVT) after hip or knee replacement and for continued prophylaxis after hospital-ization for hip replacement*

### SUBCUTANEOUS INJECTION

**Adults.** 30 mg every 12 hr, starting 12 to 24 hr after surgery for 7 to 10 days. Or, 40 mg daily, starting 9 to 15 hr after hip replacement surgery for up to 3 wk.

***DOSAGE ADJUSTMENT*** For patients with severe renal impairment (creatinine clearance less than 30 ml/min), dosage interval increased to once daily.

- *To prevent DVT after abdominal surgery for patients with thrombo-embolic risk factors*

### SUBCUTANEOUS INJECTION

**Adults.** 40 mg once daily, starting 2 hr before surgery and lasting 7 to 10 days.

***DOSAGE ADJUSTMENT*** For patients with severe renal impairment (creatinine clearance less than 30 ml/min), dosage reduced to 30 mg and dosage interval increased to once daily.

- *To prevent DVT in medical patients who are at risk for thromboembolic complications due to severely restricted mobility during acute illness*

### SUBCUTANEOUS INJECTION

**Adults.** 40 mg once daily for 6 to 11 days.

**DOSAGE ADJUSTMENT** For patients with severe renal impairment (creatinine clearance less than 30 ml/min), dosage reduced to 30 mg and dosage interval increased to once daily.

- *To treat DVT for inpatients with or without pulmonary embolism*

## **SUBCUTANEOUS INJECTION**

**Adults.** 1 mg/kg every 12 hr or 1.5 mg/kg once daily for a minimum of 5 days after warfarin therapy has been initiated and a therapeutic oral anticoagulant effect has been achieved. *Usual duration:* 7 days.

**DOSAGE ADJUSTMENT** For patient with severe renal impairment (creatinine clearance less than 30 ml/min) and taking warfarin concomitantly, dosage kept at 1 mg/kg and dosage interval increased to once daily.

- *To treat DVT as outpatient without pulmonary embolism*

## **SUBCUTANEOUS INJECTION**

**Adults.** 1 mg/kg every 12 hr for a minimum of 5 days after warfarin therapy has been initiated and a therapeutic oral anticoagulant effect has been achieved. *Usual duration:* 7 days.

**DOSAGE ADJUSTMENT** For patients with severe renal impairment (creatinine clearance less than 30 ml/min) and taking warfarin concomitantly, dosage interval increased to once daily.

- *To prevent ischemic complications of unstable angina and non-Q-wave MI*

## **SUBCUTANEOUS INJECTION**

**Adults.** 1 mg/kg every 12 hr with 100 to 325 mg of aspirin daily for 2 to 8 days or until condition is stable.

**DOSAGE ADJUSTMENT** For patients with severe renal impairment (serum creatinine less than 30 ml/min) when administered in conjunction with aspirin, dosage interval increased to once daily.

➤ *To treat acute ST-segment-elevation MI (STEMI)*

## **I.V. INJECTION, THEN SUBCUTANEOUS INJECTION**

**Adults.** 30 mg I.V. as a single dose plus 1 mg/kg subcutaneously. Then, 1 mg/kg subcutaneously every 12 hr (maximum 100 mg for first 2 doses).

**DOSAGE ADJUSTMENT** For patient with STEMI who is also receiving a thrombolytic, enoxaparin should be given between 15 min before and 30 min after fibrinolytic therapy starts. If STEMI patient has percutaneous coronary intervention, expect to give 0.3-mg/kg I.V. bolus if last enoxaparin dose was given more than 8 hr before balloon inflation. For patients less than 75 years of age with STEMI and severe renal impairment (less than 30 ml/min) when administered in conjunction with aspirin, 30 mg as a single IV bolus plus a 1 mg subcutaneous dose followed by 1 mg/kg subcutaneously once daily. For elderly patients with STEMI who are 75 years of age and older, initial I.V. bolus eliminated and initial subcutaneous injection dosage reduced to 0.75 mg/kg every 12 hr (maximum 75 mg for the first 2 doses only, followed by 0.75 mg/kg for remaining doses). For elderly patients 75 years and older who also have severe renal impairment (creatinine clearance less than 30 ml/min) and concurrent aspirin therapy is taken, dosage interval increased to once daily.

---

Route	Onset	Peak	Duration
-------	-------	------	----------

Route	Onset	Peak	Duration
SubQ	Unknown	3-5 hr	Up to 24 hr

## Mechanism of Action

Potentiates the action of antithrombin III, a coagulation inhibitor. By binding with antithrombin III, enoxaparin rapidly binds with and inactivates clotting factors (primarily factor Xa and thrombin). Without thrombin, fibrinogen can't convert to fibrin and clots can't form.

## Incompatibilities

Don't mix enoxaparin with other I.V. fluids or drugs.

## Contraindications

Active major bleeding; history of immune-mediated heparin-induced thrombocytopenia (HIT) within past 100 days or in the presence of circulating antibodies, which may persist for several years; hypersensitivity to benzyl alcohol (if only the multidose vial is available), enoxaparin, heparin (including low-molecular-weight heparins), pork products or their components

## Interactions

### DRUGS

*NSAIDs; oral anticoagulants; platelet aggregation inhibitors, such as aspirin, dipyridamole, salicylates, sulfinpyrazone, and ticlopidine; thrombolytics, such as alteplase, anistreplase, streptokinase, and urokinase:*  
Possibly increased risk of bleeding

# Adverse Reactions

**CNS:** Confusion, **CVA**, epidural or spinal hematoma, fever, headache, paralysis

**CV:** **Atrial fibrillation**, **congestive heart failure**, hyperlipidemia, peripheral edema, **thrombosis**

**EENT:** Epistaxis

**GI:** Bloody stools, **cholestatic and hepatocellular liver injury**, diarrhea, elevated liver enzymes, **hematemesis**, **melena**, nausea, vomiting

**GU:** Hematuria, menstrual irregularities

**HEME:** Anemia, eosinophilia, **hemorrhage**, **HIT or immune-mediated thrombocytopenia**, **purpura**, **thrombocytopenia**, purpura, thrombocytopenia, thrombocytosis

**MS:** Osteoporosis (with long-term therapy)

**RESP:** Dyspnea, pneumonia, **pulmonary edema**, or **embolism**

**SKIN:** Alopecia, cutaneous vasculitis, ecchymosis, persistent bleeding or oozing from mucous membranes or surgical wounds, pruritus, skin necrosis at injection site or distant from injection site, urticaria, vesiculobullous rash

**Other:** **Anaphylaxis including shock**; **hyperkalemia**; injection-site erythema, hematoma, inflammation, irritation, nodules, oozing, and pain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.

- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Be aware that all patients receiving anticoagulants, including pregnant women, are at risk for bleeding.
- Know that the multiple-dose vial of the drug contains 15 mg benzyl alcohol per 1 ml as a preservative. Cases of gasping syndrome have occurred in premature infants when large amounts of benzyl alcohol have been administered (99 to 405 mg/kg/day) to the mother.

## **LABOR & DELIVERY**

- Be aware that drug therapy may be changed to a shorter acting anticoagulant as delivery approaches to decrease bleeding risk for both mother and fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Use enoxaparin with extreme caution in patients with a history of heparin-induced thrombocytopenia (HIT). Know that enoxaparin should only be used in these patients if more than 100 days have elapsed since the prior HIT episode and no circulating antibodies are present.
- Use also extreme caution in patients with an increased risk of hemorrhage, as from active ulcerative or angiodysplastic GI disease; bacterial endocarditis; congenital or acquired bleeding disorder; concurrent treatment with a platelet inhibitor; hemorrhagic stroke; or recent brain, ophthalmologic, or spinal surgery.
- Use cautiously in those with bleeding diathesis, diabetic retinopathy, hepatic or renal impairment, recent GI hemorrhage or ulceration, or uncontrolled hypertension. Expect delayed elimination in elderly patients and those with renal insufficiency.
- Be aware that drug isn't recommended for patients with prosthetic heart valves, especially pregnant women, because of risk of prosthetic valve

thrombosis. If enoxaparin is needed, monitor peak and trough antifactor Xa levels often and adjust dosage as needed.

- Know that use of multidose vials should be avoided if at all possible in pregnant women because benzyl alcohol may cross the placenta and cause fetal harm.
- Don't give drug by I.M. injection.

**WARNING** Know that if patient is receiving enoxaparin with epidural or spinal anesthesia or spinal puncture, watch closely for development of spinal hematoma, which may cause long-term or permanent paralysis. If evidence of neurologic impairment, such as changes in sensory or motor function, occurs, notify prescriber immediately because urgent care is needed to minimize hematoma's effect. Risk of epidural or spinal hematoma during enoxaparin therapy is increased by indwelling epidural catheters, concurrent use of other drugs that affect hemostasis, a history of traumatic or repeated epidural or spinal punctures, or a history of spinal deformity or spinal surgery. Know that placement or removal of a catheter should be delayed for at least 12 hours after administration of lower doses of enoxaparin (30 mg once or twice daily or 40 mg once daily) and at least 24 hours after the administration of higher doses. (0.75 mg/kg twice daily, 1 mg/kg twice daily, or 1.5 mg/kg once daily). However, for patients with creatinine clearance of less than 30 ml/min, timing of removal should be doubled because enoxaparin elimination is more prolonged in renal dysfunction.

- Expect to give drug with aspirin to patient with unstable angina, STEMI, and non-Q-wave MI. To minimize risk of bleeding after vascular procedures, give enoxaparin at recommended intervals.
- Know that after a percutaneous revascularization procedure, it is important to achieve hemostasis at the puncture site. A closure device may be removed right away; however, if a manual compression method is used, the sheath should be removed 6 hours after last enoxaparin dose. If

enoxaparin therapy will continue, give next scheduled dose no sooner than 6 to 8 hours after sheath removal.

- Watch closely for bleeding. Notify prescriber immediately if platelet count falls below  $100,000/\text{mm}^3$ . Expect to stop drug and start treatment if patient has a thromboembolic event, such as a stroke.
- Test stool for occult blood, as ordered.
- Keep protamine sulfate nearby in case of accidental overdose.
- Check serum potassium level for elevation, especially in patients with renal impairment or who are currently using potassium-sparing diuretics.

## **PATIENT TEACHING**

- Advise patient to notify prescriber about adverse reactions, especially bleeding. Inform patient that taking aspirin or other NSAIDs may increase risk for bleeding.
- Instruct patient to seek immediate help for evidence of thromboembolism, such as neurologic changes and severe shortness of breath. Also tell patient to report any unusual bleeding, bruising, or rash of dark red spots under the skin to prescriber.
- Emphasize the importance of complying with follow-up visits with prescriber.
- Teach patient or family member how to give enoxaparin at home, if needed. Show how to give drug by deep subcutaneous injection while lying down. Instruct him not to expel air bubble from a prefilled syringe to avoid losing some of the drug. Tell him to insert the entire needle into a skin fold held between the thumb and forefinger. Remind him to alternate injection sites between the left and right anterolateral abdominal wall.
- Caution patient not to rub the site after giving the injection to minimize bruising.
- Review safe handling and disposal of syringes and needles.
- Instruct patient to alert all healthcare providers, but especially those administering anesthesia, about enoxaparin therapy. If neuraxial anesthesia or spinal puncture is necessary, and especially if taking other drugs that could affect bleeding, tell patient to watch for signs and symptoms of epidural or spinal bleeding such as muscle weakness or numbness or tingling in lower extremities.
- Inform patient that he may bruise and/or bleed more easily and that it may take longer than usual to stop bleeding while taking enoxaparin.

Review bleeding precautions with patient.

# entecavir

## Baraclude

### Class and Category

*Pharmacologic class:* Nucleoside analogue

*Therapeutic class:* Antiviral

### Indications and Dosages

- *To treat chronic hepatitis B virus infection in patients with evidence of active viral replication and either evidence of persistent elevations in serum aminotransferases (ALT or AST) or histologically active disease*

### ORAL SOLUTION, TABLETS

**Adults and adolescents ages 16 and over if treatment-naive with compensated liver disease.** 0.5 mg once daily 2 hr before or after a meal.

**Adults and adolescents ages 16 and over who have a history of hepatitis B viremia while receiving lamivudine or have experienced known lamivudine or telbivudine resistance substitutions; adults with compensated liver disease.** 1 mg once daily 2 hr before or after a meal.

**Adults with decompensated liver disease.** 1 mg once daily 2 hr before or after a meal.

**Children ages 2 and over weighing more than 30 kg (66 lb).** 0.5 mg (10 ml oral solution) once daily if treatment-naïve or 1 mg (20-ml oral solution) once daily if lamivudine-experienced, 2 hr before or after a meal.

**Children ages 2 and over weighing more than 26 kg (57.2 lb) but less than 30 kg (66 lb).** 9 ml oral solution once daily if treatment-naïve or 18 ml oral solution once daily if lamivudine-experienced, 2 hr before or after a meal.

**Children ages 2 and over weighing more than 23 kg (50.6 lb) but less than 26 kg (57.2 lb).** 8 ml oral solution once daily if treatment-naïve or 16 ml oral solution once daily if lamivudine-experienced, 2 hr before or after a meal.

**Children ages 2 and over weighing more than 20 kg (44 lb) but less than 23 kg (50.6 lb).** 7 ml oral solution once daily if treatment-naïve or 14 ml oral solution once daily if lamivudine-experienced, 2 hr before or after a meal.

**Children ages 2 and over weighing more than 17 kg (37.4 lb) but less than 20 kg (44 lb).** 6 ml oral solution once daily if treatment-naïve or 12 ml oral solution once daily if lamivudine-experienced, 2 hr before or after a meal.

**Children ages 2 and over weighing more than 14 kg (30.8 lb) but less than 17 kg (37.4 lb).** 5 ml oral solution once daily if treatment-naïve or 10 ml oral solution once daily if lamivudine-experienced, 2 hr before or after a meal.

**Children ages 2 and over weighing more than 11 kg (24.2 lb) but less than 14 kg (30.8 lb).** 4 ml oral solution once daily if treatment-naïve or 8 ml oral solution

once daily if lamivudine-experienced, 2 hr before or after a meal.

**Children ages 2 and over weighing at least 10 kg (22 lb) but less than 11 kg (24.2 lb).** 3 ml oral solution once daily if treatment-naïve or 6 ml oral solution once daily if lamivudine-experienced, 2 hr before or after a meal.

**DOSAGE ADJUSTMENT** For adult patient with a creatinine clearance between 30 and less than 50 ml/min, dosage reduced to 0.25 mg once daily or 0.5 mg every 48 hr if treatment-naïve, and dosage reduced to 0.5 mg once daily or 1 mg every 48 hr if lamivudine-refractory or decompensated liver disease is present. For adult patient with a creatinine clearance between 10 and less than 30 ml/min, dosage reduced to 0.15 mg once daily or 0.5 mg every 72 hr if treatment-naïve, and dosage reduced to 0.3 mg once daily or 1 mg every 72 hr if lamivudine-refractory or decompensated liver disease is present. For adult patient with a creatinine clearance less than 10 ml/min or who is on dialysis, dosage reduced to 0.05 mg once daily or 0.5 mg every 7 days (given after hemodialysis) if treatment-naïve, and dosage reduced to 0.1 mg once daily or 1 mg every 7 days (given after hemodialysis) if lamivudine-refractory or decompensated liver disease is present. For pediatric patients with renal impairment, there is insufficient data to recommend a specific dose adjustment but a reduction in dose and/or an increase in dosing interval similar to adults may be considered.

## **Mechanism of Action**

Inhibits all three activities of the hepatitis B virus (HBV) reverse transcriptase which are base priming, reverse transcription of the negative strand from the pregenomic messenger RNA, and synthesis of the positive strand of

HBV DNA. This lowers the ability of HBV to multiply and infect new liver cells.

## Contraindications

Hypersensitivity to entecavir or its components

## Interactions

### DRUGS

*drugs that reduce renal function or compete for active tubular secretion:* Possibly increased serum concentrations of either entecavir or the coadministered drug, increasing risk of adverse reactions

## Adverse Reactions

**CNS:** Dizziness, fatigue, fever, headache, **hepatic encephalopathy**, insomnia, somnolence

**CV:** Peripheral edema

**EENT:** Taste abnormality

**ENDO:** Hyperglycemia

**GI:** Abdominal pain, ascites, diarrhea, dyspepsia, elevated liver and pancreatic enzymes, **exacerbation of hepatitis** (after discontinuation of therapy), **gastrointestinal hemorrhage**, **hepatic failure**, **hepatorenal syndrome**, hyperalbuminemia, hyperbilirubinemia, nausea, **severe hepatomegaly with steatosis**, vomiting

**GU:** Elevated creatinine level, glycosuria, hematuria, **renal failure**

**HEME:** **Decreased platelet count**

**RESP:** Upper respiratory infection

**SKIN:** Alopecia, rash

**Other:** Anaphylaxis, decreased serum bicarbonate level, lactic acidosis

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Ensure that patient has been tested for HIV infection before entecavir therapy begins, because resistance to HIV therapy may develop when entecavir is administered to treat chronic hepatitis B virus infection in patients who also have an HIV infection that is not being treated. Know that entecavir therapy is not recommended for co-infected patients who are not receiving treatment.

**WARNING** Know that lactic acidosis and severe hepatomegaly with steatosis have occurred with entecavir therapy and death has occurred in some patients. Risk factors include the presence of obesity, prolonged nucleoside exposure, and being a woman. However, know that lactic acidosis and severe hepatomegaly with steatosis

have also occurred in patients with no known risk factors. Monitor patient's liver enzymes as ordered. Expect entecavir to be discontinued in any patient who develops clinical or laboratory findings suggestive of lactic acidosis or pronounced hepatotoxicity, even in the absence of marked transaminase elevations.

- Expect patient to be closely monitored for at least several months after entecavir has been discontinued, because severe acute exacerbation of hepatitis may occur.

## **PATIENT TEACHING**

- Instruct patient with hepatitis B on the importance of testing for HIV before therapy begins and then periodically throughout therapy to avoid development of resistance to HIV treatment.
- Instruct patient to take entecavir once daily on an empty stomach either 2 hours before a meal or 2 hours after a meal.
- Tell patient that entecavir therapy does not reduce the transmission of HBV to others through blood contamination or sexual contact.
- If patient misses a dose, tell him to take it as soon as he remembers but not to double the next dose or take more than the prescribed dose.
- Instruct patient using the oral solution to hold the dosing spoon in a vertical position and fill it gradually to the mark corresponding to the prescribed dose. The dosing spoon should be rinsed after each daily dose.
- Warn patient with hepatitis B that acute severe exacerbations of hepatitis B may occur following discontinuation of entecavir. He should not discontinue drug without prescriber knowledge. Tell patient to report any reappearance of signs and symptoms of hepatitis B.
- Instruct mothers not to breastfeed while receiving entecavir therapy, as drug is present in human breast milk.
- Advise female patient to notify prescriber if pregnancy occurs or is suspected. If pregnancy occurs, encourage patient to register with the Antiretroviral Pregnancy Registry at 1-800-258-4263.

**WARNING** Alert patient that severe conditions may develop while taking entecavir. Encourage him to stop taking

drug and seek medical attention immediately if he experiences any persistent, severe, or unusual symptoms.

## epinephrine

(adrenaline)

**Adrenalin, Auvi-Q, EpiPen, EpiPen Jr., Symjepi**

### Class and Category

*Pharmacologic class:* Sympathomimetic

*Therapeutic class:* Antianaphylactic, bronchodilator, cardiac stimulant, vasopressor

### Indications and Dosages

➤ *To treat anaphylaxis*

#### **I.M. OR SUBCUTANEOUS INJECTION**

**Adults and children weighing 30 kg (66 lb) or more.**

0.3 to 0.5 mg, repeated every 5 to 10 min, as needed.

**Children weighing less than 30 kg (66 lb).** 0.01 mg/kg up to maximum of 0.3 mg per injection, repeated every 5 to 10 min, as needed.

➤ *To provide emergency treatment of allergic reactions (Type I), including anaphylaxis to allergen immunotherapy, biting and stinging insects, diagnostic*

*testing substances, drugs, foods, and other allergens,  
as well as exercise-induced or idiopathic anaphylaxis*

**Adults and children weighing 30 kg (66 lb) or more who are at increased risk for anaphylaxis.** 0.3 mg immediately upon exposure.

**Adults and children weighing 15 to 30 kg (33 to 66 lb) who are at increased risk of anaphylaxis.** 0.15 mg immediately upon exposure.

## **I.M. INJECTION, SUBCUTANEOUS INJECTION (AUVI-Q)**

**Children weighing 7.5 to 15 kg (16.5 to 33 lb) who are at increased risk of anaphylaxis.** 0.1 mg immediately upon exposure.

➤ *To treat hypotension associated with septic shock*

## **I.V. INFUSION**

**Adults.** 0.05 mcg/kg/min to 2 mcg/kg/min, titrated to achieve desired mean arterial pressure by adjusting dose every 10 to 15 min, in increments of 0.05 to 0.2 mcg/kg/min.

Route	Onset	Peak	Duration
I.M.	Rapid	Unknown	1-2 min
SubQ	5-10 min	In 20 min	Short
Oral inhalation	1-5 min	In 5-15 min	Up to 3 hr

## **Mechanism of Action**

Acts on alpha and beta receptors. This nonselective adrenergic agonist stimulates:

- $\alpha_1$  receptors, which constricts arteries and may decrease bronchial secretions
- presynaptic  $\alpha_2$  receptors, which inhibits norepinephrine release by way of negative feedback
- postsynaptic  $\alpha_2$  receptors, which constricts arteries
- $\beta_1$  receptors, which induces positive chronotropic and inotropic responses
- $\beta_2$  receptors, which dilates arteries, relaxes bronchial smooth muscles, increases glycogenolysis, and prevents mast cells from secreting histamine and other substances, thus reversing bronchoconstriction and edema.

## Incompatibilities

Don't mix epinephrine with alkalis or oxidizing agents, including bromine, chlorine, chromates, iodine, metal salts (as from iron), nitrites, oxygen, and permanganates, because these substances can destroy epinephrine.

## Contraindications

Cerebral arteriosclerosis, coronary insufficiency, dilated cardiomyopathy, general anesthesia with halogenated hydrocarbons or cyclopropane, hypersensitivity to epinephrine or its components, labor, angle-closure glaucoma, organic brain damage, shock (nonanaphylactic)

## Interactions

### DRUGS

*alpha blockers such as phentolamine, antihypertensives, diuretics, ergot alkaloids, phenothiazine antipsychotics, vasodilators such as nitrates:* Antagonized pressor effects of epinephrine

*antidepressants of the imipramine and triptyline types, MAO inhibitors: Increased risk of severe, prolonged hypertension*  
*antihistamines, beta blockers, cardiac glycosides, cyclopropane, diuretics, halogenated hydrocarbon anesthetics such as halothane, quinidine, thyroid hormones: Increased risk of cardiac arrhythmias*  
*beta blockers such as propranolol, catechol-O-methyl transferase (COMT) inhibitors such as entacapone, clonidine, doxapram, MAO inhibitors, oxytocin, sympathomimetics, tricyclic antidepressants: Potentiated pressor effects of epinephrine*  
*corticosteroids, potassium depleting diuretics, theophylline: Potentiated hypokalemic effects of epinephrine*

## **Adverse Reactions**

**CNS:** Anxiety, apprehensiveness, chills, **CVA**, disorientation, dizziness, drowsiness, excitability, fever, hallucinations, headache, impaired memory, insomnia, light-headedness, nervousness, panic, psychomotor agitation, restlessness, **seizures**, sleepiness, temporary worsening of Parkinson's disease, tingling, tremor, weakness

**CV: Arrhythmias, including ventricular fibrillation;** chest discomfort or pain; fast, irregular, or slow heartbeat; increased cardiac output; myocardial ischemia; palpitations; peripheral vasoconstriction; **severe hypertension; stress cardiomyopathy;** tachycardia; vasoconstriction; **ventricular ectopy**

**EENT:** Blurred vision, dry mouth or throat, miosis

**ENDO:** Hyperglycemia in diabetics

**GI:** Anorexia, heartburn, nausea, vomiting

**GU:** Dysuria, oliguria, renal impairment

**MS:** Muscle twitching, severe muscle spasms

**RESP:** Dyspnea, **pulmonary edema**

**SKIN:** Cold skin, diaphoresis, ecchymosis, flushed or red face or skin, pallor, tissue necrosis

**Other:** **Hyperkalemia**; **hypokalemia**; injection-site coldness, hypoesthesia, infections (*Clostridia*), pain, pallor, and stinging

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- May delay second stage of labor because drug usually inhibits spontaneous or oxytocin induced contractions. It may also cause a prolonged period of uterine atony with hemorrhage.
- Drug should be avoided during second stage of labor and in patients with a blood pressure that exceeds 130/80 mm/Hg.
- While drug may improve maternal hypotension associated with anaphylaxis and septic shock, it may cause decreased uterine blood flow, fetal anoxia, and uterine vasoconstriction.

### LACTATION

- It is not known if drug is present in breast milk.

- Patient should check with prescriber before breastfeeding after receiving epinephrine.

## Nursing Considerations

- Use epinephrine with extreme caution in patients with angina, arrhythmias, asthma, degenerative heart disease, or emphysema. Epinephrine's inotropic effect equals that of dopamine and dobutamine; its chronotropic effect exceeds that of both.
- Use drug cautiously in elderly patients and those with cardiovascular disease (other than listed above), diabetes mellitus, hypertension, hyperthyroidism, prostatic hypertrophy, and psychoneurologic disorders.
- Know that if the Adrenalin brand of epinephrine is used during intraocular surgery to induce and maintain mydriasis, the 30-ml multiple-dose vial of the drug should not be used because it contains chlorobutanol, which may be harmful to the corneal endothelium. Also, be aware that the Adrenalin 1-ml single-use vial must be diluted before intraocular use.
- Be aware that some preparations contain sulfites, which may cause allergic-type reactions. However, the presence of sulfites in epinephrine should not deter its use in a patient with anaphylaxis, even if patient is sensitive to sulfites. Monitor patient closely for adverse effects.
- Be aware that the brands, Auvi-Q and Symjepi, are intended for use as emergency supportive therapy only and are not a substitute for immediate medical care.
- Inspect epinephrine solution before use. If it's pink or brown, air has entered a multidose vial. If it's discolored or contains particles, discard it. Also discard unused portions of parenteral epinephrine.
- Prepare epinephrine for I.V. infusion by diluting 1 mg of epinephrine to 1,000 ml of a 5 percent dextrose or 5 percent dextrose and sodium chloride solution to produce a 1 mcg/ml dilution. Know that administration in saline solution alone is not recommended. When possible, administer I.V. infusion into a large vein. Avoid using a catheter tie-in technique, because the obstruction to blood flow around the tubing may cause stasis and increased local concentration of the drug. Avoid the veins of the leg in elderly patients or in those suffering from occlusive vascular diseases. Once epinephrine is diluted, the solution is stable for 4 hours at room temperature or 24 hours under refrigerated conditions.
- Avoid extravasation of epinephrine into the tissues to prevent local necrosis. Assess infusion site frequently for free flow and look for blanching along the course of the infused vein which may indicate some

leakage from the vein wall. If blanching occurs, change infusion site. To prevent sloughing and necrosis in areas in which extravasation has taken place, obtain an order to infiltrate the area with 10 to 15 ml of saline solution containing 5 to 10 mg phentolamine. Using a syringe with a fine hypodermic needle infiltrate the area liberally, which is easily identified by its cold, hard, and pallid appearance

- For injection, inject the drug into the anterolateral aspect of the thigh. Do not use the deltoid muscle or inject into the buttocks because absorption may not be the same. When administering drug to a child, hold the leg firmly in place and limit movement prior to and during an injection to minimize the risk of injury related to the injection, especially if drug was inadvertently injected into buttock.
- Remember to rotate sites because repeated injections in the same site may cause vasoconstriction and localized necrosis.
- Assess injection site periodically after administration of epinephrine for signs of infection such as persistent redness, swelling, tenderness, or warmth. Report any findings immediately to prescriber because, although rare, serious skin and soft-tissue infections, including myonecrosis and necrotizing fascitis caused by *Clostridia* (gas gangrene), have been reported at the injection site following epinephrine injection, especially if drug was inadvertently injected into buttock.
- Be aware that drug shouldn't be given by intra-arterial injection because marked vasoconstriction may cause gangrene. Also know that accidental injection of the drug into the patient's feet, fingers, or hands may result in loss of blood flow to the affected area.

**WARNING** Know that clostridial infections (gas gangrene) have occurred when administered in the buttocks. Know that cleansing the site with alcohol does not kill bacterial spores and therefore does not lower this risk. Also, the drug may be less effective when given there, especially for treating anaphylaxis. Therefore, avoid injecting epinephrine into the buttocks.

- Monitor patient's blood pressure frequently and titrate I.V. dosages to avoid excessive increases in blood pressure.
- Monitor patient for cardiac arrhythmias and myocardial ischemia, especially patients suffering from cardiomyopathy or coronary artery disease.

- Monitor patient for potassium imbalances. Initially, hyperkalemia occurs when hepatocytes release potassium. Hypokalemia may quickly follow as skeletal muscles take up potassium.

## PATIENT TEACHING

- Teach patient how to use oral inhaler or inhalation solution, as needed.
- Instruct patient using an oral corticosteroid inhaler to use epinephrine inhaler first, wait for 5 minutes, and then use corticosteroid inhaler to increase effectiveness.
- Teach patient and family how to administer epinephrine subcutaneously in an emergency. Tell them to inject drug only into anterolateral aspect of the thigh, through the clothing if necessary. If injecting drug into a child, stress importance of holding the leg firmly in place and limiting movement prior to and during the injection, to prevent injury. Tell them to inspect the site for signs of infection afterward and report if persistent redness, swelling, tenderness, and warmth develop.

**WARNING** Instruct patient and family never to give epinephrine in the buttocks, as absorption may be hindered. Also, a serious infection (gas gangrene) may occur if injected in the buttocks. In addition, tell patient and family to inspect the thigh for signs of infection at the injection site and report if persistent redness, swelling, tenderness, and warmth develop.

- Remind patient or family using the brands Auvi-Q or Symjepi that drug is intended for emergency supportive therapy only. Stress importance of seeking immediate care after drug is administered.
- Explain that solution is light sensitive and should be stored in the carrying case and at room temperature. Tell them not to refrigerate drug and to replace solution if it discolors.
- Caution patient to avoid accidental injecting drug into his fingers, hands, toes, or feet because epinephrine is a strong vasoconstrictor and could cause loss of blood flow to the area, resulting in gangrene. If accidental injection occurs in any of these areas, instruct patient to go immediately to nearest emergency room.
- Advise patient to notify prescriber immediately if he has blurred vision, chest pain, fast or irregular heartbeat, increased sweating, or trouble

breathing.

- Inform patient with diabetes that epinephrine may cause hyperglycemia. Inform patient with Parkinson's disease that symptoms may temporarily worsen but this should not deter use of drug.

## eplerenone

**Inspira**

### Class and Category

*Pharmacologic class:* Aldosterone receptor blocker

*Therapeutic class:* Antihypertensive

### Indications and Dosages

- *To improve survival of stable patients with symptomatic heart failure with reduced ejection fraction (equal to or less than 40%) after an acute myocardial infarction*

#### **TABLETS**

**Adults.** *Initial:* 25 mg daily, increased to 50 mg daily within 4 wk, as needed. Then dosage adjusted based on the serum potassium level.

***DOSAGE ADJUSTMENT*** Dosage adjusted based on the serum potassium level. If potassium level is less than 5.0 mEq/L and patient is taking 25 mg every other day, dosage interval increased to daily; if patient is taking 25 mg once daily, dosage increased to 50 mg once. daily. If potassium level is 5.0 to 5.4 mEq/L, no adjustment needed. If

potassium level is between 5.5 and 5.9 mEq/L and patient is taking 50 mg once daily, dosage reduced to 25 mg once daily, or if patient is taking 25 mg once daily, dosage interval increased to 25 mg every other day; if already taking 25 mg every other day or potassium level is 6.0 mEq/L or higher, drug withheld until potassium level returns to acceptable level. Dosage then restarted at 25 mg every other day.

➤ *To treat hypertension alone or with other antihypertensive drugs*

## TABLETS

**Adults.** *Initial:* 50 mg daily, increased to 50 mg twice daily after 4 wk, if needed.

***DOSAGE ADJUSTMENT*** For patients taking moderate CYP450 3A4 inhibitors, such as erythromycin, fluconazole, saquinavir, and verapamil, initial dosage for hypertension reduced to 25 mg daily. If patient's blood pressure is not controlled with this dose, dosing increased to maximum of 25 mg twice daily. For post-MI congestive heart failure patient, maximum dosage is 25 mg once daily.

## Mechanism of Action

Blocks the binding of aldosterone at its mineralocorticoid receptor sites located in the blood vessels, brain, heart, and kidneys. This action decreases blood pressure by preventing aldosterone from inducing sodium reabsorption and possibly other mechanisms that contribute to raising blood pressure.

## Contraindications

*For all patients:* Concurrent therapy with strong CYP3A inhibitors, creatinine clearance 30 ml/min or less, hyperkalemia (greater than 5.5 mEq) at initiation, hypersensitivity to eplerenone or its components

*For patients with hypertension:* Concurrent therapy with potassium supplements or potassium-sparing diuretics, creatinine level greater than 2 mg/dl in males and greater than 1.8 mg/dl in females, creatinine clearance less than 50 ml/min, type 2 diabetes mellitus with microalbuminuria

## Interactions

### DRUGS

*ACE inhibitors, angiotensin II receptor antagonists:*

Increased risk of hyperkalemia

*CYP3A inhibitors:* Increased blood level and effect of eplerenone

*lithium:* Possibly lithium toxicity

*NSAIDs:* Possibly reduced antihypertensive effect of eplerenone; severe hyperkalemia in patients with impaired renal function

## Adverse Reactions

**CNS:** Dizziness, fatigue, headache

**CV:** Angina pectoris, hypercholesterolemia, hypertriglyceridemia, **MI**

**ENDO:** Gynecomastia, mastodynia

**GI:** Abdominal pain, diarrhea, increased liver enzymes

**GU:** Albuminuria, elevated BUN and serum creatinine levels, vaginal bleeding

**RESP:** Cough

**Other:** Flu-like symptoms, **hyperkalemia**, **hyponatremia**, increased uric acid level

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### REPRODUCTION

- Male fertility may become compromised with drug therapy based on animal studies.

## Nursing Considerations

- Monitor patient's blood pressure regularly to evaluate eplerenone effectiveness.
- Be aware that patients with diabetes, impaired renal function, or proteinuria or who take an ACE inhibitor or an angiotensin II receptor antagonist during eplerenone therapy have an increased risk of hyperkalemia.
- Monitor patient's serum potassium level every 2 weeks for the first month or two of therapy until the effects of eplerenone are known and monthly thereafter, as ordered. Notify prescriber of abnormalities, as dosage will need to be adjusted.
- Monitor patients over 65 closely, because the risk of hyperkalemia may be increased because of age-related decreases in creatine clearance.

## PATIENT TEACHING

- Caution patient not to use potassium salt substitutes or potassium-containing supplements because increased potassium levels can lead to serious adverse reactions to eplerenone.
- Urge patient to tell all prescribers about eplerenone use because of possible interactions.

### epoetin alfa

(EPO, erythropoietin alfa, recombinant erythropoietin, r-HuEPO)

**Epogen, Eprex (CAN), Procrit**

**epoetin alfa-epbx**

**Retacrit**

## Class and Category

*Pharmacologic class:* Erythropoietin

*Therapeutic class:* Antianemic

## Indications and Dosages

➤ *To treat anemia due to chronic kidney disease*

## I.V. OR SUBCUTANEOUS INJECTION

**Adults on dialysis but not hemodialysis and hemoglobin is less than 10 g/dl.**

*Initial:* 50 to 100 units/kg 3 times/wk, increased as needed by 25% at 4-wk intervals or longer. *Maintenance:* Dosage highly individualized to lowest dose that keeps hemoglobin below 11 g/dl.

**Neonates age 1 month and older and children on dialysis when hemoglobin is less than 10 g/dl.** 50 units/kg 3 times/wk; increased as needed by 25% at 4-wk intervals or longer. *Maintenance:* Dosage highly individualized to lowest dose that keeps hemoglobin below 12 g/dl.

## **I.V. INJECTION**

**Adults on hemodialysis and hemoglobin is less than 10 g/dl.** *Initial:* 50 to 100 units/kg 3 times/wk, increased as needed by 25% at 4-wk intervals or longer. *Maintenance:* Dosage highly individualized to lowest dose that keeps hemoglobin below 11 g/dl.

## **I.V. OR SUBCUTANEOUS INJECTION**

**Adults not on dialysis with hemoglobin less than 10 g/dl, and the rate of hemoglobin decline indicates the likelihood of requiring a RBC transfusion and reducing the risk of alloimmunization and/or other RBC transfusion-related risks is a goal.** *Initial:* 50 to 100 units/kg 3 times/wk, *Maintenance:* Dosage highly individualized to lowest dose that keeps hemoglobin below 10 g/dl.

**Neonates age 1 month and older and children not on dialysis.** 50 units/kg 3 times/wk; increased as needed by 25% at 4-wk intervals or longer. *Maintenance:* Dosage highly individualized to lowest dose that keeps hemoglobin below 12 g/dl.

**DOSAGE ADJUSTMENT** For patients with anemia from renal failure on dialysis, dosage temporarily reduced or drug discontinued if hemoglobin approaches or exceeds 11 g/dl (12 g/dl for children). For patients with anemia from renal failure not on dialysis, dosage temporarily reduced or drug discontinued if hemoglobin exceeds 10 g/dl (12 g/dl for children). For patients with anemia from renal failure with or without dialysis, dosage reduced 25% or more if hemoglobin rises rapidly (more than 1 g/dl in any 2-week period).

- *To treat anemia in HIV-infected patients who take zidovudine*

## **I.V. OR SUBCUTANEOUS INJECTION**

**Adults with serum erythropoietin level of 500 mU/ml or less who receive 4,200 mg or less of zidovudine/wk.**

*Initial:* 100 units/kg 3 times/wk, increased by 50 to 100 units/kg every 4 to 8 wk after 8 wk of therapy.

*Maintenance:* Dosage gradually titrated to maintain desired response, based on such factors as variations in zidovudine dosage and occurrence of infection or inflammation. If hemoglobin exceeds 12 g/dl, drug withheld and resumed at a dose 25% below the previous dose when hemoglobin has declined to less than 11 g/dl. *Maximum:* 300 units/kg 3 times/wk or hemoglobin has reached a level needed to avoid RBC transfusions.

- *To treat anemia from chemotherapy*

## **SUBCUTANEOUS INJECTION**

**Adults with a hemoglobin less than 10 g/dl, and there is a minimum of two additional months of planned chemotherapy.**

*Initial:* 150 units/kg 3 times/wk or 40,000 units weekly until completion of a chemotherapy course.

Dosage decreased by 25% if hemoglobin level approaches a

level needed to avoid RBC transfusion or increases more than 1 g/dl in any 2-wk period. Dose withheld if hemoglobin exceeds a level needed to avoid RBC transfusion and resumed at 25% less than previous dose when hemoglobin approaches a level where RBC transfusions may be required. Dosage increased to 300 units/kg 3 times/wk or 60,000 units weekly after 4 wk if response is inadequate. *Maximum:* 300 units/kg 3 times/wk; or 60,000 units weekly.

## **I.V. INJECTION**

**Children ages 5 to 18 with a hemoglobin less than 10 g/dl, and if there is a minimum of two additional months of planned chemotherapy.** 600 units/kg until completion of a chemotherapy course. Dosage decreased by 25% if hemoglobin level approaches a level needed to avoid RBC transfusion or increases more than 1 g/dl in any 2-wk period. Dose withheld if hemoglobin exceeds a level needed to avoid RBC transfusion, then dose reinitiated at a dose 25% below the previous dose when hemoglobin approaches a level where RBC transfusions may be required. Dosage increased to 900 units/kg weekly after initial 4 wk of therapy if hemoglobin increases by less than 1 g/dl and remains below 10 g/dl. *Maximum:* 60,000 units weekly.

- *To reduce need for allogeneic red blood cell transfusions in patients undergoing elective, noncardiac, nonvascular surgery*

## **SUBCUTANEOUS INJECTION**

**Adults.** 300 units/kg daily for 10 days before surgery, on day of surgery, and 4 days after surgery; or 600 units/kg/wk on 21, 14, and 7 days before surgery and on the day of surgery. Dose of 300 units/kg repeated on day of surgery.

Route	Onset	Peak	Duration
I.V., SubQ	In 2–6 wk	In 2 mo	About 2 wk

## Mechanism of Action

Stimulates the release of reticulocytes from the bone marrow into the bloodstream, where they develop into mature RBCs.

## Incompatibilities

Don't mix epoetin alfa with any other drug.

## Contraindications

Hypersensitivity to epoetin alfa, epoetin alfa-epbx, or its components; pure red cell aplasia that began after treatment with epoetin alfa, epoetin alfa-epbx, or other erythropoietin protein drugs; uncontrolled hypertension; use of multidose vials in infants, neonates, or women who are breastfeeding or pregnant

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Anxiety, asthenia, **CVA**, dizziness, fatigue, fever, headache, insomnia, paresthesia, **seizures**

**CV:** Chest pain, **congestive heart failure**, **deep vein thrombosis**, edema, hypertension, **MI**, tachycardia,

## thromboembolic events

**GI:** Constipation, diarrhea, indigestion, nausea, vomiting

**GU:** UTI

**HEME:** Polycythemia

**MS:** Arthralgia, bone pain, muscle weakness

**RESP:** Cough, dyspnea, **pulmonary congestion**, upper respiratory tract infection

**SKIN:** **Erythema multiforme**, rash, pruritus, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** Flu-like symptoms, **hyperkalemia**, injection-site reaction, trunk pain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Be aware that the multiple-dose vials of the drug contain benzyl alcohol, which may cause serious and even life-threatening adverse reactions in the fetus and neonate.
- Know that use of the multiple-dose vials of the drug are contraindicated for use in pregnant women. A benzyl alcohol-free formulation should be used instead such as the single-dose vial.
- Do not mix drug with bacteriostatic saline containing benzyl alcohol when administering to pregnant women.

### LACTATION

- It is not known if drug is present in breast milk.

- Advise patient to check with prescriber before breastfeeding if drug will be administered from a single-dose vial.
- Use of the multiple-dose vial of the drug is contraindicated in women who are breastfeeding.
- Do not mix drug with bacteristatic saline containing benzyl alcohol being administering to a woman who is breastfeeding.
- Inform breastfeeding women that if drug is administered using a multiple-dose vial, breastfeeding should be withheld for at least 2 weeks after the last dose.

## Nursing Considerations

- Be aware that epoetin alfa shouldn't be given to cancer patients when a cure is anticipated because drug may decrease survival rate and increase tumor progression in patients with certain types of cancers, such as breast, non-small-cell lung, head and neck, lymphoid, and cervical cancers. All prescribers and hospitals must enroll and comply with the ESA APPRISE Oncology program to be able to prescribe and dispense the drug.
- Ensure that patient has received the medication guide and patient instructions for epoetin alfa and that a written acknowledgment of a discussion of the risks involved with this type of therapy has been obtained before first dose is given.
- Evaluate the patient's serum iron level before and during treatment, as ordered. Expect to give an iron supplement (I.V. iron dextran, if needed) because iron requirements rise when erythropoiesis consumes existing iron stores.
- Use epoetin alfa cautiously in patients who have conditions that could decrease or delay response to drug, such as aluminum intoxication, folic acid deficiency, hemolysis, infection, inflammation, iron deficiency, malignant neoplasm, osteitis (fibrosa cystica), or vitamin B<sub>12</sub> deficiency.
- Also use drug cautiously in patients with cardiovascular disorders caused by hypertension, a history of porphyria or seizures, vascular disease, or a hematologic disorder, such as hypercoagulation, myelodysplastic syndrome, or sickle cell disease.

**WARNING** Be aware that the multidose vial of epoetin contains benzyl alcohol, which can cause a fatal toxic syndrome in neonates and immature infants

characterized by circulatory, CNS, renal, and respiratory impairment and metabolic acidosis. Know that use of multidose vial is contraindicated in infants and neonates and during pregnancy.

- Use lowest possible dose in cancer patients because drug has shortened survival rate and increased tumor progression in patients with certain types of cancers, such as breast, non-small-cell lung, head and neck, and lymphoid cancers. Drug should only be used to treat anemia caused by myelosuppressive chemotherapy in cancer patients.
- Don't shake vial while preparing to avoid denaturing glycoprotein, inactivating drug.
- Discard unused portion of single-dose vial because it contains no preservatives. Discard unused portion of multidose vial after 21 days.
- Be aware that baseline hemoglobin level should be above 10 but below 13 g/dl if drug is given to patient scheduled for surgery. Watch closely throughout surgical period for deep vein thrombosis, especially in patients not receiving prophylactic anticoagulation, because risk increases.
- Evaluate the patient's serum iron level before and during treatment, as ordered. Expect to give an iron supplement (I.V. iron formulation, if needed) because iron requirements rise when erythropoiesis consumes existing iron stores.
- Check hemoglobin levels, as ordered, with twice-weekly measurements recommended for chronic renal failure patients, until stable and then monthly thereafter and weekly measurements recommended for zidovudine-treated HIV-infected and cancer patients.

**WARNING** Know that hemoglobin shouldn't exceed 11 g/dl when treating anemia in patients with chronic renal failure on dialysis and 10 g/dl for patients not on dialysis. Exceeding these parameters increases risk of life-threatening adverse cardiovascular effects.

- Expect to increase heparin dose if patient receives hemodialysis because epoetin alfa can increase the RBC volume, which could cause clots to form in the dialyzer, hemodialysis vascular access, or both.
- Monitor patient for hypertensive or thrombotic complications, especially if hemoglobin is approaching target goal.

- Monitor patient throughout therapy for skin reactions which may include blistering and skin exfoliation that could be severe. If present, notify prescriber at once and expect drug to be discontinued.

## PATIENT TEACHING

- Ensure that patient has been instructed on the serious adverse effects related to epoetin alfa therapy before therapy begins.
- Teach patient how to administer drug and how to dispose of needles properly. Caution him against reusing needles.
- Emphasize the importance of complying with the dosage regimen and keeping follow-up medical appointments and appointments for laboratory tests.
- Encourage patient to eat iron-rich foods.
- Review possible adverse reactions, and urge patient to notify prescriber if he experiences chest pain, headache, hives, rapid heartbeat, rash, seizures, shortness of breath, or swelling. Also inform patient of the possibility of severe skin reactions such as blistering and exfoliation. Stress importance of stopping drug and alerting prescriber immediately if present.
- Advise women of childbearing age to use effective contraception during therapy if pregnancy isn't desired because menses may resume after epoetin alfa therapy.

**eptifibatide**

**Integrilin**

## Class and Category

*Pharmacologic class:* Glycoprotein IIb/IIIa inhibitor

*Therapeutic class:* Antiplatelet

# Indications and Dosages

- *To treat acute coronary syndrome (unstable angina and non-ST-elevation MI)*

## I.V. INFUSION, I.V. INJECTION

**Adults.** *Initial:* 180 mcg/kg over 1 to 2 min as soon as possible after diagnosis, followed by 2 mcg/kg/min by continuous infusion immediately after initial dose and continuing until discharge or coronary artery bypass grafting (CABG), up to 72 hr. If patient is to undergo PCI, infusion continued until hospital discharge or for up to 18 to 24 hr after the procedure, whichever comes first, allowing for up to 96 hr of therapy.

**DOSAGE ADJUSTMENT** For patient with serum creatinine level less than 50 ml/min, initial bolus remains unchanged at 180 mcg/kg but continuous infusion decreased to 1.0 mcg/kg/min.

- *To treat patients undergoing percutaneous transluminal coronary angioplasty (PTCA), including intracoronary stenting*

## I.V. INFUSION, I.V. INJECTION

**Adults.** *Initial:* 180 mcg/kg over 1 to 2 min immediately before procedure, immediately followed by a continuous infusion of 2 mcg/kg/min, and a second 180 mcg/kg bolus administered 10 minutes after the first. The continuous infusion continued until hospital discharge, or for up to 18 to 24 hr, whichever comes first. A minimum of 12 hr of infusion recommended. For patient undergoing CABG surgery, infusion discontinued prior to surgery.

**DOSAGE ADJUSTMENT** For patient with serum creatinine level less than 50 ml/min, initial and subsequent bolus remains

unchanged at 180 mcg/kg but continuous infusion decreased to 1.0 mcg/kg/min.

Route	Onset	Peak	Duration
I.V.	Immediate	In 15 min	4–8 hr

## Mechanism of Action

Reversibly inhibits platelet aggregation by preventing fibrinogen, von Willebrand factor, and other adhesive ligands from binding to glycoprotein IIb/IIIa receptors on activated platelets. As a result, eptifibatide disrupts final cross-linking stage of platelet aggregation—and thrombus formation.

## Incompatibilities

Don't administer eptifibatide through the same I.V. line as furosemide.

## Contraindications

Active bleeding, bleeding diathesis, or stroke during prior 30 days, current or planned administration of another parenteral GP IIb/IIIa inhibitor, dependency on dialysis, history of hemorrhagic stroke, hypersensitivity to eptifibatide or its components, major surgery during previous 6 weeks, severe uncontrolled hypertension (systolic pressure above 200 mm Hg, diastolic pressure above 110 mm Hg)

## Interactions

### DRUGS

*anticoagulants, other antiplatelet agents, other platelet aggregation inhibitors (especially inhibitors of platelet receptor glycoprotein IIb/IIIa, such as abciximab)*  
*thrombolytics*: Increased risk of additive pharmacologic effects, increased risk of bleeding

## **Adverse Reactions**

**CNS:** Intracranial hemorrhage

**CV:** Hypotension

**GI:** GI hemorrhage, hematemesis

**GU:** Hematuria

**HEME:** Bleeding that may be severe, decreased hemoglobin level, immune-mediated thrombocytopenia, thrombocytopenia

**RESP:** Pulmonary hemorrhage

**Other:** Anaphylaxis

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Expect to obtain APTT and PT as a baseline and hematocrit and hemoglobin, platelet count, and serum creatinine during therapy
- Withdraw bolus dose of eptifibatide from a 10-ml (2 mg/ml) vial into a syringe.
- Using vented I.V. infusion set, give continuous infusion directly from the 100-ml (0.75 mg/ml) vial. Be sure to center the spike in the circle on top of vial stopper.
- Expect to keep APTT between 50 and 70 seconds or per facility protocol during therapy unless patient has PTCA.
- Be aware that if patient has PTCA, expect to maintain activated clotting time between 200 and 250 seconds during the procedure.
- Avoid arterial and venous punctures, I.M. injections, urinary catheters, nasotracheal or nasogastric intubation, and use of noncompressible I.V. sites, such as subclavian and jugular veins during therapy.
- Expect to discontinue eptifibatide and heparin and monitor patient closely if platelet count falls below 100,000/mm<sup>3</sup>.
- Plan to stop drug, as prescribed, if patient undergoes coronary artery bypass surgery.

## PATIENT TEACHING

- Instruct patient to immediately report bleeding during eptifibatide therapy.
- Reassure patient that he'll be monitored closely throughout therapy.
- Advise patient to avoid activities that may lead to bruising and bleeding.

**eravacycline**

**Xerava**

# Class and Category

*Pharmacologic class:* Synthetic tetracycline

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat complicated intra-abdominal infections caused by Bacteroides species, Citrobacter freundii, Clostridium perfringens, Enterobacter cloacae, Enterococcus faecalis, E. faecium, Escherichia coli, Klebsiella oxytoca, K. pneumoniae, Parabacteroides distasonis, Staphylococcus aureus, or Streptococcus anginosus group*

### I.V. INFUSION

**Adults.** 1 mg/kg infused over 60 min every 12 hr for 4 to 14 days.

***DOSAGE ADJUSTMENT*** For patient with severe hepatic impairment, 1 mg/kg administered every 12 hr on day 1 followed by 1 mg/kg every 24 hr starting on day 2 for up to 14 days.

## Mechanism of Action

Passes through the bacterial lipid bilayer, where it binds reversibly to 30S ribosomal subunits to block the binding of aminoacyl transfer RNA to messenger RNA. This inhibits bacterial protein synthesis.

## Incompatibilities

Do not infuse with any other drugs or solutions except for 0.9% sodium chloride injection, USP

# Contraindications

Hypersensitivity to eravacycline, tetracycline-class antibacterials, or their components

# Interactions

## DRUGS

*anticoagulants*: Possibly depressed plasma prothrombin activity

*strong CYP3A inducers*: Decreased exposure of eravacycline with possible decreased effectiveness

# Adverse Reactions

**CNS**: Anxiety, depression, dizziness, insomnia

**CV**: Chest pain, **hypotension**, palpitations

**EENT**: Distorted sense of taste, tooth discoloration

**GI**: **Acute pancreatitis, *Clostridium difficile*-associated diarrhea**, elevated liver enzymes, nausea, **pancreatic necrosis**, vomiting

**GU**: Elevated creatinine

**HEME**: **Decreased white blood cell count, neutropenia, prolonged activated partial thromboplastin time**

**MS**: Inhibited bone growth

**RESP**: Dyspnea, pleural effusion

**SKIN**: Excessive sweating, rash

**Other**: **Anaphylaxis, hypocalcemia**, infusion-site reactions

# Childbearing Considerations

## PREGNANCY

- Drug can cause fetal harm such as adverse effects on skeletal and tooth development when given during the second and third trimester of pregnancy.
- The use of drug during last half of pregnancy may cause permanent discoloration of the child's teeth.
- Drug should not be used during pregnancy unless there is no alternative and benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk although other tetracyclines are.
- Breastfeeding is not recommended during drug therapy and for 4 days after last dose.

## REPRODUCTION

- Drug may cause impaired spermiation and sperm maturation resulting in abnormal sperm morphology and poor motility based on animal studies.

# Nursing Considerations

- Be aware that drug may cause permanent tooth discoloration if given during tooth development and therefore should be avoided in pregnant women during the last half of the pregnancy.
- Reconstitute 50-mg vial with 5 ml of 0.9% Sodium Chloride Injection, USP or Sterile Water for Injection, USP. Gently swirl vial until powder is completely dissolved. Do not shake solution, to avoid foaming. Reconstituted solution should appear clear and pale yellow to orange. Stability of the solution after reconstitution in the vial is 1 hour at room temperature. If it is not further diluted as follows within 1 hour, the reconstituted vial must be discarded. Further dilute in an 0.9% sodium chloride infusion bag to a target concentration of 0.3 mg/ml. Do not shake

the diluted bag. Infuse over 60 min. Infuse within 24 hours of preparation if stored at room temperature or within 7 days if refrigerated.

**WARNING** Monitor patient for hypersensitivity reactions, which could become life-threatening. If an allergic reaction occurs, stop eravacycline immediately, notify prescriber, and provide emergency care as prescribed.

- Assess patient for signs of secondary infection, such as profuse, watery diarrhea. If such diarrhea develops, contact prescriber and expect drug to be withheld if pseudomembranous colitis caused by *Clostridium difficile* occurs. Be prepared to treat with electrolyte replacement, fluids, and protein as well as an antibiotic effective against *C. difficile*.

## PATIENT TEACHING

- Instruct patient to immediately report any signs of an allergic reaction.
- Urge patient to notify prescriber if diarrhea develops, even 2 months or more after eravacycline therapy has been discontinued.
- Inform pregnant women to notify prescriber if pregnant, because eravacycline may cause permanent tooth discoloration if given during the second and third trimesters of pregnancy.
- Advise women not to breastfeed during eravacycline therapy and for 4 days after the last dose of eravacycline.

**erenumab-aooe**

**Aimovig**

## Class and Category

*Pharmacologic class:* Human monoclonal antibody

*Therapeutic class:* Antimigraine

# Indications and Dosages

➤ *To prevent migraine headaches*

## SUBCUTANEOUS INJECTION

**Adults.** 70 mg to 140 mg (given as two 70-mg consecutive injections) monthly.

Route	Onset	Peak	Duration
SQ	Unknown	4 to 6 days	Unknown

## Mechanism of Action

Binds to the calcitonin gene-related peptide (CGRP) receptor. The CGRP receptor is thought to be responsible for transmitting signals that can cause incapacitating pain. By binding to the CGRP receptor, the drug antagonizes its function, preventing pain signals from being transmitted.

## Contraindications

Hypersensitivity to erenumab-aooe or its components

## Interactions

### DRUGS

None reported

## Adverse Reactions

**GI:** Constipation (may become severe)

**MS:** Muscle cramps or spasms

**SKIN:** Rash

**Other:** **Anaphylaxis, angioedema**, erenumab-aooe antibody formation, injection-site reactions (erythema, pain, pruritus)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Know that women with migraine may be at increased risk of preeclampsia during pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that the needle shield within the white cap of the prefilled autoinjector and the gray needle cap of the prefilled syringe contain dry natural rubber, a derivative of latex. Handling the caps may cause allergic reactions in individuals sensitive to latex.
- Allow erenumab-aooe to sit at room temperature for at least 30 minutes protected from direct sunlight prior to administration. Drug should not be warmed by using a heat source such as hot water or a microwave. Do not shake the product. Inspect solution for discoloration or particulate matter prior to administration. Do not use if solution is cloudy or discolored or contains flakes or particles.
- Administer in the abdomen, thigh, or upper arm subcutaneously. Do not inject into areas where the skin is bruised, hard, red, or tender.
- Monitor effectiveness of drug to relieve migraine headaches.

**WARNING** Monitor patient for hypersensitivity reactions, which usually are not serious and occurs within hours of administration. However, some have occurred more than one week after administration and some have been serious or severe. Be prepared to initiate appropriate treatment if serious or severe and expect drug to be discontinued.

- Monitor patient for constipation, which could become severe with serious complications requiring hospitalization. Patients who are taking drugs that decrease gastrointestinal motility are at increased risk.

## **PATIENT TEACHING**

- Instruct patient how to prepare and administer erenumab-aooe as a subcutaneous injection using the single-dose prefilled autoinjector or single-dose prefilled syringe.
- Warn patient that the needle shield within the white cap of the prefilled autoinjector and the gray needle cap of the prefilled syringe contain dry natural rubber, a derivative of latex. Handling the caps may cause allergic reactions in individuals sensitive to latex.
- Tell patient to allow drug to sit at room temperature for at least 30 minutes protected from direct sunlight. Caution patient not to warm drug by using a heat source such as hot water or a microwave. Also caution patient not to shake the syringe. Instruct patient to inspect solution for discoloration or particulate matter prior to administration. Tell him not to use solution if it is cloudy or discolored or contains flakes or particles. Remind him that both the prefilled autoinjector and prefilled syringe are single-dose and to deliver the entire contents with each injection.
- Inform patient prescribed the 140-mg dose to administer the drug once a month as two separate but consecutive subcutaneous injections of 70 mg each.
- Instruct patient to administer the injection in the abdomen, thigh, or upper arm subcutaneously. Advise patient not to inject into areas where the skin is bruised, hard, red, or tender.
- Inform patient that drug may cause injection-site reactions such as itching, pain, or redness. Also tell patient that muscle cramps or spasms may occur, as well as constipation.

- Instruct patient that if a dose is missed, he should administer drug as soon as possible. Thereafter, drug can be given monthly from the date of that dose.

**WARNING** Alert patient that hypersensitivity reactions may occur even as late as one week after administration. Although most are not serious, stress importance of seeking immediate medical attention if difficulty breathing or swallowing occurs.

- Inform patient that constipation is one of the most common adverse reactions related to drug use. However, tell patient to report constipation that is prolonged or severe because a bowel obstruction could occur if left untreated.

## ertapenem sodium

**Invanz**

### Class and Category

*Pharmacologic class:* Carbapenem

*Therapeutic class:* Antibiotic

### Indications and Dosages

- *To treat moderate to severe infections, such as acute pelvic infections (including postpartum endomyometritis, postsurgical gynecologic infections, or septic abortion) due to Bacteroides fragilis, Escherichia coli, Peptostreptococcus species, Prevotella bivia, Porphyromonas asaccharolytica, or*

*Streptococcus agalactiae*; community-acquired pneumonia due to *Haemophilus influenzae* (beta-lactamase-negative strains only), *Moraxella catarrhalis*, or *Streptococcus pneumoniae* (penicillin-susceptible strains only, including cases with concurrent bacteremia); complicated intra-abdominal infections due to *B. distasonis*, *B. fragilis*, *B. ovatus*, *B. thetaiotaomicron*, *B. uniformis*, *Clostridium clostridioforme*, *E. coli*, *Eubacterium lentum*, or *Peptostreptococcus* species; complicated skin and skin-structure infections, including diabetic foot infections without osteomyelitis, due to *B. fragilis*, *E. coli*, *Klebsiella pneumoniae*, *Peptostreptococcus* species, *Porphyromonas asaccharolytica*, *P. bivia*, *Proteus mirabilis*, *Staphylococcus aureus*, *S. agalactiae*, or *S. pyogenes*; and complicated UTI (including pyelonephritis) due to *E. coli* (including cases with concurrent bacteremia) or *K. pneumoniae*

## **I.V. INFUSION**

**Adults and adolescents.** 1 g daily, infused over 30 min, 3 to 10 days for acute pelvic infections, 10 to 14 days for community acquired pneumonia, 5 to 14 days for complicated intra-abdominal infections, 7 to 14 days for complicated skin and skin structure infections including diabetic foot infections, and 10 to 14 days for complicated urinary tract infections

**Children ages 3 months to 13 years.** 15 mg/kg twice daily, infused over 30 min, for 3 to 10 days for acute pelvic infections, 10 to 14 days for community acquired pneumonia, 5 to 14 days for complicated intra-abdominal infections, 7 to 14 days for complicated skin and skin structure infections including diabetic foot infections, and

10 to 14 days for complicated urinary tract infections.  
*Maximum:* 1 g daily.

## **I.M. INJECTION**

**Adults and adolescents.** 1 g daily for up to 7 days.

**Children ages 3 months to 13 years.** 15 mg/kg twice daily for up to 7 days. *Maximum:* 1 g daily.

➤ *To provide prophylaxis of surgical site infection following elective colorectal surgery*

## **I.V. INFUSION**

**Adults.** 1 g infused over 30 min, given 1 hr prior to surgical incision.

***DOSAGE ADJUSTMENT*** Dosage decreased to 500 mg daily for patients with advanced renal insufficiency (creatinine clearance less than or equal to 30 ml/min) or end-stage renal insufficiency (creatinine clearance less than or equal to 10 ml/min). For patients on hemodialysis who have received 500 mg of ertapenem within 6 hr of hemodialysis, supplemental dose of 150 mg given after hemodialysis.

## **Mechanism of Action**

Inhibits bacterial cell wall synthesis by binding to specific penicillin-binding proteins inside the cell wall. Penicillin-binding proteins are responsible for various steps in bacterial cell wall synthesis. By binding to these proteins, ertapenem leads to bacterial cell wall lysis.

## **Incompatibilities**

Don't mix ertapenem with other drugs. Don't dilute it with solutions containing dextrose.

# Contraindications

Hypersensitivity to ertapenem, beta-lactams, other drugs in the same class, or their components; hypersensitivity to local anesthetics of the amide type (I.M. injection)

# Interactions

## DRUGS

*probenecid*: Increased ertapenem half-life, increased and prolonged blood ertapenem level

*valproic acid*: Possibly decreased serum valproic acid level and increased risk of breakthrough seizures

# Adverse Reactions

**CNS:** Abnormal coordination, aggression, agitation, anxiety, asthenia, confusion, delirium, depressed level of consciousness, disorientation, dizziness, dyskinesia, fatigue, fever, gait disturbance, hallucinations, headache, hypothermia, insomnia, mental changes, myoclonus, **seizures**, somnolence, stupor, tremor

**CV:** Chest pain, edema, hypertension, **hypotension**, tachycardia, thrombophlebitis

**EENT:** Nasopharyngitis, oral candidiasis, rhinitis, rhinorrhea, teeth staining, viral pharyngitis

**ENDO:** Hyperglycemia

**GI:** Abdominal pain, acid regurgitation, anorexia, **Clostridium difficile-associated diarrhea**, constipation, diarrhea, elevated liver enzymes, indigestion, nausea, **small intestine obstruction**, vomiting

**GU:** Dysuria, elevated serum creatinine level, genital rash, proteinuria, RBCs and WBCs in urine, UTI, vaginitis

**HEME:** Anemia, decreased hematocrit, eosinophilia, leukocytosis, **leukopenia**, **neutropenia**, **prolonged PT**, **thrombocytopenia**, thrombocytosis

**MS:** Arthralgia, leg pain, muscle weakness

**RESP:** **Atelectasis**, cough, crackles, dyspnea, pleural effusion, pneumonia, **respiratory distress**, upper respiratory tract infection, wheezing

**SKIN:** Cellulitis, dermatitis, erythema, extravasation, pruritus, rash

**Other:** **Anaphylaxis**, **death**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, **hyperkalemia**, **hypokalemia**, infusion-site induration, pain, phlebitis, pruritus, redness, swelling, or warmth

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Obtain sputum, urine, or other specimens for culture and sensitivity testing, as ordered, before giving ertapenem. Expect to start therapy before results are available.
- For I.V. use, know that when preparing drug for I.V. use, reconstitute 1 g with 10 ml of sterile water for injection, 0.9% sodium chloride injection, or bacteriostatic water for injection. Don't use solutions that contain dextrose. Shake well to dissolve. Immediately transfer reconstituted drug to 50 ml normal saline solution. Use within 6 hours if stored at room temperature, 24 hours if refrigerated at 5° C (41° F). Don't freeze. Give I.V. infusion over 30 minutes.
- Inspect drug for particles and discoloration after reconstitution.
- For I.M. injection, reconstitute 1 g of drug with 3.2 ml of 1% lidocaine hydrochloride injection (without epinephrine). Shake thoroughly to form solution. Use within 1 hour after preparation. Withdraw contents of vial and inject deep into a large muscle mass such as the gluteal muscle.

**WARNING** Don't give reconstituted I.M. solution by I.V. route because of possible adverse reaction to lidocaine hydrochloride injection used to reconstitute drug.

- Monitor patient closely for a life-threatening anaphylactic reaction. Patients with a history of hypersensitivity to cephalosporins, penicillin, other allergens or other beta-lactams are at increased risk.

**WARNING** Know that if drug triggers an anaphylactic reaction, stop drug, notify prescriber immediately, and provide appropriate therapy. Anaphylaxis requires immediate treatment with epinephrine as well as airway management and administration of I.V. corticosteroids and oxygen, as needed.

- Be aware that patients with a history of seizures, other CNS disorders that predispose them to seizures (such as brain lesions), or compromised renal function may be at increased risk for seizures. Administer anticonvulsant, as ordered.
- Monitor patient for diarrhea during and for at least 2 months after drug therapy; diarrhea may signal pseudomembranous colitis caused by *C. difficile*. If diarrhea occurs, notify prescriber and expect to withhold

ertapenem and treat with an antibiotic effective against *C. difficile*, electrolytes, fluids, and protein.

- Be aware that because ertapenem is excreted in breast milk, its use by nursing mothers should be carefully evaluated.

## PATIENT TEACHING

- Instruct patient receiving ertapenem to immediately report signs of anaphylaxis, such as itching, rash, or shortness of breath; or signs of superinfection, such as severe diarrhea or white patches on tongue or in mouth.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.
- Alert patient taking divalproex or valproic acid for seizure control to notify prescriber of this type of concurrent therapy because ertapenem may interfere with these drugs' effectiveness to control seizures.

# ertugliflozin

## Steglatro

## Class and Category

*Pharmacologic class:* Sodium glucose-dependent cotransporter inhibitor

*Therapeutic class:* Antidiabetic

## Indications and Dosages

- *As adjunct to improve glycemic control in patients with type 2 diabetes mellitus*

## **TABLETS**

**Adults.** *Initial:* 5 mg once daily in morning, increased as needed. *Maximum:* 15 mg once daily.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.	Unknown	1 hr	Unknown

## **Mechanism of Action**

Inhibits sodium glucose link transporter-2 to reduce renal reabsorption of filtered glucose and lower the renal threshold for glucose. These actions increase urinary glucose excretion and lower blood glucose levels.

## **Contraindications**

Dialysis, end-stage renal disease, hypersensitivity to ertugliflozin or its components, severe renal impairment

## **Interactions**

### **DRUGS**

*insulin, insulin secretagogues:* Increased risk of hypoglycemia

## **Adverse Reactions**

**CNS:** Headache, thirst

**CV:** Elevated low-density lipoprotein cholesterol, **hypotension**

**EENT:** Nasopharyngitis

**ENDO:** **Ketoacidosis**

**GU:** Acute kidney injury and impairment, acute prerenal failure, decreased estimated glomerular filtration rate, elevated serum creatinine levels, genital mycotic infections, increased urination, necrotizing fasciitis of the perineum (Fournier's gangrene), pyelonephritis, urosepsis, UTI, vaginal pruritus

**HEME:** Increased hemoglobin level

**MS:** Back pain

**Other:** Dehydration, elevated serum phosphate level, hyperphosphatemia, weight loss

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm, especially on the renal system.
- Drug is not recommended during the second and third trimesters of pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding is not recommended because kidney maturation continues through the first 2 years of life.

## Nursing Considerations

- Know that volume depletion should be corrected before ertugliflozin therapy is begun.
- Assess patient for factors that may predispose patient to acute kidney injury before ertugliflozin therapy is begun. Risk factors may include presence of chronic renal insufficiency, congestive heart failure, and hypovolemia and use of drugs such as ACE inhibitors, ARBs, diuretics, and

NSAIDs. Be aware ertugliflozin should not be initiated in patients who have an estimated glomerular filtration rate (eGFR) between 30 and 60 ml/min nor should it be prescribed for patients with an eGFR below 30 ml/min. If eGFR falls between 30 and 60 ml/min during drug therapy, continued use is not recommended. Assess renal function before ertugliflozin is initiated and periodically throughout drug therapy, as ordered.

- Review patient's history for any risk factors that may predispose patient to need a lower-limb amputation, such as presence of diabetic foot ulcers, neuropathy, peripheral vascular disease, or a prior amputation, before ertugliflozin therapy is begun. This is because an increased risk for lower-limb amputation has been found with another drug in the same class as ertugliflozin.
- Monitor patient's blood pressure closely because ertugliflozin causes intravascular volume contraction. Those at greater risk include the elderly and patients with impaired renal function or low systolic blood pressure or with concomitant use of diuretics.

**WARNING** Monitor patient for signs and symptoms of metabolic acidosis. If present, also assess patient for ketoacidosis. Know that patient may have ketoacidosis even if her blood glucose level is less than 250 mg/dl. If ketoacidosis is suspected, notify prescriber. If confirmed, expect ertugliflozin to be discontinued and treatment with carbohydrate, fluid, and insulin replacement to be given.

- Expect ertugliflozin to be withheld when oral intake is reduced, such as in acute illness or fasting, or when fluid losses occur, such as excessive heat exposure or gastrointestinal illness. This is because dehydration increases risk of kidney impairment that could be quite serious.
- Monitor patient for signs and symptoms of infection, new pain or tenderness, sores, or ulcers involving the lower limbs. If present, notify prescriber and expect drug to be discontinued.
- Monitor patients also receiving insulin or an insulin secretagogue such as a sulfonylurea for hypoglycemia. Dosage of these drugs may have to be reduced to minimize the risk of hypoglycemia.
- Assess both men and women for genital mycotic infections, which may occur with ertugliflozin therapy. Patients at higher risk include those with a history of genital mycotic infections or men who are uncircumcised.

**WARNING** Monitor patient for a rare but serious and life-threatening necrotizing infection of the perineum called Fournier's gangrene. Notify prescriber immediately if patient develops erythema, pain, swelling, or tenderness in the genital or perineal area, along with fever or malaise. Expect treatment with broad-spectrum antibiotics and, if needed, surgical debridement of the area. Know that ertugliflozin will be discontinued if this occurs. Monitor patient's blood glucose levels closely and expect an alternative treatment for glycemic control.

## **PATIENT TEACHING**

- Advise patient to take ertugliflozin exactly as prescribed. Tell her if a dose is missed to take it as soon as it's remembered unless it is close to the next dose. Warn patient never to double the dose.
- Inform patients also prescribed insulin or antidiabetic agents known to cause hypoglycemia to monitor blood glucose level closely, as hypoglycemia may occur. Also review the signs and symptoms of hypoglycemia and how to treat.
- Instruct patient to maintain adequate fluid intake, as dehydration increases the risk of the blood pressure dropping. Advise patient to notify prescriber if he experiences dizziness or light-headedness and weakness.

**WARNING** Teach patient how to check urine for ketones and review signs and symptoms of ketoacidosis with patient. Remind patient that ketoacidosis may occur even when her blood glucose is not elevated. Tell patient to seek immediate medical attention if she experiences abdominal pain, labored breathing, nausea, tiredness, and vomiting and ketones are present in urine.

- Instruct patient to report any persistent, severe, or unusual signs and symptoms to prescriber, especially if changes in kidney function occur.

- Inform patient of the potential for an increased risk of amputations. Review preventative foot care with patient. Tell patient to report any infection, new pain or tenderness, sore, or ulcer involving the foot or leg to prescriber and seek immediate medical attention.
- Tell patient to seek medical care if a urinary tract infection occurs, because it can become serious if left untreated.
- Review signs and symptoms of genital mycotic infection such as itching, rash, or redness in the area. Tell patient to notify prescriber if present.

**WARNING** Warn patient to stop ertugliflozin and seek immediate medical attention if pain, redness, swelling, or tenderness occurs in the genital or perineal area along with fever or malaise because, although rare, this cluster of symptoms may become life-threatening.

- Remind patient to monitor her diabetes by testing blood glucose, as she will test positive for glucose in the urine while taking ertugliflozin.
- Advise women of childbearing age to notify prescriber if pregnancy occurs, because ertugliflozin therapy is not recommended during the second and third trimesters of pregnancy.
- Tell women considering breastfeeding that it is not recommended during ertugliflozin therapy because of the potential to cause harm to fetus or neonate's developing kidneys.

## erythromycin

***(contains 250, 333, or 500 mg of base per delayed-release capsule, delayed-release tablet, or tablet)***

**Apo-Erythro (CAN), E-Mycin, Erybid (CAN), ERYC, Ery-Tab, Ilotycin, Novo-Rythro Encap (CAN), PCE**

## **erythromycin ethylsuccinate**

***(contains 1 g of base per 1.6 g of oral suspension or tablet)***

**Apo-Erythro-ES (CAN), E.E.S.,  
EryPed**

## **erythromycin lactobionate**

***(contains 500 or 1,000 mg of base per vial)***

**Erythrocin**

## **erythromycin stearate**

***(contains 125 or 250 mg of base per 5 ml of oral suspension, or 250 or 500 mg of base per tablet)***

**Erythro-S (CAN), Erythrocin  
Stearate**

## **Class and Category**

*Pharmacologic class:* Macrolide

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat mild to moderate respiratory tract infections caused by Haemophilus influenzae, Streptococcus pneumoniae, or Streptococcus pyogenes (group A beta-hemolytic streptococcus)*

### **CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults.** 250 (base) or 400 mg to 800 mg (ethylsuccinate) every 6 hr for 10 days. Alternatively, 500 mg (base) every 12 hr or one half of total daily dose (ethylsuccinate) every 12 hr or one third total daily dose (ethylsuccinate) every 8 hr.

**Children.** 30 to 50 mg (base)/kg daily in divided doses every 6 hr for 10 days. For more severe infection, dosage may be doubled. For *H. influenzae* infections, erythromycin ethylsuccinate is administered with 150 mg/kg daily of sulfisoxazole.

- *To treat severe respiratory tract infections caused by H. influenzae, S. pneumoniae, or S. pyogenes (group A beta-hemolytic streptococcus)*

### **I.V. INFUSION**

**Adults.** 1 to 4 g (lactobionate) daily continuously or in divided doses infused over 20 to 60 min every 6 hr for 10 days.

**Children.** 15 to 20 mg/kg (lactobionate) daily in divided doses infused over 20 to 60 min every 4 to 6 hr for 10 days.

- *To treat respiratory tract infections caused by Mycoplasma pneumoniae*

## **CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults with mild to moderate infection.** 250 to 500 mg (base) or 400 to 800 mg (ethylsuccinate) every 6 hr for up to 3 wk.

### **I.V. INFUSION**

**Adults with severe infection.** 1 to 4 g daily continuously or in divided doses infused over 20 to 60 min every 6 hours.

- *To treat skin and soft-tissue infections caused by S. pyogenes or Staphylococcus aureus*

## **CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults with mild to moderate infection.** 250 mg to 500 mg or 400 mg to 800 mg (ethylsuccinate) every 6 hr.

### **I.V. INFUSION**

**Adults with severe infection.** 1 to 4 g (lactobionate) daily continuously or in divided doses infused over 20 to 60 min every 6 hr for up to 3 wk.

- *To treat pertussis (whooping cough) caused by Bordetella pertussis*

## **CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS**

**Children.** 40 to 50 mg (base)/kg daily in divided doses every 6 hr for 14 days. *Maximum for children 1 month and*

older: 2 g/day.

- *To treat intestinal amebiasis caused by Entamoeba histolytica*

## **CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults.** 250 mg (base or stearate) or 400 mg (ethylsuccinate) every 6 hr or 500 mg (base, stearate) every 12 hr for 10 to 14 days.

**Children.** 30 to 50 mg (base or ethylsuccinate)/kg daily in divided doses for 10 to 14 days.

- *To treat pelvic inflammatory disease caused by Neisseria gonorrhoeae*

## **CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION**

**Adults.** 500 mg (base) I.V. infused over 20 to 60 min every 6 hr for 3 days and then 250 mg to 500 mg (base) P.O. every 6 hr for 7 days.

- *To treat conjunctivitis in newborns*

## **ORAL SUSPENSION**

**Neonates.** 50 mg (base)/kg daily in 4 divided doses for 14 days.

- *To treat pneumonia in neonates caused by Chlamydia trachomatis*

## **I.V. INFUSION**

**Neonates.** 15 to 20 mg/kg (lactobionate) daily continuously or in divided doses infused over 20 to 60 min every 6 hr.

## **ORAL SUSPENSION**

**Neonates.** 50 mg/kg (base, stearate) daily in 4 divided doses for at least 3 wk.

- *To treat urogenital infections caused by C. trachomatis during pregnancy*

## **CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults.** 500 mg (base, stearate) on an empty stomach every 6 hr for 7 days; or 250 mg (base, stearate) on an empty stomach every 6 hr for at least 14 days.

- *To treat nongonococcal urethritis or uncomplicated urethral, endocervical, or rectal infections caused by C. trachomatis*

## **CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults.** 500 mg (base, stearate) every 6 hr for 7 days. If patient can't tolerate high doses, 250 mg (base stearate) every 6 hr for 14 days. Alternatively, 400 to 800 mg (ethylsuccinate) every 6 hr for 7 to 14 days.

- *To treat Legionnaire's disease*

## **CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE**

## **TABLETS, ORAL SUSPENSION, TABLETS, I.V. INFUSION**

**Adults.** 1 to 4 g (base, stearate) daily in divided doses every 6 hr for 10 to 14 days. I.V. dosage infused continuously or, if dosage is divided and given every 6 hr, infused over 20 to 60 min for each dose.

➤ *To prevent rheumatic fever*

## **CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults.** 250 mg (base, stearate) or 400 mg (ethylsuccinate) every 12 hr.

**Children.** 250 mg (base, stearate) twice daily.

➤ *To prevent bacterial endocarditis in patients with penicillin allergy who plan dental or upper respiratory tract surgery*

## **CAPSULES, CHEWABLE TABLETS, DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults.** 1 g (base) or 800 mg (ethylsuccinate) given 2 hr before procedure and then one half of initial dose 6 hr after initial dose.

**Children.** 20 mg (base, stearate)/kg given 2 hr before procedure and then half of initial 6 hr after initial dose.

## **Mechanism of Action**

Binds with the 50S ribosomal subunit of the 70S ribosome in many types of aerobic, anaerobic, gram-negative, and

gram-positive. This action inhibits RNA-dependent protein synthesis in bacterial cells, causing them to die.

## Contraindications

Astemizole, cisapride, dihydroergotamine, ergotamine, lovastatin, pimozone, simvastatin, or terfenadine therapy; hypersensitivity to erythromycin, other macrolide antibiotics, or their components

## Interactions

### DRUGS

*alfentanil*: Decreased alfentanil clearance, prolonged alfentanil action

*aminodarone, dofetilide, procainamide, quinidine, sotalol*: Increased risk of prolonged QT interval

*astemizole, cisapride, pimozone, terfenadine*: Increased risk of cardiotoxicity, prolonged QT interval, torsades de pointes, ventricular tachycardia, and death

*calcium channel blockers such as amlodopine, diltiazem, verapamil*: Increased risk of hypotension

*carbamazepine, valproic acid*: Possibly inhibited metabolism of these drugs, increasing their blood levels and risk of toxicity

*clindamycin*: Antagonized effects of these drugs

*colchicine*: Possible life-threatening colchicine toxicity

*cyclosporine*: Increased risk of nephrotoxicity

*digoxin*: Increased serum digoxin level and risk of digitalis toxicity

*dihydroergotamine, ergotamine*: Decreased ergotamine metabolism, increased risk of ergot toxicity with ischemia and vasospasm

*HMG-CoA reductase inhibitors such as atorvastatin, lovastatin, simvastatin:* Possibly increased risk of rhabdomyolysis  
*midazolam, triazolam, and other related benzodiazepines:* Increased pharmacologic effects of these drugs  
*oral anticoagulants:* Increased anticoagulant effects, especially in the elderly  
*oral contraceptives:* Decrease or loss of effectiveness of oral contraceptive  
*sildenafil:* Increased effects of sildenafil  
*verapamil:* Increased risk of bradyarrhythmias, hypotension, and lactic acidosis  
*xanthines (except dyphylline):* Increased serum theophylline level with high doses and risk of theophylline toxicity

## **ACTIVITIES**

*alcohol use:* Increased alcohol level (by 40%) with I.V. erythromycin

## **Adverse Reactions**

**CNS:** Fatigue, fever, malaise, weakness

**CV:** **Prolonged QT interval, torsades de pointes, ventricular arrhythmias**

**EENT:** Hearing loss, oral candidiasis

**GI:** Abdominal cramps and pain, **Clostridium difficile-associated diarrhea**, diarrhea, **hepatotoxicity**, infantile hypertrophic pyloric stenosis, nausea, vomiting

**GU:** Interstitial nephritis, jaundice, vaginal candidiasis

**MS:** New or aggravated myasthenia gravis syndrome

**SKIN:** Erythema, pruritus, rash

**Other:** Fluid overload (from I.V. infusion), injection-site inflammation and phlebitis

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Be aware that erythromycin should not be used in patients with history of QT-interval prolongation or in patients with ongoing proarrhythmic conditions such as uncorrected hypokalemia or hypomagnesemia, serious bradycardia, and in patients receiving Class IA or Class III antiarrhythmic agents. Monitor the elderly closely as well because they are more susceptible to drug effects on the QT interval.
- Use erythromycin cautiously in patients with impaired hepatic function because drug is metabolized by the liver.
- Use erythromycin cautiously in elderly patients, especially those with renal or hepatic dysfunction, because these patients are at increased risk of hearing loss and torsades de pointes. They're also at increased risk of bleeding if taking an oral anticoagulant.
- Expect to obtain body fluid or tissue sample for culture and sensitivity testing before giving first erythromycin dose.
- Reconstitute parenteral form before administration. Add at least 10 ml of preservative-free sterile water for injection to each 500-mg vial or at least 20 ml of diluent to each 1-g vial.

- For prolonged infusion, expect to infuse a buffered solution up to 24 hours after dilution.
- For intermittent infusion, dilute dose in 100 to 250 ml normal saline solution or D<sub>5</sub>W if needed; give slowly over 20 to 60 minutes.
- When giving I.V. erythromycin lactobionate, dilute the solution, if needed, to 1 to 5 mg/ml in normal saline solution, lactated Ringer's solution, or other electrolyte solution for slow, continuous infusion. Diluted solution remains potent for 14 days if refrigerated and for 24 hours at room temperature.
- Be aware that infusions prepared in piggyback infusion bottles stay potent for 30 days if frozen, 24 hours if refrigerated, or 8 hours at room temperature. Don't store infusions prepared in the ADD-Vantage system.
- Don't use diluent with benzyl alcohol if parenteral erythromycin is for a neonate. It may cause a fatal toxic syndrome of CNS depression, hypotension, metabolic acidosis, renal failure, respiratory problems, and, possibly, intracranial hemorrhage and seizures.
- Monitor liver enzymes periodically to detect hepatotoxicity, which is most common with erythromycin estolate. Signs typically appear within 2 weeks after continuous therapy starts and resolve when it stops.
- Assess hearing regularly, especially in elderly patients and those who receive 4 g or more daily or have hepatic or renal disease. Hearing impairment begins 36 hours to 8 days after treatment starts and usually begins to improve 1 to 14 days after it stops.
- Watch for evidence of fluid overload, such as acute dyspnea and crackles, during I.V. therapy.
- Monitor infants for vomiting or irritability with feeding because infantile hypertrophic pyloric stenosis has been reported.
- Assess myasthenia gravis patients for weakness because drug may aggravate it. Keep in mind that myasthenic syndrome may arise in patients previously undiagnosed with myasthenia gravis.
- Watch closely for signs and symptoms of superinfection. If they occur, notify prescriber and expect to stop drug and provide appropriate therapy.
- Monitor patient for diarrhea during and for at least 2 months after erythromycin therapy; diarrhea may signal pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold drug and treat with fluids, electrolytes, protein, and an antibiotic effective against *C. difficile*.

- Know that if patient receives an order for urine catecholamine analysis, notify prescriber because erythromycin interferes with fluorometric measurement of urine catecholamines.

## PATIENT TEACHING

- Urge patient to complete prescribed therapy, even if he feels better before it's finished.
- Tell patient to notify prescriber if symptoms worsen or don't improve after a few days.
- Teach patient how to administer prescribed form of erythromycin. Instruct him to swallow capsules or tablets whole. For an oral suspension, teach him to use the calibrated measuring device provided to ensure accurate doses. Remind him to shake the suspension before measuring a dose.
- Advise patient to take oral form of erythromycin with a full glass of water on an empty stomach (except erythromycin ethylsuccinate, which is better absorbed with food).
- Instruct patient to take oral form with food if GI distress occurs.
- Instruct patient to promptly notify prescriber if he develops allergic reactions, hearing changes, or signs of hepatic dysfunction.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that watery or bloody stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.

**escitalopram oxalate**

**Lexapro**

## Class and Category

*Pharmacologic class:* Selective serotonin reuptake inhibitor (SSRI)

*Therapeutic class:* Antidepressant

## Indications and Dosages

➤ *To treat generalized anxiety disorder*

### ORAL SOLUTION, TABLETS

**Adults.** *Initial:* 10 mg daily in morning or evening, increased to 20 mg daily after 1 or more wk, as needed.

➤ *To treat major depression*

### ORAL SOLUTION, TABLETS

**Adults.** *Initial:* 10 mg daily, morning or evening, increased to 20 mg daily after 1 wk, as needed.

**Adolescents ages 12 to 17.** *Initial:* 10 mg daily, morning or evening, increased to 20 mg daily after 3 wk, as needed.

***DOSAGE ADJUSTMENT*** Dosage shouldn't exceed 10 mg daily for elderly patients and those with hepatic impairment.

## Mechanism of Action

Inhibits reuptake of the neurotransmitter serotonin by CNS neurons, thereby increasing the amount of serotonin available in nerve synapses. An elevated serotonin level may result in elevated mood and reduced anxiety or depression.

## Contraindications

Concomitant therapy with pimozide; hypersensitivity to escitalopram, citalopram or its components; use within 14 days of MAO inhibitor therapy including intravenous methylene blue or linezolid

# Interactions

## DRUGS

*amphetamines, buspirone, fentanyl, lithium, St. John's wort, tramadol, tricyclic antidepressants, triptans.*

*tryptophan:* increased risk of serotonin syndrome

*aspirin, NSAIDs, warfarin:* Possibly increased risk of bleeding

*carbamazepine:* Possibly increased clearance of escitalopram

*cimetidine:* Possibly increased plasma escitalopram level

*CNS drugs:* Additive CNS effects

*lithium:* Possible enhancement of the serotonergic effects of escitalopram

*MAO inhibitors:* Possibly hyperpyretic episodes, hypertensive crisis, serotonin syndrome, and severe seizures

*metoprolol:* Increased plasma metoprolol levels with decreased cardioselectivity of metoprolol

*pimozide:* Increased risk of QT prolongation

*sumatriptan:* Increased risk of hyperreflexia, incoordination, and weakness

*triptans:* Increased risk of serotonin syndrome

## ACTIVITIES

*alcohol use:* Possibly increased cognitive and motor effects of alcohol

## Adverse Reactions

**CNS:** Abnormal gait, acute psychosis, aggression, akathisia, delirium, dizziness, dyskinesia, dystonia, extrapyramidal effects, fatigue, headache, hypomania, insomnia, lethargy, mania, myoclonus, **neuroleptic**

**malignant syndrome**, paresthesia, **seizures**, **serotonin syndrome**, somnolence, **suicidal ideation**

**CV:** **Atrial fibrillation**, **cardiac failure**, **deep vein thrombosis**, **hypotension**, **MI**, **prolonged QT interval**, **torsades de pointes**, **ventricular arrhythmias**

**EENT:** Acute-angle glaucoma, diplopia, dry mouth, nystagmus, rhinitis, sinusitis, toothache, visual hallucinations

**ENDO:** Diabetes mellitus, hyperprolactinemia, syndrome of inappropriate ADH secretion

**GI:** Abdominal pain, constipation, decreased appetite, diarrhea, flatulence, **GI bleeding or hemorrhage**, **hepatic necrosis**, **hepatitis**, indigestion, nausea, **pancreatitis**, **rectal hemorrhage**, vomiting

**GU:** **Acute renal failure**, anorgasmia, decreased libido, ejaculation disorders, impotence, priapism

**HEME:** **Bleeding**, **decreased prothrombin time**, **hemolytic anemia**, **leukopenia**, **thrombocytopenia**

**MS:** Neck or shoulder pain, **rhabdomyolysis**

**RESP:** **Pulmonary embolism**

**SKIN:** Ecchymosis, **erythema multiforme**, increased sweating, photosensitivity, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, flu-like symptoms, **hyponatremia**

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm. However, be aware that neonates exposed to the drug late in the third trimester of pregnancy may develop serious and life-threatening adverse reactions, which can arise immediately following birth. These adverse reactions may require prolonged hospitalization, respiratory support, and tube feeding.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, infant should be monitored for decreased feeding, excessive drowsiness, and weight loss.

## Nursing Considerations

- Use escitalopram cautiously in patients with history of mania or seizures, patients with severe renal impairment, and those with diseases or conditions that produce altered metabolism or hemodynamic responses.

**WARNING** Know that when escitalopram dosage increases, monitor patient for possible serotonin syndrome, which may include agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. In its most severe form, serotonin syndrome can resemble neuroleptic malignant syndrome, which includes autonomic instability with possible changes in vital signs, a high fever, muscle rigidity, and mental status changes.

- Be aware that escitalopram should not be given to patients with bradycardia, congenital long QT syndrome, hypokalemia or hypomagnesemia, recent acute myocardial infarction, or uncompensated

heart failure because of increased risk of prolonged QT interval and torsades de pointes. It should also not be given to patients who are taking other drugs that prolong the QT interval. Expect hypokalemia and hypomagnesemia to be corrected before escitalopram therapy is begun.

- Monitor patient—especially elderly patient—for hypo-osmolality of serum and urine and for hyponatremia (headache, impaired memory, trouble concentrating, unsteadiness, weakness) because they may indicate escitalopram-induced syndrome of inappropriate ADH secretion.
- Watch for signs of abuse or misuse; drug's potential for physical and psychological dependence is unknown.
- Monitor patient for bleeding, especially if patient is also taking an anticoagulant, aspirin, or an NSAID. Bleeding can range from ecchymoses, epistaxis, hematomas, and petechiae to life-threatening hemorrhages.
- Expect prescriber to reassess patient periodically to determine the continued need for therapy and evaluate dosage.
- Know that if patient (particularly an adolescent) takes escitalopram for depression, she must be watched closely for suicidal tendencies, especially when therapy starts or dosage changes, because depression may worsen temporarily.
- Expect to taper dosage to avoid serious adverse reactions when therapy is no longer needed.

## **PATIENT TEACHING**

- Inform patient that alcohol use isn't recommended during escitalopram therapy because it may decrease his ability to think clearly and perform motor skills.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient that drug shouldn't be taken with citalopram hydrobromide because of potentially additive effects.
- Tell patient that improvement may not be noticed for 1 to 4 weeks after therapy begins. Emphasize the importance of continuing therapy as prescribed.
- Urge caregivers to watch closely for suicidal tendencies, especially when therapy starts or dosage changes.

- Warn patient not to stop taking drug abruptly. Explain that gradual tapering helps to avoid withdrawal symptoms.
- Urge patient to inform prescriber of any OTC drugs he takes because of potential for interactions.
- Review signs and symptoms of hyponatremia, and instruct patient to report them to prescriber.
- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute-angle glaucoma. Encourage patient to have an eye exam before starting therapy to see if he is at risk.
- Warn patient that escitalopram increases bleeding risk if taken with an anticoagulant, aspirin, or an NSAID and that bleeding events could range from mild to severe. Tell patient to seek emergency care for serious or prolonged bleeding.
- Instruct patient to notify prescriber promptly of any persistent, severe, or unusual signs and symptoms.

## esketamine

### Spravato

## Class and Category

*Pharmacologic class: Ionotropic glutamate receptor*

*Therapeutic class: Antidepressant*

*Controlled substance schedule: III*

## Indications and Dosages

- *As adjunct with an oral antidepressive for treatment-resistant depression*

### NASAL SPRAY

**Adults.** *Induction phase (wks 1-4):* 56 mg on day 1; 56 or 84 mg twice a wk through wk 4. *Maintenance phase (wks 5-8):* 56 mg or 84 mg once a wk. *Maintenance phase (wk 9 and thereafter):* 56 mg or 84 mg every 2 wk unless weekly dosing is needed.

## **Mechanism of Action**

The mechanism by which esketamine exerts its antidepressant effect is unknown.

## **Contraindications**

Aneurysmal vascular disease (including abdominal and thoracic aorta, intracranial, and peripheral arterial vessels) or arteriovenous malformation; history of intracerebral hemorrhage; hypersensitivity to esketamine, ketamine, or any of their components

## **Interactions**

### **DRUGS**

*CNS depressants (benzodiazepines, opioids):* Increased sedation

*MAOIs, psychostimulants (amphetamines, armodafinil, methylphenidate, modafinil):* Possibly increased blood pressure

### **ACTIVITIES**

*alcohol use:* Increased sedation

## **Adverse Reactions**

**CNS:** Anxiety, cognitive impairment, depression, dissociation, dizziness, euphoria, feeling intoxicated headache, hypoesthesia, insomnia, lethargy, mental impairment, panic attacks, sedation, **suicidal ideation**, tremor, vertigo

**CV:** Hypertension, tachycardia

**EENT:** Dry mouth, nasal discomfort, oropharyngeal pain, taste alteration, throat irritation

**GI:** Constipation, diarrhea, nausea, vomiting

**GU:** Interstitial or ulcerative cystitis, pollakiuria

**MS:** Dysarthria, muscular weakness

**SKIN:** Diaphoresis

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-844-405-6185 or <https://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/antidepressants>.
- Drug may cause fetal harm, based on animal studies.
- Drug therapy is not recommended during pregnancy.

### LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy because of the potential for neurotoxicity in infant.

### REPRODUCTION

- Women of childbearing age should use effective contraception throughout drug therapy.

# Nursing Considerations

- Know that esketamine is available only through a restricted program called the Spravato REMS. To receive drug, patient must be enrolled in the Spravato REMS program prior to administration; understand that drug must be administered under the direct observation of a healthcare provider; and agree to be monitored for at least 2 hours after administration of each treatment session.
- Be aware that esketamine must be administered with an oral antidepressant.
- Administration of esketamine should be given at least 2 hours after patient ate and at least 30 minutes after patient had something to drink, because drug may cause nausea and vomiting after administration.
- Assess patient for psychosis before drug administration because of the potential for dissociation to occur after administration. Also, assess patient for a history of drug abuse or dependency, because drug is a schedule III controlled substance. Monitor patient for signs of abuse or dependence after esketamine therapy is started.

**WARNING** Determine patient's blood pressure before administering drug. Expect a delay in drug administration if blood pressure is greater than 140/90 mmHg. Continue to monitor patient's blood pressure closely after drug therapy for at least 2 hours, as significant increases can occur, especially in the first 1.5 hours after administration. Know that concomitant use with psychostimulants or MAOIs increases risk of blood pressure elevation. Promptly seek emergency assistance if patient displays symptoms of a hypertensive crisis or hypertensive encephalopathy.

- Know that a monitoring period of at least 2 hours is required at each treatment session. Assess patient's blood pressure prior to administration. If baseline blood pressure is elevated (greater than 140 mmHg systolic, greater than 90 mmHg diastolic), drug should not be administered if the increase in blood pressure or intracranial pressure poses a serious risk. Reassess blood pressure about 40 minutes after administration and subsequently as clinically warranted. If blood pressure is decreasing and

patient appears stable for at least 2 hours, patient may be discharged at the end of the post-dose monitoring period; if not, continue to monitor.

- Do not prime nasal spray before use. Expect to use 2 devices for a 56-mg dose or 3 devices for an 84-mg dose, with a 5-minute rest period between use of each device. (Each device delivers two sprays containing a total of 28 mg of esketamine.)
- Administer drug by first having patient blow his or her nose. Check expiration date on package. Peel blister and remove device. Check that indicator shows 2 green dots. If not, dispose of device and get a new one. Hand device to patient. Instruct patient to hold device with thumb gently supporting the plunger. Patient should not press the plunger yet. Instruct patient to recline head at about 45 degrees during administration to keep drug inside her nose. Then have patient insert the device tip straight into the first nostril. The device nose rest should touch the skin between the nostrils. Instruct patient to close opposite nostril and breathe through nose while pushing plunger all the way up until it stops. Encourage patient to sniff gently after spraying to keep drug inside nose. Then instruct patient to switch hands to insert tip into the second nostril and repeat the same procedure. After administration, take device from patient and check that indicator shows no green dots. If a green dot is visible, have patient spray again into the second nostril. Check again to confirm that device is empty. Have patient rest in a comfortable position (preferably semi-reclined) for 5 minutes before using next device. If liquid drips out, have patient dab nose with a tissue. Warn patient not to blow nose. Discard used devices per facility procedure for a schedule III drug.
- Be aware that if patient misses treatment sessions and there is worsening of depression, prescriber may consider returning to patient's previous dosing schedule, such as from every 2 weeks to weekly or weekly to twice weekly.
- Administer a prescribed nasal corticosteroid or nasal decongestant to treat other conditions on an esketamine dosing day at least 1 hour before administering esketamine.
- Monitor patient for suicidal tendencies, particularly when therapy starts and when dosage changes are made.
- Monitor patient for signs and symptoms of cystitis, because esketamine use may increase risk of lower urinary tract symptoms.

## **PATIENT TEACHING**

- Inform patient that esketamine is available only through a restricted program called the Spravato REMS. Review the program requirements with patient.

- Tell patient that drug will be prepared for administration by a healthcare professional. Drug cannot be self-administered at home.
- Caution patient to avoid performing activities that are considered hazardous (such as driving or operating machinery) until effects of sedation are known, as more than half of all patients experience sedation following administration of esketamine.
- Instruct patient that dissociation or perceptual changes (including illusions or distortion of time or space) are the most common psychological effects, which is why patient must be monitored for 2 hours after drug administration.
- Inform patient that drug use may increase risk of physical or psychological dependency. Instruct patient to discuss concerns with prescriber.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Alert women of childbearing age to use effective contraception during drug therapy, as esketamine may cause fetal harm.
- Inform women that breastfeeding is not recommended during drug therapy because of potential adverse neurological effects on infant's nervous system.

## eslicarbazepine acetate

### Aptiom

## Class and Category

*Pharmacologic class:* Carboxamide derivative

*Therapeutic class:* Anticonvulsant

## Indications and Dosages

- *Adjunct or monotherapy to treat partial-onset seizures*

## **TABLETS**

**Adults.** *Initial:* 400 or 800 mg once daily, increased weekly in increments of 400 to 600 mg, as needed. *Maintenance:* 800 mg once daily when used as monotherapy and patient unable to tolerate a 1,200 mg daily dose; 1,600 mg once daily when used as adjunctive therapy and patient did not achieve a satisfactory response with a 1,200 mg daily dose. *Maximum:* 1,600 mg once daily.

**Children age 4 to 17 weighing more than 38 kg (83.6 lb).** *Initial:* 400 mg once daily, increased as needed by no more than 400 mg weekly. *Maintenance:* 800 to 1,200 mg daily. *Maximum:* 1,200 mg daily.

**Children age 4 to 17 weighing 32 kg (70.4 lb) to 38 kg (83.6 lb).** *Initial:* 300 mg once daily, increased as needed by no more than 300 mg weekly. *Maintenance:* 600 to 900 mg daily. *Maximum:* 900 mg daily.

**Children age 4 to 17 weighing 22 kg (48.4 lb) to 31 kg (68.2 lb).** *Initial:* 300 mg once daily, increased as needed by no more than 300 mg weekly. *Maintenance:* 500 to 800 mg daily. *Maximum:* 800 mg daily.

**Children age 4 to 17 weighing 11 kg (24.2 lb) to 21 kg (46.2 lb).** *Initial:* 200 mg once daily, increased as needed by no more than 200 mg weekly. *Maintenance:* 400 to 600 mg daily. *Maximum:* 600 mg daily.

***DOSAGE ADJUSTMENT*** For patients with moderate and severe renal impairment (creatinine clearance less than 50 ml/min), dosage decreased by half beginning with initial dosage. For patients receiving carbamazepine, phenobarbital, phenytoin, or primidone concomitantly, dosage may have to be increased.

## **Mechanism of Action**

Possibly inhibits voltage-gated sodium channels to exert anticonvulsant effect.

## Contraindications

Hypersensitivity to eslicarbazepine acetate or oxcarbazepine and their components

## Interactions

### DRUGS

*carbamazepine, phenobarbital, phenytoin, primidone:*

Decreased plasma concentration of eslicarbazepine

*clobazam, omeprazole, phenytoin:* Increased plasma levels of these drugs

*lovastatin, simvastatin:* Decreased plasma concentration of these drugs

*oral contraceptives:* Decreased effectiveness of oral contraceptives

## Adverse Reactions

**CNS:** Amnesia, aphasia, asthenia, ataxia, attention deficits, confusion, coordination abnormality, depression, disorientation, dizziness, fatigue, gait disturbance, headache, insomnia, lethargy, malaise, memory impairment, psychomotor disturbances, somnolence, **suicidal ideation**, tremor, vertigo

**CV:** Hypertension, peripheral edema

**EENT:** Blurred vision, diplopia, impaired vision, nystagmus

**ENDO:** Decreased serum T3 and T4 levels, syndrome of inappropriate antidiuretic hormone secretion

**GI:** Abdominal pain, constipation, diarrhea, elevated liver enzymes, gastritis, **liver dysfunction**, nausea, vomiting

**GU:** UTI

**HEME:** Agranulocytosis, leukopenia, megaloblastic anemia, pancytopenia, thrombocytopenia

**MS:** Dysarthria

**RESP:** Cough

**SKIN:** Rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

**Other:** Anaphylaxis, angioedema, drug reaction with eosinophilia and systemic symptoms (DRESS), hypochloremia, hyponatremia

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org>.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that eslicarbazepine should not be given as adjunctive therapy with oxcarbazepine.

**WARNING** Monitor patient closely for adverse reactions because many of them are serious and some can become life threatening, such as DRESS multi-organ

hypersensitivity. Notify prescriber immediately, expect drug to be discontinued, and provide emergency supportive care, as ordered.

- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.
- Monitor patient's electrolytes, especially sodium level, as ordered. Hyponatremia may occur as an adverse reaction to eslicarbazepine therapy, especially in the elderly and patients treated with diuretics. Assess patient regularly for signs and symptoms of hyponatremia such as confusion, difficulty concentrating, headache, memory impairment, unsteadiness, and weakness. If present, notify prescriber and expect drug to be discontinued.
- Withdraw eslicarbazepine slowly when discontinued and as ordered to minimize risk of seizures and status epilepticus.

## PATIENT TEACHING

- Instruct patient to take eslicarbazepine exactly as prescribed and not to abruptly stop taking drug without consulting prescriber.
- Warn patient about possible dizziness and unsteadiness that may develop while taking eslicarbazepine. Discourage performing hazardous activities such as driving until the neurologic effects of the drug are known.

**WARNING** Tell patient to discontinue drug immediately and seek emergency medical care if patient develops difficulty breathing, fever, or a rash or experiences facial or throat swelling. Also instruct patient to promptly report other skin reactions such as blistering or exfoliation or other persistent, severe, or unusual signs and symptoms.

- Instruct caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report such tendencies to prescriber immediately.
- Tell female patients taking oral contraceptives to use additional or alternative nonhormonal birth control. Encourage patient to enroll in the

North American Antiepileptic Drug Pregnancy Registry if pregnancy occurs, by calling 1-888-233-2334.

- Advise patient to report symptoms of low sodium such as confusion, irritability, muscle weakness or spasms, tiredness, or more frequent or severe seizure activity.

# esmolol hydrochloride

## Brevibloc

### Class and Category

*Pharmacologic class:* Beta blocker

*Therapeutic class:* Antiarrhythmic, antihypertensive

### Indications and Dosages

- *To treat supraventricular tachycardia including atrial fibrillation and atrial flutter; to control heart rate in noncompensatory sinus tachycardia*

### I.V. INFUSION

**Adults.** Infused continuously with or without a loading dose (loading dose: 500 mcg/kg over 1 min) beginning at 50 mcg/kg/min and titrated up or down as indicated by ventricular response to a dosage range of 25 to 200 mcg/kg/min. Alternatively, the dosage may be titrated in a step-wise fashion as follows: *Step 1:* Optional loading dose of 500 mcg/kg over 1 min, followed by a maintenance infusion of 50 mcg/kg/min for 4 min. *Step 2:* Optional loading dose of 500 mcg/kg over 1 min, if necessary,

followed by a maintenance infusion of 100 mcg/kg/min for 4 min. *Step 3:* Optional loading dose of 500 mcg/kg over 1 min, if necessary, followed by a maintenance dose of 150 mcg/kg/min for 4 min. *Step 4:* If necessary, increase maintenance dose to 200 mcg/kg/min. Continuous or step-wise infusions may be continued for up to 48 hr.

➤ *To treat intraoperative and postoperative hypertension and tachycardia*

## **I.V. INFUSION**

**Adults.** *For immediate control:* 1 mg/kg over 30 sec, followed by an infusion of 150 mcg/kg/min, if needed and adjusted to maintain desired blood pressure and heart rate. *For gradual control:* 500 mcg/kg over 1 min, then a maintenance infusion of 50 mcg/kg/min infused over 4 min. If response is inadequate another 500 mcg/kg may be given over 1 min followed by a maintenance infusion of 100 mcg/kg/min for 4 min. Sequence repeated a third time with 500 mcg/kg that may be given over 1 min followed by a maintenance infusion of 150 mcg/kg/min. Further increases in the maintenance infusion (but with no additional bolus dose) may be given in increments of 50 mcg/kg/min, as needed, over 4 min with each increase until maximum dosage is reached, as needed. *Maximum:* 200 mcg/kg/min for tachycardia; 300 mcg/kg/min for hypertension.

***DOSAGE ADJUSTMENT*** When transitioning from esmolol infusion to alternative drugs, esmolol infusion rate reduced by 50% 30 minutes following the first dose of the alternative drug. After administration of the second dose of the alternative drug, if patient's response is satisfactory and maintained for the first hour, esmolol infusion discontinued.

Route	Onset	Peak	Duration
I.V.	Immediate	Unknown	10-20 min

## Mechanism of Action

Inhibits stimulation of  $\beta_1$  receptors mainly in the heart, which decreases cardiac excitability, cardiac output, and myocardial oxygen demand. Esmolol also decreases renin release from kidneys, which helps reduce blood pressure.

## Incompatibilities

Don't mix esmolol with 5% sodium bicarbonate injection because it will limit stability or administer with furosemide because precipitation will form.

## Contraindications

Cardiogenic shock; decompensated heart failure; hypersensitivity to esmolol, other beta blockers and their components; I.V. administration of cardiodepressant calcium-channel antagonists (i.e., verapamil) and esmolol close together while cardiac effects from other drug are still present; pulmonary hypertension; second- or third-degree heart block; severe sinus bradycardia; sick sinus syndrome

## Interactions

### DRUGS

*anticholinesterases such as mivacurium, succinylcholine:*  
Prolonged clinical duration and recovery of mivacurium

and prolonged duration of succinylcholine-induced neuromuscular blockage

*calcium channel antagonists*: Increased risk of fatal cardiac arrest in patients with depressed myocardial function

*clonidine, guanfacine, moxonidine*: Increased risk of withdrawal rebound hypertension

*digitalis glycosides*: Increased risk of bradycardia

*positive inotropic and vasoconstrictive agents such as dopamine, epinephrine, or norepinephrine*: Increased risk of reducing cardiac contractility in presence of high systemic resistance

*sympathomimetics that have beta-adrenergic agonist activity*: May counter effects of esmolol

## Adverse Reactions

**CNS**: Anxiety, confusion, depression, dizziness, fatigue, fever, headache, syncope

**CV**: **Bradycardia**, chest pain, decreased peripheral circulation, **heart block**, **hypotension**

**GI**: Nausea, vomiting

**RESP**: Dyspnea, wheezing

**SKIN**: Diaphoresis, flushing, pallor

**Other**: Infusion-site pain, redness, and swelling

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal bradycardia if given during the last trimester of pregnancy.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LABOR & DELIVERY**

- Drug may cause fetal bradycardia if given during labor and delivery, which may continue after drug is discontinued.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## **Nursing Considerations**

- Use esmolol cautiously if patient has supraventricular arrhythmias with decreased cardiac output, hypotension, or other hemodynamic compromise or is taking drugs that decrease contractility, impulse generation, myocardial filling, or peripheral resistance.
- Also use drug cautiously in patients with impaired renal function because drug is excreted by the kidneys. Patients with end-stage renal disease have an increased risk of adverse reactions.
- Be aware that esmolol should not be given for intraoperative or postoperative hypertension caused by hypothermia-induced vasoconstriction.
- Expect to give lowest possible dose to patients with allergies, asthma, bronchitis, or emphysema. If patient develops bronchospasm, expect to discontinue infusion immediately and give a beta<sub>2</sub>-stimulating drug, as ordered.
- Know that esmolol injection is available in a premixed bag and ready-to-use vial. Do not remove premixed bag from overwrap until ready to use. Tear overwrap at notch and remove premixed bag. Some opacity of the plastic due to moisture absorption during the sterilization process may be observed and will diminish gradually. This is normal and does not affect

the solution quality or safety. Check for minute leaks by squeezing the inner bag firmly. If a leak is present, discard. Solution should be colorless to light yellow and the seal intact. When using the premixed bag, use the medication port solely for withdrawing an initial bolus from the bag. Do not add any additional drugs to the bag. The ready-to-use vial may be used to administer a loading dose by hand-held syringe while the maintenance infusion is being prepared. Once drug has been withdrawn from the ready-to-use bag, the bag should be used within 24 hours, with any unused portion discarded. Do not use plastic containers in series connections when administering because this could result in an embolism due to residual air being drawn from the primary container before administration of the fluid from the secondary container is complete.

- Monitor blood pressure and heart rate often during therapy. Hypotension can occur at any dose but usually is dose related. It typically reverses within 30 minutes after dose is decreased or infusion stopped.
- Inspect site often for thrombophlebitis (pain, redness, swelling at site). Infusion of 20 mg/ml is more likely to cause serious vein irritation than 10 mg/ml. Extravasation of 20 mg/ml may cause a serious local reaction and skin necrosis. Don't give more than 10 mg/ml into a small vein or using a butterfly catheter.

## **PATIENT TEACHING**

- Urge patient to report adverse reactions immediately.
- Reassure patient that his blood pressure, heart rate, and response to therapy will be monitored throughout esmolol therapy.

**esomeprazole magnesium**

**Nexium, Nexium 24 HR**

**esomeprazole sodium**

**Nexium I.V.**

**esomeprazole strontium**

## Class and Category

*Pharmacologic class:* Proton pump inhibitor

*Therapeutic class:* Antiulcerative

## Indications and Dosages

- *To treat symptomatic gastroesophageal reflux disease (GERD)*

### **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION (NEXIUM)**

**Adults.** 20 mg daily for 4 wk.

**Adolescents ages 12 to 17.** 20 mg once daily for 4 wk.

**Children ages 1 to 11.** 10 mg once daily for up to 8 wk.

### **DELAYED-RELEASE CAPSULES (ESOMEPRAZOLE STRONTIUM)**

**Adults.** 24.65 mg once daily for 4 wk.

- *To promote healing of erosive esophagitis in patient with GERD*

### **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION (NEXIUM)**

**Adults.** 20 or 40 mg once daily for 4 to 8 wk, with cycle repeated once more if healing has not taken place after first 8 wk. *Maintenance:* 20 mg once daily for up to 6 months.

**Adolescents ages 12 to 17.** 20 or 40 mg once daily for 4 to 8 wk.

**Children ages 1 to 11 weighing 20 kg(44 lb) or more.** 10 or 20 mg once daily for 8 wk.

**Children ages 1 to 11 weighing less than 20 kg (44 lb).** 10 mg once daily for 8 wk.

**Infants age 1 month to less than 1 year weighing 7.5 (16.5 lb)to 12 kg (26.4 lb).** 10 mg once daily for up to 6 wk.

**Infants age 1 month to less than 1 year weighing 5 kg (11 lb) to 7.5 kg (16.5 lb).** 5 mg once daily for up to 6 wk.

**Infants age 1 month to less than 1 year weighing 3 kg (6.6 lb)to 5 kg (11 lb).** 2.5 mg once daily for up to 6 wk.

## **DELAYED-RELEASE CAPSULES (ESOMEPRAZOLE STRONTIUM)**

**Adults.** 24.65 or 49.3 mg once daily for 4 to 8 wk, with cycle repeated once more if healing has not taken place after first 8 wk. *Maintenance:* 24.65 mg once daily for up to 6 months.

➤ *To treat GERD in a patient with erosive esophagitis who can't take the drug by mouth*

## **I.V. INJECTION**

**Adults.** 20 or 40 mg daily up to 10 days injected over no less than 3 min with switch to oral therapy as soon as possible.

## **I.V. INFUSION**

**Adults.** 20 or 40 mg daily up to 10 days infused over 10 to 30 min with switch to oral therapy as soon as possible.

**Children ages 1 to 17 weighing 55 kg (121 lb) or more.** 20 mg daily up to 10 days infused over 10 to 30 min with switch to oral therapy as soon as possible.

**Children ages 1 to 17 weighing less than 55 kg (121 lb).** 10 mg daily up to 10 days infused over 10 to 30 min with switch to oral therapy as soon as possible.

**Children ages 1 month to less than 1 year.** 0.5 mg/kg daily up to 10 days infused over 10 to 30 min with switch to oral therapy as soon as possible.

***DOSAGE ADJUSTMENT*** For adult patient with severe liver impairment, dosage should not exceed 20 mg daily.

- *As adjunct to treat duodenal ulcer associated with Helicobacter pylori*

### **DELAYED-RELEASE CAPSULES (NEXIUM), DELAYED-RELEASE SUSPENSION (NEXIUM)**

**Adults.** 40 mg daily with amoxicillin 1,000 mg twice a day and clarithromycin 500 mg twice a day for 10 days.

### **DELAYED-RELEASE CAPSULES (ESOMEPRAZOLE STRONTIUM)**

**Adults.** 49.3 mg once daily with amoxicillin 1,000 mg twice daily and clarithromycin 500 mg twice daily for 10 days.

- *To reduce the risk of gastric ulcer formation in patients who are receiving continuous NSAID therapy and who either are over age 60 or have a history of gastric ulcer*

### **DELAYED-RELEASE CAPSULES (NEXIUM), DELAYED-RELEASE SUSPENSION (NEXIUM)**

**Adults.** 20 or 40 mg daily for up to 6 months.

### **DELAYED-RELEASE CAPSULES (ESOMEPRAZOLE STRONTIUM)**

**Adults.** 24.65 or 49.3 mg once daily for up to 6 months.

- *To treat pathological hypersecretory conditions, including Zollinger-Ellison syndrome*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION**

**Adults.** 40 mg twice daily.

***DOSAGE ADJUSTMENT*** For patients with severe hepatic insufficiency, maximum 20 mg daily.

## **DELAYED-RELEASE CAPSULES (ESOMEPRAZOLE STRONTIUM)**

**Adults.** 49.3 mg twice daily.

- *To reduce risk of rebleeding of duodenal or gastric ulcers following therapeutic endoscopy for acute-bleeding duodenal or gastric ulcers*

## **I.V. INFUSION**

**Adults.** 80 mg over 30 min followed by 8 mg per hour for 71.5 hr after initial 30-min dose is completed.

***DOSAGE ADJUSTMENT*** For patients with mild to moderate liver impairment, maximum continuous infusion should not exceed 6 mg/hr; for patients with severe liver impairment, maximum continuous infusion should not exceed 4 mg/hr.

## **Mechanism of Action**

Interferes with gastric acid secretion by inhibiting the hydrogen-potassium-adenosine triphosphatase ( $H^+-K^+-ATPase$ ) enzyme system, or proton pump, in gastric parietal cells. Normally, the proton pump uses energy from hydrolysis of ATPase to drive  $H^+$  and chloride ( $Cl^-$ ) out of parietal cells and into the stomach lumen in exchange for potassium ( $K^+$ ), which leaves the stomach lumen and

enters parietal cells. After this exchange,  $H^+$  and  $Cl^-$  combine in the stomach to form hydrochloric acid (HCl). Esomeprazole irreversibly inhibits the final step in gastric acid production by blocking exchange of intracellular  $H^+$  and extracellular  $K^+$ , thus preventing  $H^+$  from entering the stomach and additional HCl from forming.

## Incompatibilities

Don't give esomeprazole with any other drug through the same I.V. site or tubing.

## Contraindications

Concurrent therapy with rilpivirine-containing products, hypersensitivity to esomeprazole, substituted benzimidazoles, or their components

## Interactions

### DRUGS

*atazanavir, dasatinib, erlotinib, ketoconazole, iron salts, itraconazole, mycophenolate mofetil, nelfinavir nilotinib,*

*rilpivirine:* Decreased blood levels of these drugs

*cilostazol:* Possibly increased blood cilostazol levels

*citalopram:* Increased exposure of citalopram leading to an increased risk of QT prolongation

*clopidogrel:* Reduced effectiveness of clopidogrel

*digoxin:* Possibly increased risk of digoxin toxicity

*methotrexate:* Increased risk of methotrexate toxicities

*rifampin, St. John's wort:* Decreased blood esomeprazole level

*saquinavir:* Increased plasma saquinavir level with increased toxicity

*tacrolimus*: Increased serum tacrolimus level

*voriconazole*: Increased esomeprazole exposure and risk of adverse effects

*warfarin*: Possibly increased INR and PT, leading to abnormal bleeding

## **FOODS**

*all foods*: Decreased bioavailability of esomeprazole

## **Adverse Reactions**

**CNS**: Agitation, aggression, depression, dizziness, fever, headache, hallucinations, **hepatic encephalopathy**, vertigo

**EENT**: Blurred vision, dry mouth, mucosal discoloration, sinusitis, stomatitis, taste disturbance

**ENDO**: Gynecomastia

**GI**: Abdominal pain; Barrett's esophagus; benign polyps or nodules; candidiasis; **Clostridium difficile-associated diarrhea**; constipation; diarrhea; duodenitis; dyspepsia; esophagitis; esophageal stricture, ulceration, or varices; flatulence; fundic gland polyps; gastric ulcer; gastritis; **hepatic failure**; **hepatitis**; jaundice; microscopic colitis; nausea; **pancreatitis**

**GU**: Interstitial nephritis

**HEME**: **Agranulocytosis**, **pancytopenia**

**MS**: Bone fracture, muscle weakness, myalgia

**RESP**: **Bronchospasm**, cough, respiratory tract infection

**SKIN**: Alopecia, cutaneous lupus erythematosus, diaphoresis, **erythema multiforme**, photosensitivity,

pruritus, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other:** **Anaphylaxis**, cyanocobalamin deficiency (prolonged use), **hypocalcemia**, **hypokalemia**, **hypomagnesemia**, infusion-site reactions (erythema, inflammation, phlebitis, pruritus, swelling), systemic lupus erythematosus, vitamin B<sub>12</sub> deficiency

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug may be present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Give oral esomeprazole at least 1 hour before meals because food decreases bioavailability.
- Use delayed-release capsules or oral suspension specific for nasogastric tube administration and delayed-release oral suspension specific for nasogastric or gastric tube administration when administering esomeprazole to a patient with a nasogastric or gastric tube.

**WARNING** Be aware that if patient takes drug with amoxicillin or clarithromycin for *H. pylori*-related ulcer, severe diarrhea may indicate pseudomembranous colitis. Obtain stool cultures, as ordered.

- Always flush I.V. line with normal saline solution injection, lactated Ringer's injection, or 5% dextrose injection before and after giving esomeprazole intravenously.
- For I.V. injection used to treat GERD in patients who cannot take oral esomeprazole, reconstitute powder with 5 ml of normal saline solution injection and give as a bolus dose over 3 or more minutes. Once reconstituted, drug may be stored at room temperature for up to 12 hours.
- For I.V. infusion for adults treated for GERD and unable to take esomeprazole by mouth, reconstitute powder with 5 ml of normal saline solution injection, lactated Ringer's injection, or 5% dextrose injection. Further dilute reconstituted solution to make a final volume of 50 ml, and infuse over 10 to 30 minutes. Reconstituted drug may be stored at room temperature up to 6 hours if mixed with 5% dextrose injection or up to 12 hours if mixed with normal saline solution or lactated Ringer's injection.
- For I.V. infusion for children treated for GERD who are unable to take esomeprazole by mouth, reconstitute powder with 5 ml of 0.9% sodium chloride injection. Further dilute reconstituted solution with 0.9% sodium chloride injection to make final volume of 50 ml. Using a 40-mg vial, the final concentration will be 0.8 mg/ml. Using a 20-mg vial, the final concentration will be 0.4 mg/ml. Infuse over 10 to 30 minutes. Reconstituted drug may be stored at room temperature for up to 12 hours.
- For I.V. infusion used for adults to reduce risk of rebleeding of duodenal or gastric ulcers following therapeutic endoscopy, prepare the loading dose of 80 mg by reconstituting two 40-mg vials. Reconstitute each vial with 5 ml of 0.9% sodium chloride injection, then further dilute the contents of the two vials in 100 ml of 0.9% sodium chloride injection. Administer over 30 minutes. Prepare the continuous infusion in the same manner but administer over 71.5 hours at a rate of 8 mg/hr or decrease rate to 6 mg/hr for mild to moderate liver impairment and to 4 mg/hr for severe liver impairment, as ordered.
- Be aware that patient receiving I.V. esomeprazole should be switched to oral form as soon as possible.
- Monitor patients for bone fractures, especially in patients who are receiving multiple daily doses for a year or longer as proton pump inhibitors such as esomeprazole have been associated with an increased risk for osteoporosis-related fractures of the hip, spine, or wrist.
- Monitor patient's magnesium level, as ordered, because hypomagnesemia may occur with esomeprazole therapy that has lasted longer than 3 months, although most cases have occurred after therapy had been given for more than a year. Notify prescriber if magnesium level drops below normal as hypomagnesemia may cause tetany, arrhythmias, and seizures.

Expect patient to receive magnesium replacement and esomeprazole to be discontinued.

- Be aware that esomeprazole therapy may need to be temporarily halted for at least 14 days if patient is undergoing testing for neuroendocrine tumors because drug may cause false positive results in diagnostic testing.
- Monitor patient for diarrhea, because esomeprazole therapy may increase the risk of *Clostridium difficile*-associated diarrhea. Know that the lowest dose possible for the shortest amount of time should be used to decrease this risk. If diarrhea occurs, expect to obtain a stool specimen to determine if diarrhea is *C. difficile* so that it may be treated appropriately.
- Monitor patient for signs and symptoms of cutaneous and systemic lupus erythematosus or exacerbation of these conditions if already present. Notify prescriber if present and expect serological testing to be done. If results are positive, expect drug to be discontinued. Symptoms are usually relieved in most patients within 4 to 12 weeks.
- Be aware that patients who take esomeprazole long term, especially after 1 year, are at increased risk for developing fundic gland polyps.

## PATIENT TEACHING

- Inform patient that drug should be taken at the lowest dose possible and for the shortest time to decrease risk of adverse effects. Tell him he should never increase dosage or take it long term without consulting prescriber.
- Tell patient that if he has trouble swallowing esomeprazole capsules, tell him to open capsule and sprinkle pellets into a tablespoon of cool applesauce. Tell him not to chew pellets and to discard any unused pellets.
- Remind patient that esomeprazole, including the over-the-counter preparation, is not intended for immediate relief of heartburn; the drug may take up to 4 days before the full effect is experienced.
- Instruct patient to seek immediate medical attention if he experiences an allergic reaction to esomeprazole.
- Urge patient to tell prescriber if he takes antacids or any other OTC or prescription drug.
- Advise patient to contact prescriber if he develops abdominal pain, diarrhea, and fever that does not improve, especially if he has recently taken or is taking an antibiotic. Also advise patient to report any other

persistent or serious signs and symptoms that occur while taking esomeprazole. Instruct patient to stop taking drug if he develops joint pain or rash and to see his doctor for an evaluation of these symptoms.

- Advise patient that drug may increase risk for osteoporosis-related fractures of the hip, spine, or wrist. Instruct him to take fall precautions and have bone health evaluated regularly.

## estazolam

### Class, Category, and Schedule

*Pharmacologic class:* Benzodiazepine

*Therapeutic class:* Sedative-hypnotic

*Controlled substance schedule:* IV

### Indications and Dosages

➤ *To treat insomnia short-term*

#### **TABLETS**

**Adults.** 1 to 2 mg at bedtime.

**Elderly adults.** 1 mg at bedtime.

***DOSAGE ADJUSTMENT*** Starting dose 0.5 mg for small or debilitated elderly patients.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	6-8 hr

### Mechanism of Action

May potentiate effects of gamma-amino-butyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptors in limbic and cortical areas of CNS. By binding to these receptors, estazolam increases GABA's inhibitory effects and blocks cortical and limbic arousal.

## **Contraindications**

Concurrent therapy with itraconazole or ketoconazole; hypersensitivity to estazolam, other benzodiazepines, or their components; pregnancy

## **Interactions**

### **DRUGS**

*anticonvulsants, antihistamines, barbiturates, CNS depressants, MAO inhibitors, narcotics, phenothiazines, psychotropics:* Possibly potentiated action of estazolam  
*barbiturates, carbamazepine, phenytoin, rifampin:* Possibly decreased estazolam level  
*cimetidine, diltiazem, fluvoxamine, isoniazid, itraconazole, ketoconazole, nefazodone, selected macrolide antibiotics:* Possibly increased blood level and impaired hepatic metabolism of estazolam  
*opioids:* Possibly significant respiratory depression and sedation

### **ACTIVITIES**

*alcohol use:* Possibly potentiated CNS depression, including respiratory depression and sedation  
*smoking:* Increased clearance of estazolam

# Adverse Reactions

**CNS:** Amnesia, anxiety, ataxia, confusion, delusions, depression, dizziness, drowsiness, euphoria, headache, hypokinesia, irritability, malaise, nervousness, slurred speech, tremor

**CV:** Chest pain, palpitations, tachycardia

**EENT:** Blurred vision, dry mouth, increased salivation, photophobia

**GI:** Abdominal pain, constipation, diarrhea, nausea, thirst, vomiting

**GU:** Libido changes

**RESP:** **Respiratory depression**

**SKIN:** Diaphoresis

**Other:** Physical or psychological dependence

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Drug is contraindicated in pregnant women.
- Be aware that if mother takes drug prior to delivery, neonate may experience withdrawal symptoms during the postnatal period.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding should not be undertaken during drug therapy.

# Nursing Considerations

- Use estazolam with extreme caution in patients with a history of alcohol or drug abuse because of risk of addiction. Expect to give drug for no more than 12 weeks.
- Use cautiously in debilitated or elderly patients and those with depression or impaired hepatic, renal, or respiratory function.
- Expect to stop drug gradually to prevent withdrawal symptoms. Avoid stopping abruptly if patient has history of seizures.
- Monitor respiratory status, especially in patients with respiratory compromise, who are at increased risk for respiratory depression.
- Be aware that if patient takes estazolam for depression, watch for suicidal tendencies, especially when therapy starts or dosage changes.

## PATIENT TEACHING

- Warn patient not to exceed prescribed time because of risk of addiction.
- Advise patient to avoid hazardous activities until CNS effects of the drug are known.
- Advise patient not to drink alcohol or take other CNS depressants during therapy because of the risk of additive effects.
- Warn debilitated or elderly patients and those with impaired hepatic or renal function about risk of excessive sedation or mental impairment and need to report them.
- Tell patient that if he takes 2-mg dosage for a long time, he should not stop drug abruptly.

## estradiol

**Divigel 1%, Estrace, Estrasorb, Estring, Estrogel, Evamist, Imvexxy, Vagifem**

## estradiol acetate

**Femring, Femtrace**

## estradiol cypionate

**Depo-Estradiol**

## estradiol transdermal system

**Alora, Climara, Estraderm, Estrasorb, Estrogel, Menostar, Minivelle, Vivelle, Vivelle-Dot**

## estradiol valerate

**Delestrogen, Femogex (CAN)**

### **Class and Category**

*Pharmacologic class:* Estrogen

*Therapeutic class:* Hormone

### **Indications and Dosages**

➤ *To treat menopausal symptoms*

#### **TABLETS (ESTRADIOL)**

**Adult menopausal and postmenopausal women.** *Initial:* 0.45 mg daily. May be increased to 0.9 mg daily and then to 1.8 mg daily, as needed.

## **VAGINAL RING (ESTRADIOL ACETATE [FEMRING])**

**Adult women.** One ring (0.05 or 0.1 mg of estradiol/24 hr) inserted into upper third of vaginal vault and replaced every 3 months.

## **TABLETS (ESTRADIOL ACETATE [FEMTRACE])**

**Adult menopausal and postmenopausal women.** *Initial:* 0.45 mg daily. May be increased to 0.9 mg daily and then 1.8 mg daily as needed.

***DOSAGE ADJUSTMENT*** Dosage may be reduced to less than 1 mg daily for patients with only vaginal or vulvar symptoms.

## **I.M. INJECTION (ESTRADIOL CYPIONATE IN OIL)**

**Adult women.** 1 to 5 mg as a single dose every 3 to 4 wk as needed.

## **I.M. INJECTION (ESTRADIOL VALERATE IN OIL)**

**Adult women.** 10 to 20 mg every 4 wk as needed.

## **TRANSDERMAL (ALORA, ESTRADERM, VIVELLE, VIVELLE-DOT)**

**Adult menopausal and postmenopausal women.** *Initial:* 0.025 to 0.05 mg daily if uterus is not present or in cycles of 3 wk on, 1 wk off if uterus is intact and Alora is prescribed. One patch applied to trunk or buttocks and replaced twice/wk (every 3 to 4 days). Adjust dosage to control symptoms, as prescribed.

## **TRANSDERMAL (CLIMARA)**

**Adult women.** *Initial:* 0.025 mg daily. One patch applied to trunk or buttocks, replaced every wk. Titrate dosage to control symptoms, as prescribed. Schedule will be cyclic unless patient has had a hysterectomy.

## **TRANSDERMAL (ESTRASORB)**

**Adult women.** 3.48 g daily in morning. Half of dose (1 pouchful) applied to one thigh and rubbed over entire thigh and calf for 3 min, repeated with second half of dose (1 pouchful) on other thigh and calf.

## **TRANSDERMAL (ESTROGEL)**

**Adult women.** 1.25 g daily applied in thin layer from wrist to shoulder on inside and outside of one arm.

## **TRANSDERMAL MIST (EVAMIST)**

**Adult women.** *Initial:* 1.53 mg (1 spray) once daily in the morning. Dosage may be increased to 3.06 mg (2 sprays) once daily in the morning and then to 4.59 mg (3 sprays) once daily in the morning as needed.

➤ *To treat postmenopausal vaginal and urogenital symptoms*

## **VAGINAL CREAM (ESTRACE)**

**Adult women.** *Initial:* 2 to 4 g (200 to 400 mcg) daily for 1 to 2 wk. Then, dosage gradually reduced to half of initial dose, as prescribed, for 1 to 2 wk. *Maintenance:* 1 g (100 mcg) daily 1 to 3 times/wk for 3 wk, followed by 1 wk of no drugs. Repeat cyclically as needed.

## **VAGINAL RING (ESTRING)**

**Adult women.** One ring (7.5 mcg of estradiol/24 hr) inserted into upper third of vaginal vault and replaced every 3 months.

## **VAGINAL RING (FEMRING)**

**Adult women.** One ring (0.05 or 0.1 mg of estradiol/24 hr) inserted into upper third of vaginal vault and replaced every 3 months.

## **INTRA VAGINAL TABLETS (VAGIFEM)**

**Adult women. Initial:** 10-mcg insert daily for 2 wk, followed by 1 insert twice weekly. Dosage increased to 25 mcg, as needed.

➤ *To treat moderate to severe dyspareunia*

## **VAGINAL INSERT (IMVEXXY)**

**Adult women. Initial:** 4 mcg (1 insert) daily for 2 wk, followed by 4 mcg (1 insert) twice weekly. Dosage increased to 10 mcg (1 insert), as needed.

➤ *To treat moderate to severe vasomotor symptoms*

## **TRANSDERMAL (MINIVELLE)**

**Adult women.** 0.0375 mg daily continuously. Patch replaced twice weekly.

## **GEL (DIVIGEL 1%)**

**Adult women. Initial:** 0.25 mg once daily to skin of left or right upper thigh and then dosage increased, as needed.

➤ *To prevent osteoporosis secondary to estrogen deficiency due to either natural or surgical menopause*

## **TABLETS (ESTRADIOL)**

**Adult women.** At least 0.5 mg daily cyclically or continuously, adjusted as needed to control concurrent menopausal symptoms, as prescribed.

## **TRANSDERMAL (ALORA, MINIVELLE, VIVELLE-DOT)**

**Adult women.** Initial: 0.025 mg daily continuously. One patch applied to lower abdomen or buttocks and replaced twice/wk. Adjust dosage to control symptoms and maintain bone density, as prescribed.

## **TRANSDERMAL (CLIMARA)**

**Adult women.** *Initial:* 0.025 mg daily. One patch applied to trunk or buttocks and replaced every wk. Adjust dosage to control symptoms, as prescribed. Follow a cyclic schedule, as prescribed, unless patient has had a hysterectomy.

## **TRANSDERMAL (MENOSTAR)**

**Adult women.** *Initial:* 0.014 mg daily. One patch applied to lower abdomen and replaced every wk. Follow a cyclic schedule, as prescribed, unless patient has had a hysterectomy.

➤ *To treat estrogen deficiency due to oophorectomy, primary ovarian failure, or female hypogonadism*

## **TABLETS (ESTRADIOL)**

**Adult women.** 0.5 to 2 mg daily continuously or in cycles of 3 wk on, 1 wk off.

## **I.M. INJECTION (ESTRADIOL CYPIONATE IN OIL)**

**Adult women.** 1.5 to 2 mg every month (for female hypogonadism only).

## **I.M. INJECTION (ESTRADIOL VALERATE IN OIL)**

**Adult women.** 10 to 20 mg every month as needed.

## **TRANSDERMAL (ALORA, ESTRADERM, VIVELLE)**

**Adult women.** *Initial:* 0.025 mg daily. One patch applied to trunk or buttocks and replaced twice/wk. Titrate dosage to control symptoms, as prescribed. Follow a cyclic schedule, as prescribed, unless patient has had a hysterectomy.

## **TRANSDERMAL (CLIMARA)**

**Adult women.** *Initial:* 0.05 mg daily. One patch applied to trunk or buttocks and replaced every wk. Adjust dosage to control symptoms, as prescribed. Follow a cyclic schedule, as prescribed, unless patient has had a hysterectomy.

- *To provide palliative treatment for inoperable, progressive breast cancer in selected men and postmenopausal women*

## **TABLETS (ESTRADIOL)**

**Adults.** 10 mg 3 times daily for at least 3 months.

## **TABLETS (ETHINYL ESTRADIOL)**

**Adults.** 1 mg 3 times daily for at least 3 months.

- *To treat advancing, inoperable prostate cancer*

## **TABLETS (ESTRADIOL)**

**Adult men.** 1 to 2 mg or 3 times daily, adjusted or continued, as prescribed, according to patient response.

## **I.M. INJECTION (ESTRADIOL VALERATE)**

**Adult men.** 30 mg every 1 to 2 wk, adjusted or continued, as prescribed, according to patient response.

## **Mechanism of Action**

Increases the rate of DNA and RNA synthesis in cells of female reproductive organs, pituitary gland, hypothalamus, and other target organs. In the hypothalamus, estrogens reduce release of gonadotropin-releasing hormone, which decreases pituitary release of follicle-stimulating hormone and luteinizing hormone. In women, these hormones are required for normal genitourinary and other essential body functions.

At the cellular level, estrogens increase cervical secretions, cause endometrial cell proliferation, and improve uterine tone. Estrogen replacement helps maintain genitourinary function and reduces vasomotor symptoms when estrogen production declines as a result of menopause, surgical removal of ovaries, or other estrogen deficiency states. Estrogen replacement also helps prevent osteoporosis by inhibiting bone resorption.

In men, estrogens inhibit pituitary secretion of luteinizing hormone and decrease testicular secretion of testosterone. These actions may decrease prostate tumor growth and lower the level of prostate-specific antigen (PSA).

## **Contraindications**

Active deep vein thrombosis, pulmonary embolism, or history of these conditions; active or recent (within past year) arterial thromboembolic disease, such as MI or stroke; hepatic dysfunction or disease; history of anaphylactic reaction or angioedema to estradiol; history of jaundice with previous oral contraceptive use; hypersensitivity to estradiol, ethinyl estradiol, or their

components; hypersensitivity to tartrazine dye (contained in 0.02-mg estradiol and ethinyl estradiol tablets); known or suspected breast cancer or history of breast cancer except in appropriately selected patients being treated for metastatic disease; known or suspected estrogen-dependent cancer; known protein C, protein S, or antithrombin deficiency, or other known thrombophilic disorders; uncontrolled diabetes mellitus with hypertension or vascular involvement; pregnancy; liver tumors; uncontrolled diabetes mellitus with hypertension or vascular involvement; undiagnosed abnormal genital bleeding

## Interactions

### DRUGS

*aromatase inhibitors*: Possible interference with aromatase inhibitor's effectiveness

*barbiturates, carbamazepine, hydantoins, rifabutin,*

*rifampin*: Possibly reduced activity of estradiol

*corticosteroids*: Increased therapeutic and toxic effects of corticosteroids

*cyclosporine*: Increased risk of hepatotoxicity and nephrotoxicity

*hepatotoxic drugs, such as isoniazid*: Increased risk of hepatitis and hepatotoxicity

*insulin, oral antidiabetic drugs*: Decreased therapeutic effects of these drugs

*tamoxifen*: Possibly decreased therapeutic effects of tamoxifen

*thyroid hormone replacement*: Decreased effectiveness

*warfarin*: Decreased anticoagulant effect

### FOODS

*grapefruit juice*: Decreased estradiol metabolism and possibly increased adverse effects

## ACTIVITIES

*smoking*: Increased risk of pulmonary embolism, stroke, thrombophlebitis, and transient ischemic attack

## Adverse Reactions

**CNS**: Affect liability, chorea, **CVA**, dementia, depression, dizziness, emotional lability, fatigue, headache, insomnia, irritability, malaise, migraine headache, mood swings, nervousness, paresthesia

**CV**: **Deep venous thrombosis**, hypertension, **MI**, palpitations, peripheral edema, **thromboembolism**, thrombophlebitis, **thromboembolism**, **unstable angina**

**EENT**: Intolerance of contact lenses, oral paresthesia, **pharyngeal edema**, retinal vascular thrombosis, swollen lip or tongue, vision changes

**ENDO**: Breast enlargement, pain, tenderness, or **tumors**; **breast cancer**, elevated estrogen levels, fibrocystic breast changes; gynecomastia; hyperglycemia; nipple discharge or nipple and areola discoloration

**GI**: Abdominal cramps or pain, anorexia, bloating, **bowel obstruction** (vaginal ring), cholelithiasis, constipation, diarrhea, elevated liver enzymes, enlargement of abdomen or hepatic hemangiomas, gallbladder disease, **gallbladder obstruction**, **GI hemorrhage**, **hepatitis**, increased appetite, jaundice, nausea, **pancreatitis**, **portal vein thrombosis**, vomiting

**GU**: Amenorrhea, breakthrough bleeding, cervical or vaginal erosion, clear vaginal discharge, decreased libido,

dysmenorrhea, **endometrial hyperplasia or cancer**, genital edema or itching, impotence, increased libido (females), **ovarian cancer**, pelvic pain, **portal vein thrombosis**, prolonged or heavy menstrual bleeding, ring adherence to vaginal wall, testicular atrophy, urinary frequency, uterine leiomyomata, vaginismus, vaginitis, vaginal abrasion or ulceration (ring), vaginal candidiasis or discharge, vulvovagina discomfort (burning sensation, pain, rash, swelling), worsening of endometriosis

**MS:** Arthralgia, leg cramps, muscle spasms

**RESP:** Dyspnea, **pulmonary embolism**

**SKIN:** Acne, alopecia, diaphoresis, discoloration or dry skin, **erythema multiforme**, erythema nodosum, facial pigmentation, hirsutism, melasma, oily skin, pruritus, purpura, rash, seborrhea, urticaria

**Other:** **Angioedema**, application-site reactions (transdermal), folic acid deficiency, **hypercalcemia** (in metastatic bone disease), **hypersensitivity reactions**, **toxic shock syndrome** (vaginal ring), weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Drug is not known to cause fetal harm if inadvertently taken during early pregnancy.
- Drug has no therapeutic use during pregnancy and is contraindicated in pregnancy.

### LACTATION

- Drug decreases the quality and quantity of breast milk.
- Breastfeeding should not be undertaken while mother is receiving drug.

# Nursing Considerations

**WARNING** Be aware that estradiol (Estrace) and ethinyl estradiol (Estinyl) are distinct and separate products and that their dosing isn't equivalent.

- Use estradiol cautiously in patients with asthma, chorea, diabetes mellitus, epilepsy, migraine headaches, porphyria, systemic lupus erythematosus, or hepatic hemangiomas because estradiol may worsen these disorders.
- Administer oral preparations with or immediately after food to decrease nausea.
- For I.M. injection of estradiol cypionate or estradiol valerate, roll vial and syringe between palms to evenly disperse drug. Use at least a 21G needle because of viscosity of oil-based solution. Use a dry, sterile syringe. Inject deep into upper outer quadrant of gluteal muscle. Aspirate before injection to avoid injection into a blood vessel.
- Be aware that if patients are converting from oral estrogen to transdermal system, oral estrogen should be stopped 1 week before skin patches are applied.
- Expect to begin prophylaxis treatment against osteoporosis at the start of menopause.
- Be aware that estrogen therapy should be given cyclically or combined with a progestin for 10 to 14 days per month in women with an intact uterus to minimize the risk of endometrial hyperplasia.

**WARNING** Be aware that severe hypercalcemia may occur in patients with bone metastasis due to breast cancer because estrogens influence the metabolism of calcium and phosphorus. Monitor for toxic effects of increased calcium absorption in patients who are predisposed to hypercalcemia or nephrolithiasis.

**WARNING** Assess patient for possible contact lens intolerance or changes in vision or visual acuity because estrogens can cause keratoconus, leading to increased curvature of the cornea. Be prepared to discontinue drug immediately, as prescribed, if patient experiences

sudden partial or complete loss of vision or sudden onset of diplopia, migraine, or proptosis.

- Monitor PT test results of patients receiving warfarin for loss of anticoagulant effect because estrogens increase production of clotting factors VII, VIII, IX, and X and promote platelet aggregation.
- Watch for elevated liver enzymes because estrogens may worsen such conditions as acute intermittent or variegate hepatic porphyria.
- Closely monitor patient's blood pressure. A few patients may experience a substantial increase in blood pressure as an idiosyncratic reaction to estrogen. Monitor patients who already have hypertension for increases in blood pressure because estrogens may cause fluid retention. Also monitor patients with asthma, heart disease, migraines, renal disease, or seizure disorder for exacerbation of these conditions.
- Watch for peripheral edema or mild weight gain because estrogens can cause sodium and fluid retention.
- Monitor serum glucose level frequently in patients who have diabetes mellitus because estrogens may decrease insulin sensitivity and alter glucose tolerance.

**WARNING** Expect to stop estrogen therapy in any woman who develops signs or symptoms of cancer; cardiovascular disease, such as MI, pulmonary embolism, stroke; dementia; or venous thrombosis.

- Be aware that women at risk for arterial vascular disease include those with diabetes mellitus, hypercholesterolemia, hypertension, obesity, tobacco use, or venous thromboembolism. Know that these factors, if present, should be addressed and brought under control.
- Be aware that exogenous estradiol and progestins may worsen mood disorders, including depression. Monitor patient for anxiety, depression, dizziness, fatigue, insomnia, or mood changes.
- Assess skin for melasma (tan or brown patches), which may develop on forehead, cheeks, temples, and upper lip. These patches may persist after drug is stopped.
- Check patient's triglyceride level routinely because, in patients with hypertriglyceridemia, estrogen therapy may increase serum triglyceride level enough to cause pancreatitis and other complications.

- Monitor serum PSA level in patients with inoperable prostate cancer to determine if patient is responding to hormone therapy. If patient responds (usually within 3 months), expect therapy to continue until disease is significantly advanced.
- Expect to stop estrogen therapy several weeks before patient undergoes major surgery, as prescribed, because certain procedures are associated with prolonged immobilization and therefore pose a risk of thromboembolism.
- Be aware that if patient takes thyroid hormone replacement therapy, monitor her for increased signs and symptoms of hypothyroidism because estradiol may increase thyroid binding globulin levels, which may make the patient's current dose of thyroid hormone insufficient.

**WARNING** Monitor patient closely for signs of anaphylaxis, which may occur any time during therapy and may require emergency medical treatment. Monitor patient with history of hereditary angioedema closely because estradiol may exacerbate symptoms of angioedema.

## PATIENT TEACHING

- Inform patient of risks involved in estrogen therapy before therapy starts. These risks may include increased risk of breast, endometrial, or ovarian cancer; cardiovascular disease; dementia (if age 65 or over); gallbladder disease; and vision abnormalities.
- Advise patient to remain recumbent for at least 30 minutes after applying estradiol vaginal cream. Inform her that she may use a sanitary napkin (but not a tampon) to protect clothing after application.
- Teach patient proper application and use of transdermal patch. Instruct her not to apply patch to breasts, waistline, or other areas where it may not adhere properly. Advise her to rotate application sites at least weekly and to remove old patch before applying new one. If patch falls off, instruct her to reapply it to another area or to apply a new patch and continue the original treatment schedule. Caution her not to expose patch to sun for long periods. Explain that she may bathe while wearing the patch. Instruct patient to discard used patch in household trash in a way that prevents accidental application or ingestion by children, pets, or others.
- Teach patient to apply Estrogel to clean, dry skin of one arm, using applicator. Emphasize importance of transferring all of the gel from

applicator to arm. Tell patient to spread gel as thinly as possible over entire inside and outside of arm from wrist to shoulder. Advise her to wash her hands with soap and water afterward and to avoid fire and smoking until gel has dried because it's flammable. Tell patient never to apply gel to breasts. Warn that gel is alcohol-based and that patient should avoid fire, flame, or smoking until gel has dried.

- Instruct patient to apply Divigel to either the left or right upper thigh once daily, but to rotate to the opposite site on alternating days. Explain that the application surface area should be about 5 to 7 inches (about the size of two palm prints). The entire contents of a unit-dose packet should be applied each day. Remind patient that gel should never be applied to her breasts, face, irritated skin, or in or around her vagina. After application, tell patient to let gel dry before dressing and not to wash the site for 1 hour after application. Instruct patient to wash her hands after applying gel.
- Inform patient that each pouch of Estrasorb contains half of daily dose. Instruct her to apply emulsion to clean, dry skin on top of thigh and to rub it into entire thigh and calf for 3 minutes. Tell her to rub any excess emulsion onto her buttocks. Then, advise her to repeat procedure on her other thigh and calf using the second pouch. Tell her to wash her hands with soap and water after the application and to dress only after affected areas are dry.
- Tell patient using Imvexxy vaginal inserts to insert the smaller end up for a depth of about two inches into the vaginal canal. Each insert should be inserted at about the same time every day.
- Teach patient proper use of estradiol vaginal ring. Instruct her to insert ring in upper third of vagina, to keep it there for 90 days, and then to remove it and insert a new ring. Or she may remove it during the 90-day dosage period, rinse it with lukewarm (not hot or boiling) water, and reinsert it as needed for personal hygiene. Remind patient that she shouldn't be able to feel the ring when it's in place. If she does, she should use a finger to push the ring farther into her vagina. If vaginal wall ulceration or erosion occurs, suggest that patient leave ring out and not replace it until healing is complete to keep ring from adhering to healing tissue.
- Instruct patient using estradiol vaginal ring to remove ring immediately and contact prescriber if she develops fever, nausea, vomiting, diarrhea, muscle pain, dizziness, faintness, or a sunburn rash on face or body that may suggest a rare but serious bacterial infection called toxic shock syndrome. Also urge patient to seek prompt medical care if ring becomes attached to vaginal wall (rare), making removal difficult.
- Instruct patient prescribed transdermal Evamist to prime the pump of a new device before the first dose by holding the container upright with the

cover in place and spraying 3 sprays. Then, to deliver a dose, she should spray the mist on the inner aspect of her forearm starting near the elbow. Instruct her to let the mist dry for 2 minutes and not to wash the area for at least 30 minutes. Warn her that secondary exposure may occur if a child or other adult comes into contact with sprayed area. To avoid this, she should cover the area with clothing after the spray dries.

- Inform patient receiving estradiol treatment that she should have an annual pelvic examination to screen for cervical dysplasia and be followed closely for other types of cancers and disorders associated with estradiol use.
- Tell patient who has an intact uterus and is prescribed transdermal Menostar that she will need to receive progestin for 14 days every 6 to 12 months and have an endometrial biopsy yearly.
- Advise patient that less serious but common side effects of estradiol therapy include abdominal or stomach cramps, bloating, breast pain or tenderness, fluid retention, hair loss, irregular vaginal bleeding or spotting, nausea and vomiting, and vaginal yeast infection.

## **estrogens (conjugated)**

**C.E.S. (CAN), Premarin**

**synthetic estrogens, A  
(conjugated)**

**Cenestin**

**synthetic estrogens, B  
(conjugated)**

**Enjuvia**

# Class and Category

*Pharmacologic class:* Estrogen

*Therapeutic class:* Hormone

## Indications and Dosages

- *To treat moderate to severe vasomotor menopausal symptoms*

### **TABLETS**

**Adults.** 0.3 (C.E.S., Enjuvia, Premarin) or 0.45 mg (Cenestin) daily or cyclically 25 days on, 5 days off (C.E.S, Premarin only). Dosage increased as needed to control symptoms. *Maximum:* 1.25 mg daily.

- *To treat vaginal and vulvar atrophy*

### **TABLETS**

**Adults.** 0.3 mg daily or cyclically 25 days on, 5 days off (Premarin only). Dosage increased as needed to control symptoms.

- *To treat atrophic vaginitis and vaginal and vulvar atrophy*

### **VAGINAL CREAM (PREMARIN)**

**Adults.** 0.5 to 2 g daily in cycles of 3 wk on, 1 wk off.

- *To treat moderate to severe vaginal dryness and pain with intercourse and symptoms of vulvar and vaginal atrophy in menopause*

### **TABLETS (ENJUVIA)**

**Adults.** 0.3 mg daily.

## **VAGINAL CREAM (PREMARIN)**

**Adults.** 0.5 g twice/wk. Or, 0.5 g daily for 21 days followed by 7 days off, with cycle repeated every 28 days.

- *To prevent postmenopausal osteoporosis*

## **TABLETS (PREMARIN)**

**Adults.** 0.3 mg daily continuously or in cycles of 25 days on, 5 days off. Dosage increased as needed to control symptoms.

- *To provide palliative treatment for advanced androgen-dependent prostate cancer*

## **TABLETS (PREMARIN)**

**Adult men.** 1.25 to 2 mg 3 times daily.

- *To provide palliative treatment for metastatic breast cancer*

## **TABLETS (PREMARIN)**

**Adults.** 10 mg 3 times daily for 3 months or longer.

- *To treat dysfunctional uterine bleeding*

## **I.V. INJECTION, I.M. INJECTION (PREMARIN)**

**Adults.** 25 mg, repeated in 6 to 12 hr as needed. I.V. injection preferred route; given slowly.

- *To treat estrogen deficiency from oophorectomy or primary ovarian failure*

## **TABLETS (PREMARIN)**

**Adults.** 1.25 mg daily in cycles of 3 wk on, 1 wk off. Dosage adjusted as needed.

- *To treat female hypogonadism*

## **TABLETS (PREMARIN)**

**Adults.** 0.3 to 0.625 mg daily in cycles of 3 wk on, 1 wk off. Dosage adjusted as needed.

## **Mechanism of Action**

Increase the rate of DNA and RNA synthesis in the cells of female reproductive organs, hypothalamus, pituitary glands, and other target organs. In the hypothalamus, estrogens reduce the release of gonadotropin-releasing hormone, which decreases pituitary release of follicle-stimulating hormone and luteinizing hormone. In women, these hormones are required for normal genitourinary and other essential body functions. At the cellular level, estrogens increase cervical secretions, cause endometrial cell proliferation, and increase uterine tone. Estrogen replacement helps maintain genitourinary function and reduce vasomotor symptoms when estrogen production declines from menopause, surgical removal of ovaries, or other estrogen deficiency. Estrogen also helps prevent osteoporosis by keeping bone resorption from exceeding bone formation.

In men, estrogens inhibit pituitary secretion of luteinizing hormone and decrease testicular secretion of testosterone. These actions may decrease prostate tumor growth and lower the level of prostate-specific antigen.

## **Contraindications**

Active deep vein thrombosis, pulmonary embolism, or history of these conditions; active or recent (within past year) arterial thromboembolic disease such as MI or stroke; history of anaphylactic reaction or angioedema to estradiol; hypersensitivity to estrogens or their components; known

or suspected breast cancer or history of breast cancer; known or suspected estrogen-dependent cancer; known protein C, protein S, or antithrombin deficiency or other known thrombophilic disorders; pregnancy; liver impairment or disease; undiagnosed abnormal genital bleeding

## **Incompatibilities**

Don't combine I.V. estrogens with acid solutions, ascorbic acid, and protein hydrolysate because they're incompatible.

## **Interactions**

### **DRUGS**

*aromatase inhibitors*: Possibly interference with aromatase inhibitor's effectiveness

*barbiturates, carbamazepine, hydantoins, rifabutin, rifampin*: Possibly reduced activity of estrogen and medroxyprogesterone

*corticosteroids*: Increased therapeutic and toxic effects of corticosteroids

*cyclosporine*: Increased risk of hepatotoxicity and nephrotoxicity

*hepatotoxic drugs (such as isoniazid)*: Increased risk of hepatitis and hepatotoxicity

*insulin, oral antidiabetic drugs*: Decreased therapeutic effects of these drugs

*tamoxifen*: Possibly interference with tamoxifen's therapeutic effects

*thyroid hormone replacement*: Decreased effectiveness

*warfarin*: Decreased anticoagulant effect

### **ACTIVITIES**

*smoking*: Increased risk of pulmonary embolism, stroke, thrombophlebitis, and transient ischemic attack

## Adverse Reactions

**CNS:** Asthenia, **CVA**, dementia, depression, dizziness, growth benign meningioma, headache, insomnia, migraine headache, mood disturbance, nervousness, paresthesia

**CV:** **Deep vein thrombosis**, hypertension, **MI**, peripheral edema, **thromboembolism**, thrombophlebitis, vasodilation

**EENT:** Intolerance of contact lenses, pharyngitis, retinal vascular thrombosis, rhinitis, sinusitis

**ENDO:** Breast enlargement, pain, tenderness, or **tumors**; gynecomastia (men); hot flashes; hyperglycemia

**GI:** Abdominal cramps or pain, abdominal distention, anorexia, cholestatic jaundice, constipation, diarrhea, flatulence, gallbladder disease, **gallbladder obstruction**, hepatic hemangioma enlargement, **hepatitis**, increased appetite, **ischemic colitis**, nausea, **pancreatitis**, vomiting

**GU:** Amenorrhea, breakthrough bleeding, cervical erosion, clear vaginal discharge, decreased libido (men), dysmenorrhea, **endometrial cancer** or hyperplasia, impotence, increased libido (women), leukorrhea, **ovarian cancer**, prolonged or heavy menstrual bleeding, testicular atrophy, uterine leiomyomata enlargement, vaginal candidiasis, vaginitis, vaginal-site reactions (vaginal administration only) such as burning, irritation, and genital pruritus

**MS:** Arthralgias, back pain, muscle spasms

**RESP:** Bronchitis, increased cough, **pulmonary embolism**

**SKIN:** Acne, alopecia, chloasma, **erythema multiforme**, erythema nodosum, hemorrhagic eruption, hirsutism, melasma, oily skin, pruritus, purpura, rash, seborrhea, urticaria

**Other:** **Anaphylaxis**, **angioedema**, flu-like syndrome, folic acid deficiency, **hypercalcemia** (in metastatic bone disease), weight gain

## Childbearing Considerations

### PREGNANCY

- Drug is not known to cause fetal harm if inadvertently taken during early pregnancy.
- Drug has no therapeutic use during pregnancy and is contraindicated in pregnancy.

### LACTATION

- Drug decreases the quality and quantity of breast milk.
- Breastfeeding should not be undertaken during drug therapy.

## Nursing Considerations

- Use conjugated estrogens cautiously in patients with severe hypocalcemia because a sudden increase in serum calcium level may cause adverse reactions.
- Reconstitute conjugated estrogens with normal saline solution, dextrose, or invert sugar solution and use within a few hours. Discard solution that contains precipitate.

**WARNING** Monitor serum calcium level to detect severe hypercalcemia in patients with bone metastasis from breast cancer.

**WARNING** Monitor patient closely, especially within minutes to hours of taking first dose, as anaphylaxis may occur, requiring emergency intervention. Be aware that estrogen therapy may exacerbate symptoms of angioedema in women with hereditary angioedema. Monitor for signs of swelling of the face, lips, throat, or tongue, and provide emergency care, as needed.

- Watch for elevated liver enzymes because estrogen and progestins may worsen such conditions as acute intermittent or variegate hepatic porphyria.
- Assess hypertensive patients for increases in blood pressure because estrogens may cause fluid retention.
- Monitor patients with asthma, diabetes mellitus, endometriosis, heart disease, lupus erythematosus, migraine headaches, renal disease, or seizure disorder for worsening of these conditions.
- Assess PT for loss of anticoagulant effects if patient takes warfarin, because estrogens increase production of clotting factors and promote platelet aggregation.
- Expect to stop drug during periods of immobilization, 4 weeks before elective surgery, and if jaundice develops.

**WARNING** Expect to stop estrogen therapy in any woman who develops signs or symptoms of cancer; cardiovascular disease, such as MI, pulmonary embolism, stroke, venous thrombosis; or dementia.

- Check triglyceride level routinely because, in hypertriglyceridemia, estrogen therapy may increase triglycerides enough to cause pancreatitis and other complications.
- Know that if patient takes thyroid hormone replacement therapy, monitor her for increased signs and symptoms of hypothyroidism because estrogen may increase thyroid-binding globulin level, which may make the patient's current dose of thyroid hormone insufficient.
- Be aware that estrogen may worsen mood disorders, including depression. Monitor patient for depression, fatigue, insomnia, or mood changes.

## PATIENT TEACHING

- Explain the risks of estrogen therapy, including increased risk of breast, endometrial, or ovarian cancer; cardiovascular disease; dementia; and gallbladder disease.
- Instruct patient how to use vaginal cream and to cleanse plunger by removing it from barrel and washing it with mild soap and warm water after each use.
- Urge patient to immediately report breakthrough bleeding to prescriber.
- Instruct patient to perform monthly breast self-examination and to comply with all prescribed follow-up examinations.
- Warn female patient that long-term use may increase risk of breast or endometrial cancer, dementia, gallbladder disease, heart disease, and stroke.
- Inform patient that estrogen vaginal cream may alter effectiveness of cervical caps, condoms, or diaphragms made of latex or rubber.
- Instruct patient to notify prescriber if she sees something that resembles a tablet in her stool.

**eszopiclone**

**Lunesta**

## Class, Category, and Schedule

*Pharmacologic class:* Pyrrolopyrazine derivative

*Therapeutic class:* Sedative-hypnotic

*Controlled substance schedule:* IV

## Indications and Dosages

- *To treat insomnia when at least 7 or 8 hours are remaining before the planned time of awakening*

## TABLETS

**Adults.** *Initial:* 1 mg immediately at bedtime. May be increased to 2 or 3 mg at bedtime, as needed. *Maximum:* 3 mg at bedtime.

**DOSAGE ADJUSTMENT** For patients with severe hepatic impairment, patients who take potent CYP3A4 inhibitors, or patients who are debilitated or elderly, dosage should not exceed 2 mg at bedtime. Dosage adjustment may be needed if other CNS depressants are also being taken.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	Unknown

## Mechanism of Action

May potentiate effects of the inhibitory neurotransmitter gamma-aminobutyric acid (GABA) by binding close to or with benzodiazepine receptors in limbic and cortical areas of the CNS. By binding to these receptor sites and areas, eszopiclone increases GABA's inhibitory effects and blocks cortical and limbic arousal, thereby inducing and maintaining sleep.

## Contraindications

Complex sleep behaviors with eszopiclone past administration, hypersensitivity to eszopiclone or its components

## Interactions

## DRUGS

*CYP3A inducers such as rifampin:* Decreased eszopiclone level

*CYP3A inhibitors such as clarithromycin, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, troleandomycin:* Increased eszopiclone level  
other CNS depressants: Possibly additive effects

## ACTIVITIES

*alcohol use:* Additive effect on psychomotor performance

## FOOD

*Heavy, high-fat meal:* Possibly reduced effectiveness of eszopiclone

## Adverse Reactions

**CNS:** Aggressiveness that seems out of character, agitation, anxiety, bizarre behavior such as sleep driving or walking, confusion decreased level of consciousness, depersonalization, depression with possible **suicidal ideation**, dizziness, drowsiness, hallucinations, headache (including migraine), nervousness, neuralgia, next day psychomotor impairment, somnolence, unusual dreams

**CV:** Chest pain, peripheral edema

**EENT:** Dry mouth; smell distortion; **swelling of glottis, larynx, or tongue**; taste perversion

**ENDO:** Gynecomastia

**GI:** Diarrhea, **hepatitis**, indigestion, nausea, vomiting

**GU:** Decreased libido, dysmenorrhea, UTI

**RESP:** **Asthma**, respiratory tract infection

**SKIN:** Pruritus, rash

**Other:** **Angioedema**, generalized pain, **heatstroke**, viral infection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use eszopiclone cautiously in patients with severe mental depression or reduced respiratory function; drug may intensify mental depression and lead to respiratory depression.
- Institute safety and prevention of fall measures because of the adverse CNS effects of the drug.

### PATIENT TEACHING

- Instruct patient not to exceed prescribed eszopiclone dosage and not to stop drug abruptly because withdrawal symptoms may occur.
- Advise patient to take drug immediately before bedtime.
- Warn patient, especially if debilitated or elderly, that drug may impair motor and/or cognitive performance increasing risk of falls. Advise patient

to avoid potentially hazardous activities until drug's CNS effects are known.

- Urge patient to avoid alcohol and CNS depressants because of additive effects.
- Advise woman of childbearing age to notify prescriber if she becomes or intends to become pregnant during therapy.
- Explain that sleep may be disturbed for the first few nights after therapy stops.
- Warn patient and caregiver that some patients have performed bizarre activities after taking drug, such as driving the car, preparing and eating food, making phone calls, or having sex while not fully awake and often with no memory of the event. These episodes usually occur in patients who have taken the drug with alcohol or other CNS depressant, who have taken the drug with less than a full night of sleep remaining (7 to 8 hours), or who have exceeded the recommended dose. If such an episode occurs, the prescriber should be notified and eszopiclone therapy discontinued immediately.

**etanercept**

**Enbrel**

**etanercept-szzs**

**Erelzi**

## **Class and Category**

*Pharmacologic class:* Tumor necrosis factor (TNF) blocker

*Therapeutic class:* Immunosuppressant

## **Indications and Dosages**

- *To reduce signs and symptoms of rheumatoid arthritis, slow structural damage in active arthritis, and improve physical function in patients with rheumatoid arthritis, alone or in combination with methotrexate; to reduce signs and symptoms of active ankylosing spondylitis*

## **SUBCUTANEOUS INJECTION**

**Adults.** 50 mg once/wk on same day each wk. *Maximum:* 50 mg/wk.

- *To treat psoriatic arthritis, alone or in combination with methotrexate*

## **SUBCUTANEOUS INJECTION**

**Adults.** 50 mg once/wk on same day each wk. *Maximum:* 50 mg/wk.

- *To treat chronic moderate-to-severe plaque psoriasis in candidates for systemic therapy or phototherapy*

## **SUBCUTANEOUS INJECTION**

**Adults.** *Initial:* 50 mg twice/wk 3 to 4 days apart for 3 months; then reduced to 50 mg/wk. Alternatively but less common, 25 mg or 50 mg/wk.

## **SUBCUTANEOUS INJECTION**

**Children ages 4 and older weighing 63 kg (138 lb) or more.** 50 mg once/wk on same day each wk.

**Children ages 4 and older weighing less than 63 kg (138 lb).** 0.8 mg/kg/wk.

- *To reduce signs and symptoms of moderately to severely active polyarticular juvenile idiopathic arthritis*

## **SUBCUTANEOUS INJECTION (ENBREL)**

**Children ages 2 to 17 weighing 63 kg (138 lb) or more.** 50 mg once/wk on same day each wk.

**Children ages 2 to 17 weighing less than 63 kg (138 lb).** 0.8 mg/kg/wk. *Maximum:* 50 mg/wk.

## **SUBCUTANEOUS INJECTION (ERELZI)**

**Children ages 2 to 17 weighing 63 kg (138 lb) or more.** 50 mg once/wk on same day each wk.

## **Incompatibilities**

Don't combine etanercept with other drugs.

## **Contraindications**

Hypersensitivity to etanercept or its components, sepsis or risk of it

## **Interactions**

### **DRUGS**

*abatacept:* Increased risk of adverse reactions, especially infections

*cyclophosphamide:* Possibly increased risk of malignancy

*live vaccines:* Possibly increased risk of secondary transmission of infection from live vaccine

*sulfasalazine:* Possibly decreased neutrophil count

## **Adverse Reactions**

**CNS:** Asthenia, chills, demyelination including both central and peripheral nervous systems, dizziness, fever, headache,

multiple sclerosis, paresthesias, **seizures**

**CV:** Chest pain, **congestive heart failure**, hypertension, **hypotension**, peripheral edema, systemic vasculitis

**EENT:** Optic neuritis, pharyngitis, rhinitis, scleritis, sinusitis, uveitis

**GI:** Abdominal abscess or pain, **autoimmune hepatitis**, cholecystitis, diarrhea, elevated liver enzymes, gastroenteritis, indigestion, inflammatory bowel disease, nausea, **noninfectious hepatitis**, **reactivation of hepatitis B**, vomiting

**GU:** Pyelonephritis

**HEME:** Anemia, **aplastic anemia**, **leukemia**, **leukopenia**, lymphadenopathy, **neutropenia**, **pancytopenia**, **thrombocytopenia**

**MS:** Osteomyelitis, septic arthritis, transverse myelitis

**RESP:** Bronchitis, cough, **interstitial lung disease**, pneumonia, upper respiratory tract infection

**SKIN:** Cellulitis, cutaneous lupus erythematosus or vasculitis, **erythema multiforme**, foot abscess, leg ulceration, **melanoma and nonmelanoma skin cancers**, **Merkel cell carcinoma**, new or worsening psoriasis, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Angioedema**; bacterial, fungal, mycobacterial, parasitic, and viral infections; injection-site bruising, edema, erythema, itching, and pain; etanercept-induced antibodies; lymphadenopathy; lupus-like syndrome, **macrophage activation syndrome**, **malignancy, such as lymphoma**; sarcoidosis; **sepsis**

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Safety of administering live or live-attenuated vaccines in infants exposed to drug in utero is unknown.

## LACTATION

- Drug is present in breast milk in low levels.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Screen patient for latent tuberculosis with a tuberculin skin test before starting etanercept therapy. If test is positive, expect to give treatment, as ordered, before starting etanercept. Also screen patient for hepatitis B. If present, expect etanercept therapy to be withdrawn because antirheumatic therapies like etanercept may reactivate hepatitis B.
- Be aware that patients treated with tumor necrosis factor-alpha blockers such as etanercept are at increased risk for developing serious infections due to bacterial (including *Legionella* and *Listeria*), fungal, mycobacterial, parasitic, and viral pathogens. These infections can become life-threatening and involve multiple organ systems. Monitor patient closely throughout therapy.
- Know that tumor necrosis factor antagonists shouldn't be given with etanercept because doing so increases the risk of serious infection.
- Use cautiously in patients with a history of recurrent infection, underlying conditions that may predispose them to infections, or an existing chronic, latent, or localized infection because etanercept increases their risk of infection.
- Use cautiously in patients with COPD, and monitor respiratory status closely because etanercept therapy may increase patient's risk of adverse respiratory reactions.

- Use cautiously in patients with preexisting or recent onset CNS demyelinating disorders because drug may worsen these conditions. Also use cautiously in patients with heart failure or who have a history of serious hematologic abnormalities because drug may worsen these conditions.

**WARNING** Don't use the diluent provided with the Enbrel brand of etanercept (bacteriostatic water for injection, USP, with 0.9% benzyl alcohol) for patients who have benzyl alcohol hypersensitivity. Instead, use sterile water for injection for these patients.

**WARNING** Avoid handling needle cover of diluent syringe for Enbrel brand of drug, the needle cover within the white cap of the SureClick autoinjector, or inside the purple cap of the Enbrel Mini cartridge if latex allergy is present because these components contain dry natural rubber.

## Mechanism of Action

Etanercept reduces joint inflammation from rheumatoid arthritis by binding with tumor necrosis factor (TNF), a cytokine, or protein that plays an important role in normal inflammatory and immune responses.

In rheumatoid arthritis, the immune and inflammatory process triggers release of TNF, mainly from macrophages. TNF then binds to TNF receptors on cell membranes, as shown below left. This action renders TNF biologically active and triggers a cascade of inflammatory events that results in increased inflammation of the synovial membrane, release of destructive lysosomal enzymes, and further joint destruction.

Etanercept binds to TNF and prevents it from binding with TNF receptors on the cell membranes, as shown below right. This action renders bound TNF biologically inactive, prevents TNF-mediated cellular responses, and significantly reduces inflammatory activity.

Description

- Know that when giving the Enbrel brand of etanercept to children, don't use the 25-mg prefilled syringe if the child weighs less than 31 kg (68 lb). The 50-mg prefilled syringe or SureClick autoinjector may be used for children who weigh 63 kg (138 lb) or more.
- Know that when giving the Erelzi brand of etanercept using the single-dose prefilled syringe or single-dose prefilled Sensorready pen, it is important to leave drug at room temperature for 15 to 30 minutes before injecting. Do not remove the needle cover while allowing the prefilled syringe to reach room temperature. Be aware that it is normal for small white particles of protein to be present in the solution but that the solution should not be discolored, cloudy, or contain foreign particulate matter.

**WARNING** Expect to stop etanercept if patient develops sepsis.

- Avoid giving live-virus vaccines to patients who are taking etanercept because drug decreases immune response and increases risk of secondary transmission of vaccine virus. Ensure that children are up to date on immunizations prior to etanercept being initiated.
- Monitor immunosuppressed patients for evidence of acute or chronic infection, including chills, fever, and tachycardia, because etanercept decreases defenses against infection. It also increases the risk of developing malignant tumors.
- Continue giving corticosteroids, NSAIDs, and other analgesics, as prescribed, during etanercept therapy.
- Be aware that malignancies, especially leukemias and lymphomas, have been reported rarely in patients taking tumor necrosis factor blockers such as etanercept. Children, adolescents, and patients with rheumatoid arthritis, especially those with very active disease, are at greatest risk. Monitor closely.

## **PATIENT TEACHING**

- Reassure patient or caregiver that other medications such as analgesics, NSAIDs, and steroid therapy may be continued while patient is receiving etanercept.
- Inform patient that etanercept is given by a small injection into the skin, and teach him proper injection technique if needed.
- Tell patient that a prefilled syringe or pen, depending on brand used, is available if the dose prescribed is 50 mg.
- Tell patient that if he will take less than a 50-mg dose or prefers not to use prefilled syringe, he will need to use the Enbrel brand. In this case, advise him to use drug as soon as possible after dissolving powder. Dissolved powder may be kept in refrigerator for up to 6 hours after mixing and then should be discarded.
- Alert patient using Enbrel brand of drug and SureClick autoinjector that the window turns yellow or if using Erelzi the window turns green, when the injection is complete. If after removing the autoinjector the window has not turned yellow or green, respectively, or it appears drug is still injecting, stress that patient has not received the full dose. If this happens, tell patient to notify prescriber.
- Alert patient using the AutoTouch reusable autoinjector with Enbrel Mini single-dose prefilled cartridge that the AutoTouch makes sounds to help guide the injection. If patient wants to turn the sounds off, she should slide the sound switch up (red bar visible). However, remind patient that

even when the sound is turned off, she will still hear the noise of the motor during the injection and also error alerts. Instruct her what to do if an error alert occurs and how to reset the AutoTouch.

- Instruct patient to rotate injection sites among abdomen, thigh, and upper arms and to avoid areas that are bruised, hard, red, or tender. Advise him to keep each site at least 1 inch away from a previous site.
- Urge patient to use needles and syringes only once and discard in puncture-proof container.
- Stress importance of seeking immediate medical care if a severe allergic reaction occurs. Also, alert patients who are latex-sensitive that the needle cover of the prefilled syringe, the needle cover within the white cap of the SureClick autoinjection, and inside the purple cap of the Enbrel Mini cartridge all contain dry natural rubber, which is a derivative of latex.
- Caution patient that the risk of malignancies such as leukemia and lymphoma may be higher in those who take etanercept, especially children and adolescents. Tell him to seek medical attention promptly for any suspicious signs and symptoms.
- Urge patient to consult prescriber immediately if he develops an infection because drug may decrease the body's infection-fighting ability.
- Caution patient who hasn't had chickenpox to contact prescriber right away if he's exposed because he may develop a more serious infection.
- Urge patient to seek immediate emergency care if he develops a bleeding, bruising, persistent fever or pallor while taking drug.
- Instruct patient to seek medical attention promptly for any unusual or persistent adverse signs or symptoms.
- Advise women of childbearing age to alert prescriber if pregnancy occurs or is suspected. Tell mothers that drug does pass into breast milk, so breastfeeding should be discussed with prescriber before doing so.

## ethacrynic acid

### **Edecrin**

## ethacrynate sodium

# Edecrin

## Class and Category

*Pharmacologic class:* Loop diuretic

*Therapeutic class:* Diuretic

## Indications and Dosages

- *To promote diuresis in heart failure; hepatic cirrhosis; renal disease; ascites of short duration caused by cancer, idiopathic edema, or lymphedema; and edema in hospitalized children other than infants, with congenital heart disease or nephrotic syndrome*

### ORAL SOLUTION, TABLETS

**Adults.** *Initial:* 50 to 100 mg daily as a single dose or in divided doses. Dosage increased by 25 to 50 mg daily, as needed. *Maintenance:* 50 to 200 mg daily.

**Children (except infants).** *Initial:* 25 mg daily. Dosage increased in 25-mg increments daily, as needed.

- *To provide rapid onset of diuresis, when needed, in acute pulmonary edema or when gastrointestinal absorption is impaired or oral medication is not practicable.*

### I.V. INFUSION, I.V. INJECTION

**Adults.** *Initial:* 50 mg or 0.5 to 1 mg/kg. Dose repeated in 2 to 4 hr, if needed. *Maximum:* 100 mg as single dose. I.V. infusion given slowly over at least 30 min and I.V. injection given slowly over several minutes with a running infusion.

Route	Onset	Peak	Duration
P.O.	30 min	2 hr	6–8 hr
I.V.	5 min	15–30 min	2 hr

## Mechanism of Action

Probably inhibits the sulfhydryl-catalyzed enzyme systems that cause sodium and chloride resorption in the proximal and distal tubules and the ascending limb of the loop of Henle. These inhibitory effects increase urinary excretion of sodium, chloride, and water, causing profound diuresis. Drug also increases the ammonium, bicarbonate, calcium, excretion of potassium, hydrogen, magnesium, and phosphate.

## Contraindications

Anuria; hypersensitivity to ethacrynic acid, ethacrynate sodium, or their components; infancy; severe diarrhea

## Interactions

### DRUGS

*aminoglycosides, some cephalosporins*: Increased risk of ototoxicity

*digoxin*: Increased risk of digitalis toxicity

*lithium*: Increased risk of lithium toxicity

*NSAIDs*: Possibly decreased effects of ethacrynic acid

*warfarin*: Increased risk of bleeding

## Adverse Reactions

**CNS:** Confusion, fatigue, headache, malaise, nervousness

**CV:** Orthostatic hypotension

**EENT:** Blurred vision, hearing loss, ototoxicity (ringing or buzzing in ears), sensation of fullness in ears, yellow vision

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Abdominal pain, anorexia, diarrhea, dysphagia, **GI bleeding (I.V.)**, nausea, vomiting

**GU:** Hematuria (I.V. form), interstitial nephritis, polyuria

**HEME:** **Agranulocytosis, severe neutropenia, thrombocytopenia**

**SKIN:** Rash

**Other:** Hyperuricemia, **hypochloremic alkalosis, hypokalemia, hypomagnesemia, hyponatremia**, hypovolemia, infusion-site irritation and pain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

**WARNING** Give ethacrynic acid and ethacrynate sodium cautiously in patients with advanced hepatic cirrhosis, especially those with a history of electrolyte imbalance or hepatic encephalopathy; both forms of drug may lead to lethal hepatic coma.

- Dilute ethacrynate sodium with D<sub>5</sub>W or normal saline solution for I.V. infusion. Discard unused portion after 24 hours.
- Don't use diluted ethacrynate sodium that's cloudy or opalescent.
- Infuse I.V. ethacrynate sodium slowly over 30 minutes if given as an infusion or injected directly into a running infusion slowly over several minutes.
- Weigh patient daily, and assess him for signs and symptoms of dehydration and electrolyte imbalances.
- Monitor blood pressure and fluid intake and output, and check laboratory test results.
- Report significant changes. Prescriber may reduce dosage or temporarily stop drug.
- Know that if hypokalemia develops, administer replacement potassium, as ordered.
- Monitor serum glucose level frequently, especially if patient has diabetes mellitus; both forms of drug may cause hyperglycemia or hypoglycemia.
- Notify prescriber if patient experiences hearing loss; buzzing, sense of fullness, or ringing in his ears; or vertigo. Drug may have to be discontinued.

## **PATIENT TEACHING**

- Instruct patient to take the last dose of ethacrynic acid several hours before bedtime to avoid sleep interruption from diuresis. If patient receives once-daily dosing, advise him to take the dose in the morning to avoid sleep disturbance caused by nocturia.
- Suggest that patient take ethacrynic acid with food or milk to reduce the likelihood of GI distress.
- Advise patient to change position slowly to minimize effects of orthostatic hypotension, especially if he also takes an antihypertensive.

- Urge patient to eat more high-potassium foods unless contraindicated and to take a potassium supplement, if prescribed, to prevent hypokalemia.
- Caution patient not to drink alcohol, stand for prolonged periods, or exercise during hot weather because these activities may exacerbate orthostatic hypotension.
- Instruct patient to notify prescriber if he has buzzing, fullness, or ringing in his ears; diarrhea; hearing loss; severe nausea; vertigo; or vomiting. Drug may need to be discontinued.
- Remind diabetic patients to check their serum glucose levels often for changes.

## ethambutol hydrochloride

**Etibi (CAN), Myambutol**

### Class and Category

*Pharmacologic class:* Synthetic antituberculotic

*Therapeutic class:* Antituberculotic

### Indications and Dosages

- *As adjunct to treat pulmonary tuberculosis caused by Mycobacterium tuberculosis*

#### **TABLETS**

**Adults and adolescents who haven't received previous antituberculotic therapy.** 15 mg/kg daily.

**Adults and adolescents who have received antituberculotic therapy.** 25 mg/kg daily; after 60 days, decreased to 15 mg/kg daily.

# Mechanism of Action

May suppress bacterial multiplication by interfering with RNA synthesis in susceptible bacteria that are actively dividing.

# Contraindications

Hypersensitivity to ethambutol or its components, inability to report changes in vision, optic neuritis

# Interactions

## DRUGS

*antacids that contain aluminum hydroxide:* Decreased absorption of ethambutol

# Adverse Reactions

**CNS:** Burning sensation or weakness in arms and legs, confusion, disorientation, dizziness, fever, headache, malaise, paresthesia, peripheral neuritis

**EENT:** Blurred vision, decreased visual acuity, eye pain, optic neuritis, red-green color blindness

**GI:** Abdominal pain, anorexia, **hepatic dysfunction**, nausea, vomiting

**HEME:** **Leukopenia**, **neutropenia**, **thrombocytopenia**

**MS:** Arthralgia, gouty arthritis, joint pain

**RESP:** **Pulmonary infiltrates**

**SKIN:** Dermatitis, **erythema multiforme**, **exfoliative dermatitis**, pruritus, rash

**Other:** Anaphylaxis, hypersensitivity syndrome, lymphadenopathy

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm. However, there are reports of neonatal ophthalmic abnormalities born to women who took drug during pregnancy.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Expect prescriber to refer patient for an ophthalmologic examination that includes tests for acuity, red-green color blindness, and visual fields before taking ethambutol and monthly thereafter. This is especially likely if therapy is prolonged or dosage exceeds 15 mg/kg daily.

**WARNING** Notify prescriber immediately if patient develops vision changes, and expect ethambutol to be stopped if they occur.

- Expect to give the patient at least one other antituberculous with ethambutol, as prescribed, because bacteria may become resistant quickly to a single drug.
- Monitor laboratory test results for changes in liver function or for increased serum uric acid level if patient has gouty arthritis or impaired renal function. Notify prescriber of any abnormalities.

- Obtain a monthly sputum specimen, as ordered, to check bacteriologic response in sputum-positive patient.
- Know that successful ethambutol therapy typically takes 6 to 12 months but may take years.

## PATIENT TEACHING

- Teach patient to recognize possible adverse reactions to ethambutol.
- Advise patient to take drug with food if he experiences adverse GI reactions.
- Instruct patient to take a missed dose as soon as he remembers, unless it's nearly time for the next dose, but not to double-dose.
- Explain that ethambutol therapy may last months or years and that compliance is essential.
- Advise patient to notify prescriber if no improvement occurs within 3 weeks of starting ethambutol therapy; if bothersome or severe adverse reactions occur; if his vision changes; or if a fever, joint pain, or rash (possible hypersensitivity) develops.

**ethosuximide**

**Zarontin**

## Class and Category

*Pharmacologic class:* Succinimide

*Therapeutic class:* Anticonvulsant

## Indications and Dosages

➤ *To manage absence (petit mal) seizures*

## **CAPSULES, SYRUP**

**Adults and children age 6 and over.** *Initial:* 500 mg daily. *Maintenance:* Increased by 250 mg every 4 to 7 days until control is achieved with minimal adverse reactions.

*Optimal for children:* 20 mg/kg/day.

**Children ages 3 to 6.** *Initial:* 250 mg daily. *Maintenance:* Increased by 250 mg every 4 to 7 days until control is achieved with minimal adverse reactions. *Optimal:* 20 mg/kg/day.

## **Mechanism of Action**

Elevates the seizure threshold and reduces the frequency of attacks by depressing the motor cortex and elevating the threshold of CNS response to convulsive stimuli.

## **Contraindications**

Hypersensitivity to ethosuximide, other succinimides, or their components

## **Interactions**

### **DRUGS**

*phenytoin:* Possibly increased blood phenytoin level

*valproic acid:* Increased or decreased blood ethosuximide level

## **Adverse Reactions**

**CNS:** Aggressiveness, ataxia, decreased concentration, depression, dizziness, drowsiness, euphoria, fatigue, headache, hyperactivity, irritability, lethargy,

lightheadedness, nightmares, psychosis, sleep disturbance, **suicidal ideation**, unsteadiness when walking

**EENT:** Gingival hypertrophy, myopia, tongue swelling

**GI:** Abdominal and epigastric pain, abdominal cramps, anorexia, diarrhea, hiccups, indigestion, nausea, vomiting

**GU:** Increased libido, microscopic hematuria, vaginal bleeding

**HEME:** **Agranulocytosis, aplastic anemia**, eosinophilia, **leukopenia, pancytopenia**

**SKIN:** Erythematous and pruritic rashes, hirsutism, **Stevens-Johnson syndrome**, systemic lupus erythematosus, urticaria

**Other:** **Drug reaction with eosinophilia and systemic symptoms (DRESS), hypersensitivity reaction**, weight loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.
- Drug may cause fetal harm as reports indicate a potential increase risk of birth defects.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Use ethosuximide with extreme caution in patients with hepatic or renal disease.
- Give other anticonvulsants concurrently, as prescribed, to control generalized tonic-clonic seizures.
- Monitor CBC and platelet count and assess for signs of infection, such as cough, fever, and pharyngitis. Also routinely evaluate liver and renal function test results.
- Take safety precautions because drug may cause adverse CNS reactions, such as dizziness and drowsiness.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.
- Assess patient regularly for signs of skin adverse effects. Stop ethosuximide immediately at first sign of rash and notify prescriber.

## PATIENT TEACHING

- Emphasize the importance of complying with ethosuximide regimen.
- Advise patient to take a missed dose as soon as he remembers, unless it's nearly time for the next dose. Warn him not to double the dose.
- Instruct patient not to engage in potentially hazardous activities until drug's CNS effects are known.
- Caution patient not to stop taking drug abruptly; doing so increases the risk of absence seizures.
- Inform patient that the most common side effects of ethosuximide therapy include diarrhea, dizziness or lightheadedness, fatigue, headache, hiccups, indigestion, loss of concentration or appetite, nausea, stomach pain, unsteadiness when walking, vomiting, and weight loss.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report any concerns immediately to prescriber.
- Advise patient or caregiver that prescriber should be notified immediately if a skin rash develops. Also tell patient to notify prescriber if persistent or serious adverse effects develop while taking ethosuximide.

- Caution female patient of childbearing age to use effective contraception methods while taking ethosuximide and to alert prescriber if pregnancy is suspected or known, as drug may cause fetal harm. Encourage female patient who becomes pregnant while taking ethosuximide to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that this registry is collecting information about the safety of antiepileptic drugs during pregnancy.
- Inform female patients desiring to breastfeed an infant that ethosuximide does pass into human breast milk. Advise patient to discuss the benefits against the risks with prescriber before doing so.

## ethotoin

### Peganone

## Class and Category

*Pharmacologic class:* Hydantoin

*Therapeutic class:* Anticonvulsant

## Indications and Dosages

➤ *To manage tonic-clonic and complex partial seizures*

### **TABLETS**

**Adults and adolescents.** *Initial:* 0.5 to 1 g on the first day in 4 to 6 divided doses, increased over several days until desired response is reached. *Maintenance:* 2 to 3 g daily in 4 to 6 divided doses. *Maximum:* 3 g daily.

**Children.** *Initial:* Up to 750 mg daily, based on weight and age, in 4 to 6 divided doses, adjusted as needed and

tolerated. *Maintenance*: 0.5 to 1 g daily in 4 to 6 divided doses. *Maximum*: 3 g daily.

***DOSAGE ADJUSTMENT*** For debilitated patients, initial dosage lowered to reduce the risk of adverse reactions.

## Mechanism of Action

Limits the spread of seizure activity and the start of new seizures by:

- regulating voltage-dependent sodium and calcium channels in neurons
- inhibiting calcium movement across neuronal membranes
- enhancing sodium-potassium adenosine triphosphatase activity in neurons and glial cells.

These actions may result from ethosuximide's ability to slow the recovery rate of inactivated sodium channels.

## Contraindications

Hematologic disorders; hepatic dysfunction; hypersensitivity to ethosuximide, other hydantoins, or their components

## Interactions

### DRUGS

*drugs affecting hematopoietic system*: Increased risk of hematologic adverse effects

*oral anticoagulants*: Possibly decreased serum levels of oral anticoagulants with decreased effectiveness; increased serum ethosuximide levels with possible toxicity

# Adverse Reactions

**CNS:** Clumsiness, confusion, drowsiness, excitement, peripheral neuropathy, sedation, slurred speech, stuttering, **suicidal ideation**, tremor

**EENT:** Nystagmus

**GI:** Constipation, diarrhea, nausea, vomiting

**HEME:** **Agranulocytosis, leukopenia, thrombocytopenia**

**SKIN:** Rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**

**Other:** Lymphadenopathy, systemic lupus erythematosus

# Childbearing Considerations

## PREGNANCY

- Drug can cause fetal harm resulting in an increased risk of birth defects.
- Use with caution only if benefit to mother to control seizure activity outweighs potential risk to fetus.
- Drug given during pregnancy may cause a neonatal coagulation defect causing bleeding usually within 24 hours after birth. Vitamin K administered to mother one month prior to and during delivery, and to the infant, intravenously, immediately after birth may prevent bleeding.

## LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

# Nursing Considerations

- Obtain CBC and differential before treatment and monthly for first few months of ethosuximide therapy, as ordered.

**WARNING** Know that ethosuximide shouldn't be stopped abruptly because of risk of status epilepticus. Plan to reduce dosage gradually or substitute another drug, as prescribed.

- Monitor patient for signs and symptoms of infection or unusual bleeding because ethosuximide may cause hematologic toxicity.
- Know that because of ethosuximide's potential for hepatotoxicity, monitor liver enzymes and expect drug to be discontinued if test results are abnormal.
- Notify prescriber immediately and expect ethosuximide to be stopped and replaced with another drug if patient has decreased blood counts, enlarged lymph nodes, or rash.
- Be aware that ethosuximide may be substituted for phenytoin without loss of seizure control if patient develops severe gingival hyperplasia or other adverse reactions. Expect ethosuximide dosage to be 4 to 6 times greater than phenytoin dosage.
- Institute and maintain seizure precautions according to facility protocol.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

## PATIENT TEACHING

- Instruct patient to take ethosuximide exactly as prescribed and not to stop it abruptly.
- Advise patient to take drug with food to enhance absorption and reduce adverse GI effects.
- Advise patient to report easy bruising, epistaxis, fever, malaise, petechiae, or sore throat to prescriber immediately.
- Instruct patient to keep medical appointments to monitor drug effectiveness and check for adverse reactions. Explain the need for periodic laboratory tests.
- Urge patient to avoid alcohol during ethosuximide therapy.

- Caution patient to avoid hazardous activities until drug's adverse effects are known.
- Encourage patient to wear or carry medical identification indicating his diagnosis and drug therapy.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report any concerns immediately to prescriber.
- Advise patient to tell all healthcare providers about ethotoin therapy because drug may react with other medication, including herbal supplements, over-the-counter drugs, and vitamins.

## etidronate disodium

### Class and Category

*Pharmacologic class:* Bisphosphonate

*Therapeutic class:* Antihypercalcemic agent, bone resorption inhibitor

### Indications and Dosages

- *To treat Paget's disease of bone (osteitis deformans)*

#### **TABLETS**

**Adults.** 5 to 10 mg/kg daily for up to 6 months, or 11 to 20 mg/kg daily for up to 3 months.

*Maximum:* 20 mg/kg daily.

*Retreatment:* As needed, only after at least 90 days from last dose and evidence of active disease process is present.

- *To prevent and treat heterotopic ossification after total hip replacement*

## **TABLETS**

**Adults.** 20 mg/kg daily for 1 month before surgery and then 20 mg/kg daily for 3 months after surgery for a total of 4 months of treatment.

- *To prevent and treat heterotopic ossification after spinal cord injury*

## **TABLETS**

**Adults.** 20 mg/kg daily for 2 wk and then 10 mg/kg daily for 10 wk for a total of 12 wk of treatment.

## **Mechanism of Action**

Inhibits normal and abnormal bone resorption by reducing bone turnover and slowing the remodeling of pagetic or heterotopic bone. Etidronate also decreases the elevated cardiac output seen in Paget's disease of bone and reduces local increases in skin temperature. It also inhibits the abnormal bone resorption that may occur with cancer and reduces the amount of calcium that enters the blood from resorbed bone.

## **Contraindications**

Clinically overt osteomalacia, esophageal abnormalities that delay gastric emptying, such as achalasia and stricture; hypersensitivity to etidronate, bisphosphonates, or their components

## **Interactions**

## **DRUGS**

*antacids that contain aluminum, calcium, or magnesium; vitamin and mineral supplements that contain aluminum, calcium, iron, or magnesium:* Decreased etidronate absorption

*warfarin:* Possibly increased prothrombin time

## **FOODS**

*high-calcium food (such as milk and other dairy products):* Decreased etidronate absorption

## **Adverse Reactions**

**CNS:** Amnesia, confusion, depression, hallucination, headache, paresthesias

**EENT:** Altered taste, glossitis, metallic taste

**GI:** Diarrhea, elevated liver enzymes, nausea

**GU:** **Nephrotoxicity**

**HEME:** **Agranulocytosis, leukopenia, pancytopenia**

**MS:** Atypical arthralgia, arthritis, atypical subtrochanteric and diaphyseal femoral fractures, bone pain, leg cramps, osteomalacia, osteonecrosis of jaw

**SKIN:** Alopecia, follicular eruption, macular rash, maculopapular rash, pruritus, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria

**Other:** **Angioedema, hypocalcemia**

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm.

- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Infants should be monitored for adverse reactions, especially skeletal, if woman becomes pregnant during or after completing a course of bisphosphonate therapy.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use etidronate cautiously in patients with upper GI problems such as Barrett's esophagus, duodenitis, dysphagia, gastritis, other esophageal diseases, or ulcers because drug may cause local irritation of the upper GI mucosa.
- Anticipate starting etidronate as soon as possible after spinal cord injury, preferably before signs of heterotopic ossification.
- Expect etidronate not to inhibit healing of spinal fractures, affect prosthesis, or disrupt trochanter attachment when used after total hip replacement.
- Give 2 hours before meals to prevent decreased absorption.

**WARNING** Watch for hypocalcemia if patient receives parenteral form for more than 3 days.

- Know that when treating hypercalcemia, you should expect to continue giving drug for up to 90 days if serum calcium level remains within acceptable range.
- Monitor patient for adverse esophageal effects such as esophagitis, esophageal erosions, and esophageal ulcers that may occur with bleeding, as well as duodenal and gastric ulcers, because these adverse effects have occurred with other oral bisphosphonates.
- Know that risk of severe adverse esophageal reactions increases in patients who lie down after taking drug, who fail to swallow it with a full

glass of water, or who continue to take drug after developing symptoms of esophageal irritation.

- Make sure patient has had a dental checkup before having an invasive dental procedures during etidronate therapy, especially if he has cancer; is receiving chemotherapy, head or neck radiation, or a corticosteroid; or has poor oral hygiene because the risk of osteonecrosis of the jaw is increased in these patients. Be aware that the risk increases the longer the patient takes etidronate.

## **PATIENT TEACHING**

- Instruct patient to take etidronate tablets on an empty stomach—2 hours before meals, antacids, or calcium supplements. Urge him to drink a full glass of water with tablets and to avoid taking drug with milk or other high-calcium foods.
- Tell patient to take a missed dose as soon as he remembers as long as 2 hours have elapsed since his last meal. Instruct him not to eat for another 2 hours. Warn against doubling the dose.
- Inform patient with Paget's disease that his response to etidronate may be slow and may continue for months after treatment.
- Instruct patient to inform prescriber if he develops chest pain, difficulty swallowing or pain when swallowing, or new or worsening heartburn.
- Advise patient to notify prescriber if he develops new or worsening groin or thigh pain.
- Stress importance of patient notifying prescriber if invasive dental procedures are going to be done because etidronate therapy may need to be discontinued as the risk of osteonecrosis of the jaw may be decreased in the absence of etidronate therapy.

**etravirine**

**Intelence**

## **Class and Category**

*Pharmacologic class:* Non-nucleoside reverse transcriptase inhibitor (NNRTI)

*Therapeutic class:* Antiretroviral

## Indications and Dosages

- *As adjunct to treat HIV-1 infection in patients who are antiretroviral treatment-experienced*

### **TABLETS**

**Adults, pregnant women, and children ages 2 to 18 weighing 30 kg (66 lb) or more.** 200 mg twice daily following a meal.

**Children ages 2 to 18 yr weighing 25 kg (55 lb) to less than 30 kg (66 lb).** 150 mg twice daily following a meal.

**Children ages 2 to 18 yr weighing 20 kg (44 lb) to less than 25 kg (55 lb).** 125 mg twice daily following a meal.

**Children ages 2 to 18 yr weighing 16 kg (35.2 lb) to less than 20 kg (44 lb).** 100 mg twice daily following a meal.

## Mechanism of Action

Binds directly to reverse transcriptase and blocks the RNA-dependent and DNA-dependent DNA polymerase activities by causing a disruption of the enzyme's catalytic site.

## Contraindications

Hypersensitivity to etravirine or its components

## Interactions

## DRUGS

*amiodarone, artemether, atazanavir, atazanavir/ritonavir, atorvastatin, bepridil, buprenorphine, clopidogrel, cyclosporine, dihydroartemisinin, disopyramide, dolutegravir, dolutegravir/darunavir/ritonavir, dolutegravir/lopinavir/ritonavir, flecainide, indinavir, lidocaine (systemic), lovastatin, lumefantrine, maraviroc, mexiletine, propafenone, quinidine, rilpivudine, sildenafil, simvastatin, sirolimus, tacrolimus, telaprevir, warfarin:* Decreased plasma concentrations of these drugs with possible decreased effectiveness

*boceprevir:* Decreased plasma concentration of etravirine with possible decreased effectiveness; increased plasma concentration of boceprevir with possible increased risk of adverse reactions

*carbamazepine, darunavir/ritonavir, dexamethasone (systemic), efavirenz, lopinavir/ritonavir, nevirapine, phenobarbital, phenytoin, rifampin, rifapentine, ritonavir, St. John's wort, saquinavir/ritonavir, tipranavir/ritonavir:* Decreased plasma concentration of etravirine and its effectiveness

*clarithromycin, itraconazole, ketoconazole:* Decreased plasma concentrations of these drugs with possible decreased effectiveness; increased plasma concentration of etravirine

*delavirdine:* Increased plasma concentration of etravirine with possible increased risk of serious adverse reactions

*diazepam, digoxin, fluvastatin, fosamprenavir, fosamprenavir/ritonavir, maraviroc/darunavir/ritonavir, nelfinavir, pitavastatin:* Increased plasma concentration of these drugs with possible increased risk of serious adverse reactions

*rifabutin*: Decreased plasma concentration of both etravirine and rifabutin with possible decreased effectiveness of both drugs

*voriconazole*: Increased plasma concentrations of both etravirine and voriconazole with possible increased risk of serious adverse reactions

## Adverse Reactions

**CNS:** Abnormal dreams, amnesia, anxiety, confusion, **CVA**, difficulty concentrating, disorientation, fatigue, fever, general malaise, hypoesthesia, nervousness, nightmares, paresthesia, peripheral neuropathy, **seizures**, sleep disorders, sluggishness, somnolence, syncope, tremor, vertigo

**CV:** Angina pectoris, **atrial fibrillation**, dyslipidemia, elevated cholesterol and triglyceride levels, **MI**

**EENT:** Blurred vision, conjunctivitis, dry mouth, oral lesions, stomatitis

**ENDO:** Cushingoid appearance, diabetes mellitus, fat redistribution, gynecomastia, hyperglycemia

**GI:** Abdominal distention, anorexia, constipation, elevated liver or pancreatic enzymes, flatulence, gastroesophageal reflux disease, gastritis, hematemesis, **hepatic failure**, hepatic steatosis, **hepatitis**, hepatomegaly, **pancreatitis**, vomiting

**GU:** **Acute renal failure**, elevated creatinine level

**HEME:** Decreased hemoglobin eosinophilia, **hemolytic anemia**, **leukopenia**, **neutropenia**, **thrombocytopenia**

**MS:** Joint or muscle aches, **rhabdomyolysis**

**RESP:** **Bronchospasm**, exertional dyspnea

**SKIN:** Blisters, diaphoresis, dry skin, **erythema multiforme**, lipohypertrophy, night sweats, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other:** **Angioedema**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, immune reconstitution syndrome, lipodystrophy

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## Nursing Considerations

- Administer etravirine twice daily following meals.
- Dissolve tablet in 5 ml of water and stir well until the water looks milky for the patient who cannot swallow tablets. If needed, mixture can be further diluted with milk or orange juice (not carbonated beverages, grapefruit juice, or warm liquids). However, water must be used first to dissolve tablet before any other liquid is used. Have patient drink mixture immediately and then add more milk, orange juice, or water to glass and have patient drink it. Do this several times to ensure that patient has received the entire dose.

**WARNING** Assess patient for skin alterations, especially a rash that may occur anytime but most commonly within the first 6 weeks of treatment because, although uncommon, etravirine has caused severe skin and hypersensitivity reactions. Notify prescriber immediately if rash and other symptoms that may accompany the rash (such as angioedema, blisters, fatigue, jaundice, joint or muscle aches, or oral lesions) occur. Expect to check patient's liver enzymes and drug to be discontinued if rash is serious. Know that symptoms can evolve into a life-threatening reaction if drug is not promptly discontinued.

- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including etravirine. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.
- Observe patient for redistribution of body fat, including breast enlargement, central obesity, development of buffalo hump, facial wasting, and peripheral wasting, which may produce a cushingoid-type appearance.

## **PATIENT TEACHING**

- Tell patient to take etravirine twice daily following a meal. Tell her not to chew the tablets but to swallow them whole.
- Instruct patient to swallow the tablet(s) with a liquid such as water. If patient is unable to swallow tablet, tell her to do the following: place tablet in a glass containing 1 teaspoon of water; stir well until water is milky looking; add more water or alternatively milk or orange juice, if needed (milk or orange juice should only be used after water has been used first); drink immediately; add milk, orange juice, or water to glass and drink. Repeat this procedure several times to ensure that entire dose has been taken. Caution patient not to use carbonated beverages, grapefruit juice, or warm liquids to dissolve drug.

- Advise patient that if a dose is missed and it is less than 6 hours from the time it is usually taken, she should take the drug following the intake of a meal. However, if it is longer than 6 hours, tell her to skip the dose and resume her normal dosing schedule with the next dose.
- Tell mothers not to breastfeed their infants while receiving etravirine.
- Alert patient to the possibility of fat distribution with the appearance of a buffalo hump, thin extremities and face, and breast enlargement.
- Instruct patient to inform all prescribers of etravirine therapy and not to take any drugs, including over-the-counter drugs and herbal medicines, without prescriber consent, because etravirine interacts with many drugs.

**WARNING** Tell patient to notify prescriber immediately of any alteration in skin but especially a rash that may be associated with other symptoms. Drug will have to be discontinued if serious.

## everolimus

**Afinitor, Afinitor Disperz, Zortress**

### Class and Category

*Pharmacologic class:* mTOR kinase inhibitor

*Therapeutic class:* Immunosuppressant

### Indications and Dosages

- *As adjunct to prevent organ rejection in renal transplantation*

### **TABLETS (ZORTRESS)**

**Adults.** *Initial:* 0.75 mg twice daily in combination with reduced-dose cyclosporine, administered as soon as possible after transplantation.

- *As adjunct to prevent organ rejection in liver transplantation*

## **TABLETS (ZORTRESS)**

**Adults.** *Initial:* 1 mg twice daily in combination with reduced-dose tacrolimus begun 30 days post-transplant.

**DOSAGE ADJUSTMENT** For patient taking Zortress, dosage adjusted at 4- to 5-day intervals, as needed, according to everolimus blood concentrations, tolerability, change in concomitant medications, the clinical situation, and individual response. For patients with mild hepatic impairment, initial daily dose reduced by one-third, and for patients with moderate or severe hepatic impairment, initial daily dose is reduced by 50% with further adjustments made according to everolimus blood concentration levels.

- *To treat advanced hormone receptor-positive, HER2-negative breast cancer in postmenopausal women in combination with exemestane after failure of treatment with anastrozole or letrozole; to treat progressive neuroendocrine tumors of pancreatic origin or are progressive, well-differentiated, nonfunctional tumors of gastrointestinal or lung origin that are locally advanced, metastatic, or unresectable; to treat renal cell carcinoma after failure of treatment with sorafenib or sunitinib; to treat tuberous sclerosis complex-associated renal angiomyolipoma that does not require immediate surgery*

## **TABLETS (AFINITOR)**

**Adults.** 10 mg once daily. Treatment continued until disease progression or unacceptable toxicity occurs.

- *To treat tuberous sclerosis complex-associated subependymal giant cell astrocytoma (SEGA)*

## **ORAL SUSPENSION (AFINITOR DISPERZ), TABLETS (AFINITOR)**

**Adults and children age 1 year and over.** 4.5 mg/m<sup>2</sup> once daily until disease progresses or unacceptable toxicity occurs.

- *As adjunct to treat tuberous sclerosis complex-associated partial-onset seizures*

## **ORAL SUSPENSION (AFINITOR DISPERZ)**

**Adults and children age 2 years and over.** 5 mg/m<sup>2</sup> once daily until disease progresses or unacceptable toxicity occurs.

***DOSAGE ADJUSTMENT*** For patients taking Afinitor or Afinitor Disperz, dosage adjusted according to degree of adverse reactions present. Also, for patients with breast cancer, neuroendocrine tumors, renal cell carcinoma, or tuberous sclerosis complex-associated renal angiomyolipoma and mild hepatic impairment, dosage reduced to 7.5 mg once daily or 5 mg once daily if higher dose is not tolerated; for moderate hepatic impairment, dosage reduced to 5 mg once daily or 2.5 mg once daily if higher dose is not tolerated; and for patients with severe hepatic impairment, dosage reduced to 2.5 mg once daily. For patients with tuberous sclerosis complex-associated subependymal giant cell astrocytoma or tuberous sclerosis complex-associated partial-onset seizures and severe hepatic impairment, dosage reduced to 2.5 mg/m<sup>2</sup> once daily. For patient taking a P-gp and moderate CYP3A inhibitors and who has breast

cancer, neuroendocrine tumor, renal cell carcinoma, or tuberous sclerosis complex-associated renal angiomyolipoma, dosage reduced to 2.5 mg once daily, with dosage then increased to 5 mg once daily, if tolerated. For patients taking P-gp and moderate CYP3A inhibitors and who have tuberous sclerosis complex-associated subependymal giant cell astrocytoma or tuberous sclerosis complex-associated partial-onset seizures, daily dosage reduced by 50%. For patients taking a P-gp and strong CYP3A4 inducers and who have any indication treated by everolimus, dosage doubled using increments of 5 mg or less.

## **Mechanism of Action**

Causes immunosuppression by inhibiting antigenic and interleukin (IL-2 and IL-15) stimulated activation and proliferation of B and T lymphocytes.

## **Contraindications**

Hypersensitivity to everolimus, other rapamycin derivatives, or their components

## **Interactions**

### **DRUGS**

*ACE inhibitors:* Possibly increased risk of angioedema  
*amprenavir, aprepitant, atazanavir, clarithromycin, cyclosporine, digoxin, diltiazem, erythromycin, fluconazole, fosamprenavir, indinavir, itraconazole, ketoconazole, macrolide antibiotics, nefazodone, nelfinavir, nicardipine, ritonavir, saquinavir, telithromycin, verapamil, voriconazole:*  
Possible increased blood everolimus level

*anticonvulsants, carbamazepine, efavirenz, nevirapine, phenobarbital, phenytoin, rifabutin, rifampin, rifapentine, St. John's wort*: Possibly decreased blood everolimus level  
*lovastatin, simvastatin*: Possible development of rhabdomyolysis and other adverse reactions  
*octreotide (depot)*: Increased octreotide levels  
*live vaccines*: Possibly increased risk of contracting disease from live virus; decreased therapeutic effect of vaccine

## **FOODS**

*grapefruit, grapefruit juice*: Possibly decreased metabolism of everolimus increasing everolimus level

## **Adverse Reactions**

**CNS**: Aggression, agitation, anxiety, asthenia, chills, dizziness, fatigue, fever, headache, insomnia, **progressive multiple leukoencephalopathy (PML)**, multiple, paresthesia, reflex sympathetic dystrophy

**CV**: **Arterial thrombotic events**, chest pain, **congestive heart failure, deep vein thrombosis**, hyperlipidemia, hypertension, **pericardial effusion**, peripheral edema, tachycardia

**EENT**: Conjunctivitis, dry mouth, epistaxis, eyelid pain, oropharyngeal pain, rhinorrhea, stomatitis

**ENDO**: Hot flashes, hyperglycemia, new-onset diabetes mellitus

**GI**: Abdominal pain, anorexia, ascites, cholecystitis, cholelithiasis, constipation, diarrhea, elevated bilirubin or liver enzymes, gastroenteritis, **hepatic artery thrombosis** (liver transplant), nausea, **pancreatitis**

**GU:** Acute renal failure, amenorrhea, azospermia, BK virus-associated nephropathy, elevated creatinine level, kidney graft thrombosis, nephrotoxicity, oligospermia, proteinuria, UTI

**HEME:** Anemia, bleeding, elevated partial thromboplastin time, elevated prothrombin time, leukopenia, lymphopenia, neutropenia, thrombocytopenia

**MS:** Arthralgia; back, extremity, or jaw pain; muscle spasm; myalgia

**RESP:** Cough, dyspnea, interstitial lung disease, noninfectious pneumonitis, pleural effusion, pulmonary embolism, upper respiratory infection

**SKIN:** Acne, alopecia, dermatitis, erythema, nail disorders, pruritus, rash, skin cancer

**Other:** Angioedema; decreased bicarbonate level; delayed wound healing; elevated alkaline phosphatase; hyperkalemia; hypersensitivity reactions; hypocalcemia; hypokalemia; hyponatremia; hypophosphatemia; infections such as bacterial, fungal, protozoal, and viral; lymphomas and other malignancies; opportunistic infections including polyoma virus; sepsis; septic shock; weight loss

## Childbearing Considerations

### PREGNANCY

- A negative pregnancy test result required before starting drug therapy.
- Drug may cause fetal harm based on animal studies.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Breastfeeding should not occur during drug therapy.

## **REPRODUCTION**

- Advise women of childbearing potential to use highly effective contraception methods while receiving drug and up to 8 weeks after drug is discontinued.
- Advise male patients with female partners of childbearing potential to use effective contraception during treatment and for 4 weeks after the last dose.
- Drug therapy may cause both female and male infertility.

## **Nursing Considerations**

- Be aware that Zortress brand of everolimus isn't recommended in transplants other than kidney or liver transplantation. Know that everolimus therapy should not begin until 30 days after liver transplant because of patient's increased risk of developing hepatic artery thrombosis, which may lead to graft loss or death.
- Be aware that another form of everolimus under the trade names of Afinitor and Afinitor Disperz are used only to treat certain cancers. The three brands are not interchangeable. To avoid a medication error, make sure that the Zortress brand is being administered for prevention of kidney or liver transplant rejection and do not interchange Afinitor with Afinitor Disperz.
- Know that patients with galactose intolerance, glucose-galactose malabsorption, or Lapp lactase deficiency should not receive everolimus therapy because this may result in diarrhea and malabsorption.
- Expect female patient of childbearing age to undergo a pregnancy test prior to initiating everolimus therapy, because drug can cause fetal harm.
- Assess patient's renal function before therapy with Afinitor or Afinitor Disperz brand of everolimus is begun, and annually thereafter unless patient has underlying risk factors for renal failure. Renal evaluation in these patients should be done every 6 months.

**WARNING** Monitor patient closely for hypersensitivity reactions that could be severe. These may include anaphylaxis, angioedema, chest pain, dyspnea, or flushing. At the first sign of a reaction, notify prescriber, expect to administer emergency treatment according to institutional protocol, and expect drug to be discontinued.

- Measure whole blood trough concentrations of both cyclosporine and everolimus in patient with kidney transplant or tacrolimus and everolimus in liver transplant because of increased risk of nephrotoxicity when either combination of drugs are used or when drug is used to treat malignancies or tuberous sclerosis complex-associated partial-onset seizures. Everolimus levels, ideally drawn 4 to 5 days after a previous dosing change, will also reveal if the therapeutic range has been achieved (3 to 8 ng/ml).
- Know that dosage adjustments of everolimus can then be made, as needed. In addition, everolimus levels should be obtained during concomitant administration of CYP3A4 inducers or inhibitors, when switching cyclosporine formulations, and/or when cyclosporine dosing is reduced as well as in patients with hepatic impairment. Know that there is little to no pharmacokinetic interaction of tacrolimus on everolimus. Therefore, there is no need to alter everolimus dosing if tacrolimus dosing is altered.
- Monitor patient's incision as everolimus delays wound healing and increases the occurrence of wound-related complications such as wound dehiscence, wound infection, incisional hernia, lymphocele, and seroma.

**WARNING** Watch for evidence of infection (such as cough, fever, pain, malaise) because patients receiving immunosuppressants such as everolimus are at increased risk for bacterial, fungal, parasitic, or viral infection. Watch for both generalized and localized infections, including worsening of preexisting infections, and be aware that these infections may become life threatening. Activation of latent viral infections may also occur and include BK-virus-associated nephropathy that can lead to decreased renal function and renal graft loss.

- Be aware that interstitial lung disease may occur in patients with symptoms consistent with infectious pneumonia but usually only becomes apparent when patient does not respond to antibiotic therapy and other causes have been ruled out. If this occurs, expect everolimus therapy to be interrupted until the noninfectious pneumonitis has been resolved. Know that glucocorticoid therapy may also be prescribed to help resolve it.
- Monitor patient, especially within the first 30 days post transplantation, for evidence of kidney arterial and venous thrombosis (kidney transplant) or hepatic artery thrombosis (liver transplant) resulting in graft loss.
- Monitor patient's lipid levels routinely because hyperlipidemia may occur as a result of everolimus therapy. If hyperlipidemia drug therapy is required, be aware that lovastatin or simvastatin should not be used to treat it for patient with a kidney transplant because of a potential interaction with cyclosporine.
- Monitor patient's CBC and platelet count, as ordered, routinely because of increased risk of hemolytic uremic syndrome, thrombotic microangiopathy, or thrombotic thrombocytopenic purpura that may occur with combined everolimus and cyclosporine therapy used with kidney transplantation. Also know that drug causes myelosuppression, which may lead to hematologic disorders such as anemia, lymphopenia, neutropenia, and thrombocytopenia.
- Report abnormalities promptly to prescriber.
- Monitor patient's blood glucose levels regularly because everolimus therapy may increase the risk of new-onset diabetes mellitus after transplant.

## **PATIENT TEACHING**

- Instruct patient to swallow tablets whole with a glass of water and not crushed before ingesting.
- Tell patient that ideally twice daily dosages should be consistently taken approximately 12 hours apart and at the same time as his cyclosporine or tacrolimus dose, if prescribed.
- Instruct patient to report any, persistent, severe, or unusual symptoms to prescriber.
- Caution patient to avoid excessive exposure to ultraviolet light, to wear protective clothing when outdoors, and use a sunscreen with a high protection factor.

- Inform patient that stomatitis most often occurs within the first 8 weeks of treatment. Instruct patient that he will be prescribed a dexamethasone alcohol-free oral solution and to use it as a swish-and-spit mouthwash. Caution him to avoid alcohol-, hydrogen peroxide-, iodine-, or thyme-containing products.
- Advise patient to avoid immunizations that use live vaccines such as BCG, intranasal influenza, measles, mumps, rubella, oral polio, TY21a typhoid, varicella, and yellow fever.
- Emphasize importance of avoiding grapefruit and grapefruit juice while receiving concomitant therapy with everolimus and cyclosporine.
- Urge women of childbearing age to use a highly effective birth control method throughout everolimus therapy and for 8 weeks after the drug has been discontinued.
- Alert both men and women that drug may affect fertility.
- Inform mothers that they should not breastfeed while taking everolimus.

## exenatide

**Bydureon, Bydureon Bcise, Byetta**

### Class and Category

*Pharmacologic class:* Glucagon-like peptide-1 (GLP-1) receptor agonist

*Therapeutic class:* Antidiabetic

### Indications and Dosages

- *Adjunct treatment to diet and exercise to improve blood glucose levels in patients with type 2 diabetes mellitus*

## SUBCUTANEOUS INJECTION (BYETTA)

**Adults.** *Initial:* 5 mcg twice daily, given within 60 min before morning and evening meals. After 1 month, increased, as needed, to 10 mcg twice daily, given within 60 min before morning and evening meals.

## SUBCUTANEOUS INJECTION (BYDUREON, BYDUREON BCISE)

**Adults.** 2 mg once every 7 days.

Route	Onset	Peak	Duration
SubQ	Immediate	2.1 hr	Unknown

## Contraindications

Hypersensitivity to exenatide or its components, personal or family history of medullary thyroid carcinoma or multiple endocrine neoplasia syndrome type 2 (Bydureon)

## Interactions

### DRUGS

*oral antidiabetics such as meglitinides or sulfonylureas, insulin:* Increased risk of hypoglycemia

*oral drugs:* May decrease rate and extent of absorption of these drugs

*warfarin:* Possibly increased INR with increased risk of bleeding

## Adverse Reactions

**CNS:** Asthenia, dizziness, headache, jitteriness, somnolence

**CV:** Chest pain

**EENT:** Decreased taste

**ENDO:** **Hypoglycemia**

**GI:** Abdominal distention or pain, anorexia, cholecystitis, cholelithiasis, constipation, diarrhea, dyspepsia, flatulence, gastroesophageal reflux, indigestion, nausea, **pancreatitis (including life-threatening hemorrhagic or necrotizing)**, vomiting

**GU:** **Acute renal failure**, decreased renal function, elevated serum creatinine level, **kidney transplant dysfunction, worsening chronic renal failure**

**RESP:** **Chronic hypersensitivity pneumonitis**

**SKIN:** Alopecia, diaphoresis, macular or papular rash, pruritus, rash, urticaria

**Other:** **Anaphylaxis, angioedema**, dehydration, elevated antiexenatide antibody level, hematoma, injection-site reactions (abscess, cellulitis, necrosis, pruritus, redness, subcutaneous nodules), weight loss

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm. However, animal studies suggest drug may increase risk for fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **Mechanism of Action**

Normally, when serum glucose level rises, insulin is secreted within 10 minutes. This first-phase insulin response is absent in patients with type 2 diabetes. Exenatide, an incretin mimetic, restores the first-phase insulin response and improves the second-phase response that immediately follows. It does so by promoting incretins that spur insulin synthesis and release from beta cells by binding and activating human GLP-1 receptors to reduce fasting and postprandial serum glucose levels.

The drug also suppresses inappropriately elevated glucagon secretion. Lower serum glucagon level leads to decreased hepatic glucose output and decreased insulin demand. It also slows gastric emptying and thus the rise of serum glucose level.

Description

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that exenatide isn't recommended for patients with severe GI disease, patients with creatinine clearance less than 30 ml/min, or patients having dialysis because of adverse GI or renal effects.

- Use exenatide cautiously in a renal transplant patient or patient with moderate renal disease when dosage of Byetta is increased from 5 to 10 mcg or the extended-release formulations (Bydureon or Bydureon Bcise) are used. Monitor renal function throughout therapy, especially in the elderly, and notify prescriber of abnormalities because drug can cause acute kidney injury, especially if patient becomes hypovolemic from drug-induced nausea and vomiting. Know that drug is not recommended for use in patients with an estimated glomerular filtration rate below 45 ml/min.
- Be aware that exenatide may induce acute gallbladder disease. If cholelithiasis is suspected, expect gallbladder studies to be ordered and appropriate follow up to occur.
- Be aware that if patient also takes a sulfonylurea, the sulfonylurea dosage may need to be decreased to reduce the risk of hypoglycemia. Usually, no dosage adjustment is needed for a patient taking metformin.
- Administer drug into patient's abdomen, thigh, or upper arm.
- Monitor patient's blood glucose level. If control decreases despite the patient's best efforts, drug may have to be discontinued because of the possibility that anti-exenatide antibodies have formed. Be aware that if patient is already taking the rapid-release form of exenatide (Byetta) and is switching to the extended-release form of exenatide (Bydureon or Bydureon Bcise), Byetta must be discontinued first. Also know that he may experience a transient elevation in his blood glucose levels for about 2 weeks as his body adjusts to the extended-release form.
- Monitor patient for evidence of acute pancreatitis, such as persistent, severe abdominal pain accompanied by vomiting, especially when drug is started or dosage increased. Notify prescriber, and expect to stop exenatide and give supportive care.
- Know that the rapid-release form of exenatide (Byetta) may be used concomitantly with insulin glargine (Lantus), which is a long-acting insulin to help improve the patient's blood glucose control. Byetta should not be used with any other type of insulin. If the patient is susceptible to hypoglycemia, expect the insulin glargine dosage to be decreased when used with Byetta.
- Be aware that Bydureon extended-release for injectable suspension can be used as an add-on to basal insulin in adults with type 2 diabetes who have inadequate glycemic control.

## **PATIENT TEACHING**

- Teach patient how to give a subcutaneous injection and how to use pen injector if prescribed Byetta.

- Teach patient how to mix powder with diluent if prescribed Bydureon and how to give a subcutaneous injection. Remind patient to administer Bydureon immediately after the powder is suspended in the diluent and transferred to the syringe. Also tell him not to substitute needles or any other components in the tray. Alert him that a spare needle has been provided in the tray in the event he needs it.
- Inform patient prescribed Bydureon Bcise of the need to shake hard the autoinjector in an up-and-down motion, until the drug is evenly mixed and no whiteness of the drug is seen along the bottom, sides, or top of device. Tell patient he will need to shake the autoinjector for at least 15 seconds. Remind patient that to get the full dose, the drug must be mixed well. When mixed well, the knob on the device should be turned from lock to unlock position. Patient should hear a click.
- Inform patient that exenatide may be administered in the abdomen, thigh, or upper arm. Stress the need to rotate injection sites.
- Tell patient to inspect injection site daily and to report any adverse effects at site that are persistent or appear serious.
- Emphasize the need to use rapid release form of drug (Byetta) within 60 minutes before morning and evening meals or the two main meals of the day, about 6 hours or more apart, never after a meal.
- Know that if patient misses a dose of Byetta, tell him to resume treatment with the next scheduled dose. If patient is prescribed Bydureon and misses a dose, tell him to administer the drug as soon as he remembers as long as his regularly scheduled dose is at least 3 days later. If the time frame is less than this, tell patient to wait until his next regularly scheduled dose. Make patient aware that he may change the day of weekly administration of Bydureon as long as the last dose was administered 3 or more days before.
- Advise patient that drug should look clear and colorless. Tell him not to use drug solution that looks cloudy or colored or contains particles.
- Instruct patient to check expiration date on the vial and not to use drug if date has passed.
- Advise patient to refrigerate rapid-acting drug (Byetta) before first use and protect it from light. After first use of pen device, drug may be stored at room temperature of 25°C (77° F) or less. Advise patient to refrigerate extended-release drug (Bydureon) in refrigerator and protect from light. A single-use tray of Bydureon may be stored at room temperature for up to 4 weeks.
- Tell patient to discard pen injector 30 days after initial use, even if some drug is left. Caution patient not to share his pen or needles with anyone

else.

- Alert patient that pen doesn't come with needles and that he'll need to buy them.
- Warn patient that nausea may occur at the beginning of therapy but usually subsides over time.
- Inform patient taking a sulfonylurea or insulin glargine to be alert for hypoglycemic reactions because risk increases with both drugs. Review ways to treat such reactions, and tell patient to alert prescriber if they occur often or are severe.
- Instruct female patient of childbearing potential to tell her prescriber if she is, could be, or is planning to become pregnant.
- Tell patient to seek emergency care for persistent, severe abdominal pain and vomiting.
- Caution patient that exenatide doesn't replace diet and exercise measures.

**WARNING** Urge patient to stop taking drug and seek immediate emergency care if signs and symptoms of an allergic reaction occur.

- Alert patient taking extended-release form to report difficulty breathing or swallowing, hoarseness, or a lump in neck.
- Tell patient that kidney function may become impaired, especially if dehydration occurs, and to let prescriber know if patient becomes dehydrated.

**ezetimibe**

**Zetia**

## **Class and Category**

*Pharmacologic class:* Cholesterol absorption inhibitor

*Therapeutic class: Antilipemic*

## Indications and Dosages

- *To treat heterozygous familial and nonfamilial hypercholesterolemia or homozygous sitosterolemia; as adjunct with HMG-CoA reductase inhibitors to treat heterozygous familial and nonfamilial hypercholesterolemia; with fenofibrate to treat mixed hyperlipidemia and with atorvastatin or simvastatin to treat patients with homozygous familial hypercholesterolemia*

## Mechanism of Action

Reduces blood cholesterol by inhibiting its absorption through the small intestine.

Normally, in the intestinal lumen, lipids break down to cholesterol and other substances that create smaller droplets called micelles, as shown below left. The micelles enter intestinal epithelial cells called enterocytes, where they combine with cholesterol, triglycerides, and other substances to form chylomicrons. Chylomicrons then pass through to the lymphatic system to be carried to the blood.

Ezetimibe blocks cholesterol absorption into enterocytes and keeps cholesterol from moving through the intestinal wall, as shown below right. Reduced cholesterol absorption from the intestine decreases chylomicron and LDL cholesterol content.

Description

## TABLETS

**Adults.** 10 mg daily.

## Contraindications

Active liver disease or unexplained persistent elevations in hepatic transaminase levels (with concurrent statin use), breastfeeding (with concurrent statin use), hypersensitivity to ezetimibe or its components, pregnancy (with concurrent statin use)

## Interactions

### DRUGS

*cholestyramine:* Reduced effects of ezetimibe

*cyclosporine:* Increased blood cyclosporine and ezetimibe levels

*fibrates:* Increased cholesterol excretion into the bile, leading possibly to cholelithiasis

*warfarin*: Possibly altered International Normalized Ratio (INR)

## Adverse Reactions

**CNS:** Depression, dizziness, fatigue, headache, paresthesia

**CV:** Chest pain

**EENT:** Pharyngitis, sinusitis

**GI:** Abdominal pain, cholelithiasis, cholecystitis, diarrhea, elevated enzymes, **hepatitis**, nausea, **pancreatitis**

**HEME:** **Thrombocytopenia**

**MS:** Arthralgia, back or limb pain, elevated CK level, myalgia, myopathy, **rhabdomyolysis**

**RESP:** Cough, upper respiratory tract infection

**SKIN:** **Erythema multiforme**, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, flu-like symptoms, viral infection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Know that all statins are contraindicated in pregnancy. If a statin is combined with ezetimibe, the resulting combination is a contraindication for use during pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- Use with caution only if benefit to mother outweighs potential risk to her breastfed infant.
- Breastfeeding is contraindicated if a statin is given concurrently.

## Nursing Considerations

- Monitor liver enzymes before and during ezetimibe therapy, as ordered.
- Know that ezetimibe should be given 2 hours before or 4 hours after giving bile acid sequestrant or cholestyramine.

## PATIENT TEACHING

- Direct patient to follow a low-cholesterol diet as an adjunct to ezetimibe therapy. Recommend weight loss and exercise programs, as appropriate.
- Tell him to take ezetimibe either 2 hours before or at least 4 hours after it if patient also takes a bile acid sequestrant to prevent drug interactions.
- Advise patient to report unexplained muscle pain, tenderness, or weakness.

**famciclovir**

**Famvir**

## Class and Category

*Pharmacologic class:* Nucleoside analogue

*Therapeutic class:* Antiviral

## Indications and Dosages

- *To treat recurrent episodes of herpes labialis*

## **TABLETS**

**Immunocompetent adults.** 1500 mg as a single dose at first sign of burning, itching, lesion formation, pain, or tingling.

- *To treat recurrent episodes of genital herpes*

## **TABLETS**

**Immunocompetent adult.** 1,000 mg twice a day for 1 day beginning at the first sign of a recurrent episode (burning, itching, lesion formation, pain, or tingling).

- *To suppress chronic recurrent episodes of genital herpes*

## **TABLETS**

**Immunocompetent adults.** 250 mg twice daily.

- *To treat herpes zoster*

## **TABLETS**

**Immunocompetent adults.** 500 mg every 8 hr for 7 days.

- *To treat recurrent episodes of genital or orolabial herpes in HIV-infected patients*

## **TABLETS**

**Adults.** 500 mg twice daily for 7 days beginning at the first sign of a recurrent episode (burning, itching, lesion formation, pain, tingling).

***DOSAGE ADJUSTMENT*** For patient with renal impairment, dosage decreased and/or dosage interval increased depending on what patient's creatinine clearance level is at

the time of treatment and the herpes condition being treated.

## Mechanism of Action

Selectively inhibits herpes viral DNA synthesis and replication.

## Contraindications

Hypersensitivity to famciclovir or its components, use of penciclovir cream

## Interactions

### DRUGS

*drugs eliminated by active renal tubular secretion such as probenecid*: Possibly increased plasma concentration of famciclovir, with increased risk of adverse reactions

## Adverse Reactions

**CNS:** Confusion, dizziness, fatigue, hallucinations, headache, migraine, paresthesia, **seizures**, somnolence

**CV:** Hypersensitivity vasculitis, palpitations

**GI:** Abdominal pain, cholestatic jaundice, diarrhea, elevated bilirubin or liver or pancreatic enzymes, flatulence, nausea, vomiting

**GU:** **Acute renal failure**, dysmenorrhea, elevated serum creatinine

**HEME:** Anemia, **leukopenia**, **neutropenia**, **thrombocytopenia**

**SKIN:** Erythema multiforme, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

**Other:** Anaphylaxis, angioedema

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-669-6682.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cautiously in patients with renal impairment because of the risk of acute renal failure and hepatic impairment, because conversion of famciclovir to its active metabolite may be impaired, resulting in a lower plasma concentration and possibly decreased effectiveness of the drug.

**WARNING** Be aware that dosage adjustment must be made in patients with renal impairment. Acute renal failure has occurred in patients with underlying renal disease who have received inappropriately high doses of famciclovir for their level of renal function.

- Know that famciclovir therapy should be started as soon as possible after the onset of a herpes-related condition. Signs and symptoms to be alert

for include patient complaints of burning, itching, pain, or tingling or appearance of a lesion.

- Monitor patient's liver and renal function closely, and laboratory test values as ordered.

## **PATIENT TEACHING**

- Remind patient that famciclovir should be initiated as soon as possible after a recurrent onset of a herpes-related condition exhibited by sensations of burning, itching, pain, or tingling or when a lesion has appeared.

**WARNING** Tell patient with renal impairment to remind prescriber of this condition when famciclovir is prescribed and when dosage adjustments are made.

**WARNING** Advise patient to get immediate emergency medical treatment if she develops any signs of an allergic reaction, such as difficulty breathing, hives, or swelling of face, lips, tongue, or throat.

- Inform patient that famciclovir is not a cure for herpes. Because genital herpes is a sexually transmitted disease, instruct patient to avoid contact with lesions or intercourse when lesions and/or symptoms are present, to avoid infecting partners. Remind patient, however, that genital herpes is frequently transmitted in the absence of symptoms and therefore patient should always engage in safe sex practices.
- Instruct patient to notify prescriber at once if she experience serious adverse reactions such as confusion, feeling short of breath, increased thirst, pounding heartbeats, swelling, urinating less than usual or not at all, weakness, or weight gain.
- Alert patient that famciclovir does contain lactose and famciclovir usage should be discussed with patients who experience lactose intolerance or who have galactose intolerance or glucose-galactose malabsorption.
- Inform mothers that breastfeeding is not recommended during famciclovir therapy.

# famotidine

**Pepcid, Pepcid AC**

## Class and Category

*Pharmacologic class:* Histamine-2 blocker

*Therapeutic class:* Antiulcer agent

## Indications and Dosages

- *To provide short-term treatment of active duodenal ulcer*

### ORAL SUSPENSION

**Adults.** 40 mg daily at bedtime or 20 mg twice daily up to 8 wk.

### TABLETS

**Adults and children weighing 40 kg (88 lb) or greater.** 40 mg once daily at bedtime or 20 mg twice daily up to 8 wk.

- *To prevent recurrence of duodenal ulcer*

### ORAL SUSPENSION, TABLETS

**Adults.** 20 mg daily at bedtime up to 1 yr.

- *To provide short-term treatment for active, benign gastric ulcer*

### ORAL SUSPENSION

**Adults.** 40 mg daily at bedtime up to 8 wk.

## TABLETS

**Adults and children weighing 40 kg (88 lb) or more.**  
40 mg daily at bedtime up to 8 wk..

➤ *To treat gastroesophageal reflux disease (GERD)*

## ORAL SUSPENSION

**Adults.** 20 mg twice daily for up to 6 wk.

**Children ages 1 to 17.** 1 mg/kg daily in divided doses twice daily 6 to 12 wk. *Maximum:* 40 mg daily.

## Mechanism of Action

In normal digestion, parietal cells in the gastric epithelium secrete hydrogen ( $H^+$ ) ions, which combine with chloride ions ( $Cl^-$ ) to form hydrochloric acid (HCl), as shown below left. However, HCl can inflame, ulcerate, and perforate gastric and intestinal mucosa normally protected by mucus. Famotidine, an  $H^2$ -receptor antagonist, reduces HCl formation by preventing histamine from binding with  $H^2$  receptors on the surface of parietal cells, as shown below right. By doing so, the drug helps prevent peptic ulcers from forming and helps heal existing ones.

Description

## ORAL SUSPENSION

**Infants age 3 months to 1 year.** 0.5 mg/kg twice daily for up to 8 wk, increased to 1 mg/kg twice daily, if needed.  
*Maximum: 40 mg/day.*

**Infants age less than 3 months.** 0.5 mg/kg once daily for up to 8 wk, increased to 1 mg/kg once daily, as needed.

- *To treat symptomatic nonerosive GERD*

## TABLETS

**Adults and children weighing 40 kg (88 lb) or more.**  
 20 mg twice daily up to 6 wk.

- *To treat erosive esophagitis caused by gastroesophageal reflux*

## ORAL SUSPENSION

**Adults.** 20 to 40 mg twice daily for up to 12 wk

- *To treat erosive esophagitis due to GERD diagnosed by endoscopy.*

## ORAL SUSPENSION

**Adults.** 20 or 40 mg twice daily for up to 12 wk.

## TABLETS

**Adults and children weighing 40 kg (88 lb) or more.** 20 or 40 mg twice daily for up to 12 wk.

- *To treat pediatric peptic ulcer disease*

## ORAL SUSPENSION, TABLETS

**Children age 1 to 17 years.** *Initial:* 0.5 mg/kg once daily or 0.25 mg/kg twice daily for 8 wk, increased to 1 mg/kg once daily at bedtime or 0.5 mg/kg twice daily, as needed. *Maximum:* 40 mg/day.

- *To treat gastric hypersecretory conditions, such as Zollinger-Ellison syndrome*

## ORAL SUSPENSION, TABLETS

**Adults.** *Initial:* 20 mg every 6 hr. Dosage adjusted, if needed, based on patient response. *Maximum:* 160 mg every 6 hr.

- *To treat hospitalized patients with intractable ulcers or pathological hypersecretory conditions; to treat patients who are unable to take oral medication*

## I.V. INFUSION OR INJECTION

**Adults.** 20 mg every 12 hr, infused over 15 to 30 min or injected over at least 2 min.

**Children ages 1 to 16.** *Initial:* 0.25 mg/kg every 12 hr, infused over 15 to 30 min or injected over at least 2 min. *Maximum:* 40 mg daily.

- *To prevent heartburn and indigestion*

## TABLETS

**Adults.** 10 mg 1 hr before eating. *Maximum:* 20 mg every 24 hr for up to 2 wk.

➤ *To treat heartburn and indigestion*

## TABLETS

**Adults.** 10 mg at onset of symptoms. *Maximum:* 20 mg every 24 hr for up to 2 wk unless prescribed otherwise.

***DOSAGE ADJUSTMENT*** Oral or parenteral dosage reduced or dosing interval increased (to 48 hr), if needed, in patients with renal insufficiency and creatinine clearance less than 60 ml/min.

Route	Onset	Peak	Duration
P.O.	1 hr	1-4 hr	10-12 hr
I.V.	In 30 min	0.5-3 hr	10-12 hr

## Contraindications

Hypersensitivity to famotidine, other H<sub>2</sub>-receptor antagonists, or their components

## Interactions

### DRUGS

*drugs dependent on gastric pH for absorption:* Reduced absorption of these drugs

*tizanidine:* Possibly substantial increase in blood tizanidine levels with increased risk of adverse reactions

## Adverse Reactions

**CNS:** Agitation (infants), anxiety, asthenia, confusion, delirium, depression, dizziness, fatigue, fever, hallucinations, headache, insomnia, lethargy, mental or mood changes, paresthesia, **seizures**, somnolence

**CV:** **Arrhythmias**, **AV block**, palpitations, **prolonged QT interval**

**EENT:** Dry mouth, **laryngeal edema**, taste alteration, tinnitus

**GI:** Abdominal pain, anorexia, cholestatic jaundice, constipation, diarrhea, elevated liver enzymes, **hepatitis**, jaundice, nausea, vomiting

**GU:** Decreased libido, impotence

**HEME:** **Agranulocytosis**, **aplastic anemia**, **leukopenia**, **neutropenia**, **pancytopenia**, **thrombocytopenia**

**MS:** Arthralgia, muscle cramps, musculoskeletal pain, **rhabdomyolysis**

**RESP:** **Bronchospasm**, dyspnea, **interstitial pneumonia**, wheezing

**SKIN:** Acne, alopecia, dry skin, **erythema multiforme**, **exfoliative dermatitis**, flushing, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, hyperuricemia

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Shake famotidine oral suspension vigorously for 5 to 10 seconds before administration.
- Dilute injection form (2 ml) with normal saline solution or other solution to 5 to 10 ml; give I.V. injection over at least 2 minutes. Or, dilute in 100 ml of D<sub>5</sub>W and infuse over 15 to 30 minutes; or infuse premixed injection (20 mg/50 ml normal saline solution) over 15 to 30 minutes.

**WARNING** Be aware that Pepcid AC chewable tablets contain aspartame, which can be dangerous for patients who have phenylketonuria.

- Know that adult patients who have a suboptimal response or an early symptomatic relapse after completing famotidine therapy, should be evaluated for gastric malignancy.

## PATIENT TEACHING

- Instruct patient to store famotidine oral suspension at room temperature (below 86° F [30° C]) and to protect it from freezing. Tell her to shake the bottle vigorously, right before use, for 5 to 10 seconds.
- Instruct patient to carefully chew chewable tablets thoroughly before swallowing.
- Instruct patient who also takes antacids to wait 30 to 60 minutes after taking famotidine, if possible, before taking antacid.
- Caution patient to avoid alcohol and smoking during famotidine therapy because they irritate the stomach and can delay ulcer healing.
- Advise patient to notify prescriber if she develops pain, has trouble swallowing, or if she has bloody vomit or black stools.

- Caution patient not to take famotidine with other acid-reducing products.
- Caution patient, especially the elderly and patients with renal impairment, to avoid hazardous activities until drug's CNS effects are known.

## febuxostat

### Uloric

## Class and Category

*Pharmacologic class:* Xanthine oxidase inhibitor

*Therapeutic class:* Antigout

## Indications and Dosages

- *To treat chronic hyperuricemia in patients with gout, in patients who have an inadequate response to a maximally titrated dose of allopurinol, who are intolerant to allopurinol, or for whom treatment with allopurinol is not advisable*

## TABLETS

**Adults.** *Initial:* 40 mg once daily, increased after 2 wk to 80 mg once daily, if needed.

***DOSAGE ADJUSTMENT*** For patient with severe renal impairment, dosage limited to 40 mg once daily.

Route	Onset	Peak	Duration
P.O.	2-3 days	1-1.5 hr	Unknown

# Mechanism of Action

Inhibits the action of xanthine oxidase, the key enzyme responsible for purine breakdown. Xanthine oxidase catalyzes conversion of xanthine to uric acid, thereby increasing uric acid levels. High uric acid levels cause gout attacks. Inhibiting xanthine oxidase causes uric acid levels to drop, decreasing the risk of gout attack.

# Contraindications

Concurrent use of azathioprine or mercaptopurine, hypersensitivity to febuxostat or its components

# Interactions

## DRUGS

*azathioprine, mercaptopurine, theophylline*: Possibly increased serum levels of these drugs, leading to toxicity

# Adverse Reactions

**CNS:** Aggression, **CVA**, dizziness, hemiparesis, **lacunar infarction**, psychotic behavior, transient ischemic attack

**CV:** Angina, chest pain or discomfort, **ECG abnormalities**, **MI**

**EENT:** Blurred vision, deafness, epistaxis, nasal dryness, paranasal sinus hypersecretion, **pharyngeal edema**, sneezing, taste disturbance, throat irritation, tinnitus

**ENDO:** Breast pain, gynecomastia, hot flashes, **hypoglycemia**

**GI:** Diarrhea, dyspepsia, elevated liver enzymes, GI discomfort, **hepatic failure**, hepatomegaly, jaundice, nausea, vomiting

**GU:** Decreased libido, erectile dysfunction, hematuria, nephrolithiasis, pollakiuria, proteinuria, **renal failure or insufficiency**, tubulointerstitial nephritis, urgency

**HEME:** **Agranulocytosis**, anemia, eosinophilia, **idiopathic thrombocytopenic purpura**, leukocytosis, **leukopenia**, **neutropenia**, **pancytopenia**, splenomegaly, **thrombocytopenia**

**MS:** Arthralgia, joint stiffness or swelling, **rhabdomyolysis**

**RESP:** Upper respiratory tract infection

**SKIN:** Dermatitis, eczema, **erythema multiforme**, flushing, hair color or growth changes, hyperhidrosis, peeling skin, petechiae, photosensitivity, pruritis, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, gout flares, **hypersensitivity reactions**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.

- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that febuxostat therapy isn't recommended for patients in whom rate of urate formation is greatly increased, as in malignancy and its treatment or Lesch-Nyhan syndrome.
- Obtain a liver test panel, as ordered, prior to initiating febuxostat therapy and then periodically thereafter. Monitor patient for signs and symptoms of liver dysfunction such as anorexia, dark urine, fatigue, jaundice, or right upper abdominal discomfort throughout therapy. If signs and symptoms occur or if abnormal liver tests occur, especially an elevated serum alanine aminotransferase level greater than 3 times the upper normal limit, notify prescriber and expect drug to be withheld until underlying cause is determined. If no other cause can be found other than febuxostat therapy, expect drug to be discontinued permanently.
- Monitor patient's serum uric acid level, as prescribed, to determine drug effectiveness. Expect it to take about 2 weeks for uric acid level to be therapeutically altered. Dose may be increased from 40 to 80 mg daily if target serum uric acid level fails to fall below 6 mg/dl.
- Monitor patient for gout flares, which may occur after therapy is started because of changing serum uric acid levels that result in mobilization of urate from tissue deposits. Expect prescriber to order colchicine or an NSAID when febuxostat therapy starts. If patient has a gout flare-up during treatment, notify prescriber, and expect symptoms to be managed. Know that febuxostat therapy usually isn't discontinued during this time.

**WARNING** Monitor patient with established cardiovascular disease because use of febuxostat increases the risk of death from cardiovascular conditions. Also monitor patient for evidence of cardiovascular thrombosis, such as acute MI or stroke, because drug may increase patient's risk of developing these disorders, which may result in death.

- Assess patient's skin for abnormalities. At first sign of rash or other skin abnormality, notify prescriber and expect drug to be discontinued if serious skin reactions are suspected or occur, because febuxostat may cause severe skin reactions. Also know that patients who have

experienced hypersensitivity reactions to allopurinol may be at increased risk of developing serious skin reactions to febuxostat.

## PATIENT TEACHING

- Inform patient that a gout attack may occur when febuxostat therapy starts and that colchicine or an NSAID may be prescribed, usually along with febuxostat, to treat it.
- Instruct patient to seek immediate emergency care for signs or symptoms of a heart attack or stroke.
- Tell patient that periodic blood tests will be needed to determine drug's effectiveness and to detect adverse effects.
- Advise patient to notify prescriber at first sign of a rash or other skin abnormality.

# felbamate

## Felbatol

## Class and Category

*Pharmacologic class:* Carbamate

*Therapeutic class:* Anticonvulsant

## Indications and Dosages

- *To treat severe partial seizures as monotherapy in patients who don't respond to other drugs and risks of aplastic anemia and/or liver failure is deemed acceptable in light of the benefits*

## ORAL SUSPENSION, TABLETS

**Adults and adolescents age 14 and over.** *Initial:* 1,200 mg daily in divided doses 3 times daily or 4 times daily. Dosage increased in 600 mg increments every 2 wks, as needed. *Maximum:* 3,600 mg daily.

- *As adjunct to treat severe partial seizures in patients who respond inadequately to alternative treatments and risks of aplastic anemia and/or liver failure is deemed acceptable in light of the benefits*

## **ORAL SUSPENSION, TABLETS**

**Adults and adolescents age 14 and over.** *Week 1:* 1,200 mg daily in 3 or 4 divided doses while other anticonvulsant drugs decreased by 20 to 33%. *Week 2:* Dosage increased to 2,400 mg daily in 3 or 4 divided doses and additional reductions made with other anticonvulsant drugs, as needed. *Week 3:* Dosage increased to 3,600 mg daily in 3 or 4 divided doses with reductions made with other anticonvulsant drugs as needed. *Maximum:* 3,600 mg daily.

- *As adjunct to treat severe generalized or partial seizures associated with Lennox-Gastaut syndrome in children and risks of aplastic anemia and/or liver failure is deemed acceptable in light of the benefits*

## **ORAL SUSPENSION, TABLETS**

**Children ages 2 to 14.** *Initial:* 15 mg/kg daily in 3 or 4 divided doses while other anticonvulsant drug dosages decreased by 20%. Dosage further increased by 15 mg/kg daily every wk. *Maximum:* 45 mg/kg daily.

***DOSAGE ADJUSTMENT*** Dosage reduced by 50% in patients with renal impairment.

## **Mechanism of Action**

May exert anticonvulsant effects by antagonizing the amino acid glycine. When glycine binds to N-methyl-D-aspartate (NMDA) receptors in the CNS, the frequency at which receptor-gated calcium ion channels open is increased—an important factor in initiating seizures. Felbamate may raise the seizure threshold by blocking NMDA receptors so glycine can't bind to them.

## Contraindications

Hepatic dysfunction; history of blood dyscrasias; hypersensitivity to felbamate, other carbamates, or their components

## Interactions

### DRUGS

*carbamazepine*: Decreased blood carbamazepine level and increased felbamate clearance, resulting in decreased blood felbamate level

*fosphenytoin, phenytoin*: Increased blood phenytoin level and increased felbamate clearance, resulting in decreased blood felbamate level

*oral contraceptives*: Possibly decreased effectiveness of oral contraceptives

*phenobarbital*: Decreased blood felbamate level, increased blood phenobarbital level and risk of adverse effects

*valproic acid*: Increased blood valproic acid level and increased risk of adverse effects

## Adverse Reactions

**CNS:** Abnormal gait, aggressiveness, agitation, anxiety, dizziness, drowsiness, fever, headache, insomnia, mood

changes, **suicidal ideation**, tremor

**EENT:** Altered taste, diplopia, rhinitis

**GI:** Abdominal pain, anorexia, constipation, diarrhea, elevated liver function test results, **hepatic failure**, indigestion, nausea, vomiting

**HEME:** **Aplastic anemia**, **leukopenia**, **pancytopenia**, **thrombocytopenia**

**RESP:** Upper respiratory tract infection

**SKIN:** Photosensitivity, purpura, rash

**Other:** **Anaphylaxis**, lymphadenopathy, weight loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Check liver function test results before starting felbamate, and expect to check results every 1 to 2 weeks during treatment. Notify prescriber immediately and expect to stop drug if results are abnormal.

**WARNING** Assess for signs of aplastic anemia and bone marrow depression. Signs may not appear until several months after therapy begins. Expect to stop felbamate if bone marrow depression develops.

- Know that if patient receives adjunctive therapy, expect adverse reactions may be expected to resolve as other anticonvulsant dosages decrease.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.

## **PATIENT TEACHING**

- Direct patient to shake suspension before using and to use a calibrated spoon or container to measure each dose.
- Instruct patient to store oral suspension and tablets at room temperature.
- Urge patient to protect skin from sun and to avoid sunlamps and tanning booths.
- Explain that dizziness and drowsiness may occur. Advise her to avoid hazardous activities until drug's CNS effects are known.
- Warn patient not to stop drug abruptly.
- Advise patient to return for ordered liver function tests and to report dark urine and yellow skin or eyes to prescriber.
- Instruct patient to tell prescriber if she experiences bleeding, fatigue, or infection.
- Advise patient to carry medical identification that indicates condition and therapy.
- Discuss alternate contraceptive methods with female patients because felbamate decreases oral contraceptive effectiveness.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report any concerns immediately.
- Encourage female patient who becomes pregnant while taking felbamate to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that this registry is collecting information about the safety of antiepileptic drugs during pregnancy.

# felodipine

**Plendil**

## Class and Category

*Pharmacologic class:* Calcium channel blocker

*Therapeutic class:* Antihypertensive

## Indications and Dosages

- *To manage mild to moderate essential hypertension alone or with other antihypertensives*

### E.R. TABLETS

**Adults.** *Initial:* 5 mg daily. Dosage adjusted every 2 wk.

*Maintenance:* 2.5 to 10 mg daily based on patient response.

***DOSAGE ADJUSTMENT*** For patients who are over age 65 or have impaired liver function, initial dosage reduced to 12.5 mg daily.

Route	Onset	Peak	Duration
P.O.	2-5 hr	Unknown	16-24 hr

## Mechanism of Action

May slow the movement of extracellular calcium into myocardial and vascular smooth-muscle cells by deforming calcium channels in cell membranes, inhibiting ion-controlled gating mechanisms, and interfering with calcium release from the sarcoplasmic reticulum. The effect of

these actions is a decrease in intracellular calcium ions, which inhibits contraction of smooth-muscle cells and dilates coronary and systemic arteries. As with other calcium channel blockers, felodipine's actions result in increased oxygen to the myocardium and reduced afterload, blood pressure, and peripheral resistance.

## Contraindications

Hypersensitivity to felodipine, other dihydropyridine calcium channel blockers, or their components

## Interactions

### DRUGS

*antihypertensives*: Increased risk of hypotension

*cimetidine, erythromycin itraconazole, ketoconazole*:

Increased felodipine level and effects

*clarithromycin*: Increased risk of acute kidney injury in elderly patients

*CYP3A4 inducers (long-term) such as carbamazepine,*

*phenobarbital, phenytoin*: Decreased felodipine levels

*CYP3A4 substrates such as benzodiazepines, flecainide,*

*imipramine, propafenone, terfenadine, theophylline*:

Increased felodipine plasma concentrations

*metoprolol*: Possible altered pharmacokinetics of metoprolol

*tacrolimus*: Possibly increased blood tacrolimus level and risk of adverse effects

### ACTIVITIES

*alcohol use*: Induced vasodilation enhancing the effects of felodipine and increasing risk of hypotension

## FOODS

*grapefruit juice*: Significant increase in felodipine levels, increasing risk of hypotension

*high carbohydrate or fat diet*: Significantly increased felodipine bioavailability with increased risk of hypotension

## Adverse Reactions

**CNS**: Asthenia, dizziness, drowsiness, fatigue, headache, paresthesia, syncope, weakness

**CV**: Chest pain, **hypotension**, palpitations, peripheral edema, tachycardia

**EENT**: Gingival hyperplasia, pharyngitis, rhinitis

**GI**: Abdominal cramps, constipation, diarrhea, indigestion, nausea

**HEME**: **Agranulocytosis**

**MS**: Back pain

**RESP**: Cough

**SKIN**: Flushing, rash

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm. However, animal studies have shown the possibility of digital anomalies.
- Drug is contraindicated during pregnancy.

### LABOR & DELIVERY

- Animal studies have shown a prolongation of parturition with difficult labor when higher than normal dosages of drug were given.
- Animal studies also have shown an increased risk of fetal and early postnatal deaths when higher than normal dosages of drug were given.

## LACTATION

- It is not known if drug is present in breast milk.
- Drug is contraindicated with breastfeeding.

## REPRODUCTION

- Women of childbearing age should use effective contraception throughout drug therapy.

## Nursing Considerations

- Use felodipine cautiously in patients with heart failure or reduced ventricular function.
- Monitor blood pressure during dosage titration and throughout felodipine therapy, especially in elderly patients.
- Felodipine bioavailability increases up to twofold when taken with grapefruit juice.

**WARNING** Be aware that felodipine may cause severe hypotension with syncope, which may lead to reflex tachycardia. This can precipitate angina in patients with coronary artery disease or a history of angina.

- Watch for signs of overdose, such as excessive peripheral vasodilation, marked hypotension, and, possibly, bradycardia. If they appear, place patient in supine position with legs elevated and give I.V. fluids, as ordered. Expect to give I.V. atropine for bradycardia.

## PATIENT TEACHING

- Instruct patient to swallow tablets whole and not to crush or chew them.
- Caution patient not to alter her intake of grapefruit juice during therapy.
- Advise patient to store felodipine at room temperature and to protect it from light.
- Instruct patient to monitor her pulse rate and blood pressure.
- Teach patient how to minimize gingival hyperplasia.
- Advise patient to notify prescriber immediately if she has palpitations, pronounced dizziness, or swelling of hands or feet.
- Instruct women of childbearing age to use effective contraception during drug therapy.

## fenofibrate

**Antara, Fenoglide, Lipofen, Lofibra, Tricor, Triglide**

## fenofibrate choline

**Trilipix**

## fenofibric acid

**Fibricor**

## Class and Category

*Pharmacologic class:* Fibrate

*Therapeutic class:* Antilipemic

# Indications and Dosages

- *To treat primary hypercholesterolemia or mixed hyperlipidemia*

## **CAPSULES (LIPOFEN)**

**Adults.** 150 mg daily with food.

## **CAPSULES (LOFIBRA)**

**Adults.** 200 mg daily with food.

## **CAPSULES (ANTARA)**

**Adults.** 90 mg daily.

## **DELAYED-RELEASE CAPSULES (TRILIPIX)**

**Adults.** 135 mg daily.

## **TABLETS (TRICOR)**

**Adults.** 160 mg daily.

## **TABLETS (FIBRICOR)**

**Adults.** 105 mg daily.

## **TABLETS (TRIGLIDE)**

**Adults.** 160 mg daily.

## **TABLETS (FENOGLIDE)**

**Adults.** 120 mg daily.

- *As adjunct to diet to treat severe hypertriglyceridemia*

## **CAPSULES (ANTARA)**

**Adults.** *Initial:* 30 to 90 mg daily, increased as needed at 4- to 8-wk intervals. *Maximum:* 90 mg daily.

### **CAPSULES (LIPOFEN)**

**Adults.** *Initial:* 50 to 150 mg daily with food, increased as needed at 4- to 8-wk intervals. *Maximum:* 150 mg daily with food.

### **DELAYED-RELEASE CAPSULES (TRILIPIX)**

**Adults.** *Initial:* 45 to 135 mg once daily, increased as needed at 4- to 8-wk intervals. *Maximum:* 135 mg daily.

### **TABLETS (FIBRICOR)**

**Adults.** *Initial:* 35 to 105 mg daily, increased as needed at 4- to 8-wk intervals. *Maximum:* 105 mg daily.

### **TABLETS (TRICOR)**

**Adults.** *Initial:* 54 to 160 mg daily, increased as needed at 4- to 8-wk intervals. *Maximum:* 160 mg daily.

### **TABLETS (TRIGLIDE)**

**Adults.** 160 mg daily, *Maximum:* 160 mg daily.

### **TABLETS (FENOGLIDE)**

**Adults.** 40 to 120 mg daily, increased as needed at 4- to 8-wk intervals. **Maximum:** 120 mg daily.

### **TABLETS (LOFIBRA)**

**Adults.** 67 to 200 mg daily with food, increased as needed at 4- to 8-wk intervals. **Maximum:** 200 mg daily.

**DOSAGE ADJUSTMENT** For patients with mild to moderate renal impairment or elderly patients, dosage limited for all indications to lowest dosage prescribed for treatment of severe hypertriglyceridemia once daily with increase only after drug's therapeutic and renal effects are known.

Route	Onset	Peak	Duration
P.O.	6-8 wk	Unknown	Unknown

## Mechanism of Action

May increase the lipolysis of triglyceride-rich lipoproteins and decrease the synthesis of fatty acids and triglycerides by enhancing the activation of lipoprotein lipase and acyl-coenzyme A synthetase. Fenofibrate also may:

- increase hepatic elimination of cholesterol as bile salts
- promote the catabolism of larger, less dense LDLs with a high-binding affinity for cellular LDL receptors.

## Contraindications

Active liver disease; breastfeeding; Active liver disease; breastfeeding; gallbladder disease; hypersensitivity to fenofibrate, fenofibric acid, or their components; severe renal impairment

## Interactions

### DRUGS

*bile acid sequestrants*: Decreased fenofibrate absorption

*colchicine*: Increased risk of myopathy and rhabdomyolysis

*coumarin anticoagulants*: Increased risk of bleeding

*immunosuppressants such as cyclosporine and tacrolimus:*  
Increased risk of nephrotoxicity

## **FOODS**

*all foods:* Increased fenofibrate bioavailability when given in capsule form

## **Adverse Reactions**

**CNS:** Asthenia, fatigue, headache

**CV:** **Deep vein thrombosis**, severely depressed HDL cholesterol levels

**EENT:** Rhinitis

**GI:** Abdominal pain, cholelithiasis, **cirrhosis**, constipation, diarrhea, elevated liver enzymes, **hepatitis**, nausea, **pancreatitis**

**GU:** **Acute renal failure**, increased serum creatinine level, **renal failure**

**HEME:** **Agranulocytosis**; anemia; decreased hematocrit or hemoglobin, levels; **leukopenia**, **thrombocytopenia**

**MS:** Arthralgia, back pain, elevated creatinine phosphokinase, muscle spasms, myalgia, myopathy, myositis, **rhabdomyolysis**

**RESP:** **Interstitial lung disease**, **pulmonary embolus**

**SKIN:** Photosensitivity, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **delayed hypersensitivity reactions**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, flu-like symptoms

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Drug is contraindicated in breastfeeding women.

# Nursing Considerations

- Be aware that all drugs that increase serum triglycerides, such as beta blockers, estrogens, and thiazides, should be stopped, and baseline lipid levels obtained before starting fenofibrate.
- Be aware that some brands such as Lipofen and Lofibra need to be given with food to enhance absorption.
- Administer drug 1 hour before or 4 hours after bile acid sequestrants.
- Monitor results of liver function tests. If liver enzyme levels rise to more than 3 times the upper limit of normal and persist, or if the patient develops gallstones, expect to stop drug.
- Monitor patient's renal function as elevations in serum creatinine levels have occurred with fenofibrate therapy.
- Monitor serum cholesterol and triglyceride levels at 4- to 8-week intervals, as ordered. If levels don't decrease after 2 months at maximum dosage, expect therapy to be discontinued.

**WARNING** Monitor patient closely for acute hypersensitivity reactions, including severe rash, and notify prescriber if they occur. Patient may need inpatient corticosteroids. Also monitor patient for delayed cutaneous hypersensitivity reactions that may be

severe and can occur days to weeks after fenofibrate therapy is initiated.

- Assess blood counts periodically, as ordered, during first 12 months of therapy to detect adverse hematologic effects.
- Watch closely for evidence of deep vein thrombosis (pain, redness in extremity, or swelling) or pulmonary embolus (sudden onset of anxiety, restlessness, or shortness of breath) because risk is higher in patients taking fenofibrate. Notify prescriber immediately, and start emergency treatment, as prescribed.

## PATIENT TEACHING

- Emphasize that drug will be effective only if patient carefully follows prescriber's instructions about diet and exercise.
- Instruct patient to take drug with food.
- Instruct patient prescribed tablet form to store the tablets in their original, desiccant-containing bottle and to avoid taking any chipped or broken tablets.
- Advise patient to have laboratory tests, as directed, to determine drug's effectiveness. They typically include liver function tests after 3 to 6 months, hematocrit and hemoglobin levels, and WBC counts periodically during first year.
- Urge patient to notify prescriber immediately about chills, fever, or sore throat, as well as skin changes such as appearance of blisters or a rash. Also urge her to tell prescriber about unexplained muscle pain, tenderness, or weakness, especially if accompanied by fatigue or fever.
- Tell patient to seek emergency treatment if he develops pain, swelling, and redness in his limb or sudden shortness of breath, anxiety, and restlessness.
- Instruct patient to use sunscreen and protective clothing while in sun and to limit time spent in sun because photosensitivity may occur weeks to months after drug is initiated.

**fenofibrate**

**Abstral, Actiq, Fentora, Lazanda,  
Sublimaze, SUBSYS**

**fentanyl transdermal  
system**

**Duragesic**

## **Class, Category, and Schedule**

*Pharmacologic class:* Opioid

*Therapeutic class:* Opioid analgesic

*Controlled substance schedule:* II

## **Indications and Dosages**

➤ *To provide surgical premedication*

### **I.M. INJECTION (SUBLIMAZE)**

**Adults.** 0.05 to 0.1 mg 30 to 60 min before surgery.

➤ *As adjunct to regional anesthesia*

### **I.V. OR I.M. INJECTION (SUBLIMAZE)**

**Adults.** 0.05 to 0.1 mg I.M. or slow I.V. over 1 to 2 min.

➤ *To induce and maintain anesthesia*

### **I.M. INJECTION (SUBLIMAZE)**

**Children age 2 to 12.** 2 to 3 mcg/kg.

- *To manage postoperative emergence delirium, pain, or tachypnea in postanesthesia care unit*

### **I.M. INJECTION (SUBLIMAZE)**

**Adults.** 0.05 to 0.1 mg. Repeated in 1 to 2 hr, if needed.

- *As adjunct to general anesthesia*

### **I.V. INJECTION (SUBLIMAZE)**

**Adults.** *For low-dose therapy:* 0.002 mg/kg followed by 0.002 mg/kg, as needed. *For moderate-dose therapy:* 0.002 to 0.02 mg/kg, followed by 0.025 to 0.1 mg, as needed. *For high-dose therapy:* 0.02 to 0.05 mg/kg followed by 0.025 mg to one-half initial loading dose, as needed. I.V. injection given slowly over 1 to 2 min.

- *To treat breakthrough pain in cancer patients who are receiving around-the-clock opioid therapy and have developed tolerance to it*

### **TRANSMUCOSAL LOZENGE (ACTIQ)**

**Adults.** *Initial:* 200 mcg placed between cheek and gum for 15 min followed by second dose 15 min after first dose ends, as needed. Dosage increased according to patient's needs. *Maximum:* 2 doses of same strength per episode with at least 4 hr between episodes treated.

### **SUBLINGUAL TABLETS (ABSTRAL)**

**Adults.** *Initial:* 100 mcg followed by second dose 30 min after first dose, if needed. Dosage increased in 100-mcg increments, as needed, until 400-mcg dosage reached, then increased in increments of 200 mcg, as needed, until maximum dosage of 800 mcg per dose is reached.

*Maximum:* 800 mcg given twice 30 min apart per episode

of breakthrough pain; dosage interval between episodes of breakthrough pain must be at least 2 hr; only four episodes of breakthrough pain treated per day.

## **BUCCAL TABLETS (FENTORA)**

**Adults.** *Initial:* 100 mcg buccal tablet placed between upper cheek and gum, followed by second dose 30 min after first dose, as needed. Dosage increased to 200 mcg (placing one tablet on each side of mouth in buccal cavity), as needed. Further increased, as needed, to 400 mcg (placing two tablets on each side of mouth in buccal cavity). Further titration done in multiples of 200 mcg, if needed, until maximum dose of 800 mcg per dose is reached. *Maximum:* 800 mcg given twice 30 min apart 4 times daily with at least 4 hr between each episode treated.

## **NASAL SPRAY (LAZANDA)**

**Adults.** *Initial:* 100 mcg. Increased, as needed, to 200 mcg, then 300 mcg, then 400 mcg, then 600 mcg, and finally to 800 mcg with doses spaced at least 2 hr apart. *Maximum:* 800 mcg 4 times daily with a dosing interval of at least 2 hr between each episode.

## **SUBLINGUAL SPRAY (SUBSYS)**

**Adults.** *Initial:* 100 mcg followed by 100 mcg 30 minutes later, if needed. Increased, as needed, to 200 mcg, then 400 mcg, then 600 mcg, then 800 mcg, then 1,200 mcg, then 1,600 mcg with doses spaced at least 4 hr apart. A second dose of same strength may be taken 30 minutes after the first dose, as needed and counted as 1 breakthrough episode. *Maximum:* 1,600 mcg given twice 30 minutes apart 4 times daily with doses spaced at least 4 hr apart.

- *To relieve severe chronic pain in opioid-tolerant patient who doesn't respond to less potent drugs and requires around-the-clock opioid administration for an extended time*

## TRANSDERMAL SYSTEM (DURAGESIC)

**Adults and children age 2 and over.** *Initial:* Highly individualized and based on current opioid therapy. Each patch may be worn for 48 to 72 hr. Dosage increased after first 72 hr and then after no less than two 3-day applications, as needed. For more than 100 mcg/hr, more than one patch used.

**DOSAGE ADJUSTMENT** For cachectic, debilitated or elderly patients, initial dosage should not exceed 25 mcg/hr, unless patient is already receiving more of an equivalent dose of another opioid. For patients receiving long-term opioid therapy, dosage adjusted based on previous day's drug requirement. For patients with mild to moderate hepatic or renal failure, initial dosage decreased by 50%.

Route	Onset	Peak	Duration
I.V.	1-2 min	3-5 min	30-60 min
I.M.	7-15 min	20-30 min	1-2 hr
Trans-dermal	12-24 hr	Unknown	Over 72 hr

## Mechanism of Action

Binds to opioid receptor sites in the CNS, altering perception of and emotional response to pain by inhibiting ascending pain pathways. Fentanyl may alter neurotransmitter release from afferent nerves responsive to painful stimuli, and it causes respiratory depression by acting directly on respiratory centers in the brain stem.

## Contraindications

*All forms:* Hypersensitivity to fentanyl, alfentanil, sufentanil or their components; intermittent pain; opioid nontolerance; significant respiratory depression; treatment of mild to moderate pain responsive to nonopioid drugs; upper airway obstruction

*Transdermal form:* Hypersensitivity to adhesives; management of post-operative pain or pain that may be acute, intermittent, or mild, or pain in patients requiring opioid therapy for a short period of time; patients who are not opioid-tolerant

*Transmucosal form:* Acute or chronic pain, including postoperative pain

## Interactions

*anticholinergics:* Increased risk of severe constipation and urinary retention

*antimigraine agents; cyclobenzaprine; dextromethorphan; dolasetron; granisetron; linezolid; MAO inhibitors;*

*metaxalone; methylene blue (I.V.); ondansetron;*

*palonosetron; selected psychiatric drugs such as*

*amoxapine, buspirone, lithium, mirtazapine, nefazodone,*

*trazodone, vilazodone; selective serotonin reuptake*

*inhibitors; serotonin-norepinephrine reuptake inhibitors;*

*St. John's wort; tramadol; tricyclic antidepressants;*

*triptans; tryptophan:* Increased risk of serotonin syndrome

*benzodiazepines, CNS depressants, muscle relaxants, other*

*opioids, sedating antihistamines, tricyclic antidepressants:*

Increased risk of sedation and somnolence and severe respiratory depression

*buprenorphine, butorphanol, nalbuphine, pentazocin:*

Decreased analgesic effect of fentanyl and possibly

precipitation of withdrawal symptoms

*CYP3A4 inducers such as barbiturates, carbamazepine, efavirenz, glucocorticoids, modafinil, nevirapine, oxcarbazepine, phenytoin, pioglitazone, rifabutin, rifampin, St. John's wort, troglitazone:* Possibly induced metabolism and increased clearance of fentanyl with decreased effectiveness and potential development of withdrawal syndrome in dependent patients

*CYP3A4 inhibitors such as amiodarone, amprenavir, aprepitant, cimetidine, clarithromycin, diltiazem, erythromycin, fluconazole, fosamprenavir, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin, troleandomycin, verapamil:* Possibly increased opioid effect, leading to increased or prolonged adverse effects, including severe respiratory depression

*diuretics:* Possibly decreased efficacy of diuretics

*MAO inhibitors:* Possibly unpredictable or fatal effects if taken within 14 days

## **FOODS**

*grapefruit juice:* Increased blood fentanyl level

## **ACTIVITIES**

*alcohol use:* Increased serum fentanyl level, possibly resulting in fatal overdose from CNS and respiratory depression and hypotension

## **Adverse Reactions**

**CNS:** Agitation, amnesia, anxiety, asthenia, ataxia, confusion, delusions, depression, dizziness, drowsiness, euphoria, fever, hallucinations, headache, lack of coordination, light-headedness, nervousness, paranoia,

sedation, **seizures**, sleep disturbance, slurred speech, syncope, tremor, weakness, yawning

**CV:** **Asystole**, **bradycardia**, chest pain, edema, **hypotension**, orthostatic hypotension, tachycardia

**EENT:** Blurred vision, dental caries, dry mouth, gum-line erosion, **laryngospasm**, rhinitis, sneezing, tooth loss

**ENDO:** **Adrenal insufficiency (rare)**

**GI:** Anorexia, constipation, elevated serum amylase levels, ileus, indigestion, nausea, spasm of the sphincter of Oddi, vomiting

**GU:** Anorgasmia, decreased libido, ejaculatory difficulty, impotence, infertility, lack of menstruation, urinary hesitancy, urine retention

**RESP:** **Apnea**, **depressed cough reflex**, dyspnea, **hypoventilation**, **respiratory depression**

**SKIN:** Diaphoresis, **exfoliative dermatitis**, localized skin redness and swelling (with transdermal form), pruritus, rash

**Other:** **Anaphylaxis**, drug tolerance, physical or psychological dependence with long-term use, weight loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm. However, prolonged use during pregnancy may cause Neonatal Opioid Withdrawal Syndrome.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Drug may prolong labor.
- Drug crosses the placental barrier and may produce excessive sedation and respiratory depression in the neonate.
- Drug should not be used during labor and delivery.

## LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## Nursing Considerations

**WARNING** Know that fentanyl transdermal system should be used only in patients already receiving opioid therapy and with demonstrated opioid tolerance (taking for a week or longer at least 60 mg of morphine daily, 30 mg of oral oxycodone daily, 8 mg of oral hydromorphone daily, or an equianalgesic dose of another opioid), and require at least a fentanyl dosage of 25 mcg/hour to manage their pain.

- Be aware that opioids like fentanyl should not be given to women during pregnancy and labor and while breastfeeding as the newborn or infant may experience neonatal opioid withdrawal syndrome (NOWS) which may be life-threatening and is exhibited as poor feeding, rapid breathing, trembling, and excessive or high-pitched crying.
- Use with extreme caution in patients with significant chronic obstructive pulmonary disease or cor pulmonale, and in patients having a substantially decreased respiratory reserve, hypoxia, hypercapnia, or preexisting respiratory depression, because even therapeutic doses of fentanyl may decrease respiratory drive in these patients to the point of apnea.
- Use with extreme caution in patients who may be susceptible to the intracranial effects of carbon dioxide retention such as those with brain tumors, head injury, increased intracranial pressure, or impaired consciousness. Monitor these patients closely for signs of sedation and respiratory depression.

- Use caution when titrating fentanyl dosage in elderly, cachectic, and debilitated patients, especially when using I.V. route, because these patients are more sensitive to the drug's effects.
- Use cautiously in patients at risk for opioid abuse, such as those with mental illness or personal or family history of substance abuse. Monitor patient throughout therapy for fentanyl abuse or addiction. Be aware that excessive use of fentanyl may lead to abuse, addiction, misuse, overdose, and possibly death. Monitor patient's intake of drug closely.
- Expect the blood fentanyl level to be prolonged if patient chews or swallows the transmucosal form because drug is absorbed slowly from GI tract.

**WARNING** Never apply a transdermal patch if seal has been broken or patch has been cut, damaged, or changed because excessive exposure could occur, resulting in possibly fatal fentanyl overdose.

- Be aware that 100 mcg of fentanyl is equivalent in potency to 10 mg of morphine.
- Know that to achieve optimum pain control with the lowest possible fentanyl dose, also plan to give a nonopioid analgesic, such as acetaminophen, as prescribed.
- Be aware that fentanyl should only be used concomitantly with benzodiazapines or other CNS depressants in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of opioid to be limited. Monitor patient closely for signs and symptoms of a decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

**WARNING** Monitor patient's respiratory status closely, especially during the first 24 to 72 hours after therapy starts or with dosage increases, because severe hypoventilation may occur without warning at any time during therapy. Patients at increased risk include the elderly, cachectic, or debilitated patients. Respiratory depression can occur in patients even if the drug is not misused or abused. Be aware that significant amounts of fentanyl can be absorbed from the skin for 24 hours

or more after a transdermal patch is removed. Monitor patient for at least 72 hours after patch has been removed for respiratory depression. Have emergency equipment available including an opioid antagonist.

- Monitor cancer patients receiving sublingual spray form of fentanyl closely for oral mucositis because exposure to the drug in this form has been found to be greater than in patients without mucositis. If Grade 1 mucositis is present, the risk of respiratory or CNS depression increases, especially when therapy is initiated. Expect to avoid use of sublingual spray in cancer patients with Grade 2 mucositis or higher.
- Monitor patient closely who is receiving concurrent CYP3A4 inhibitor therapy along with fentanyl because these drugs may result in an increase in plasma fentanyl concentrations, which could increase or prolong adverse drug effects and may cause sedation and potentially fatal respiratory depression. Notify prescriber immediately, if present. Be aware that discontinuation of CYP3A4 inducers can result in a fatal overdose of fentanyl. Monitor these patients closely as well.

**WARNING** Know that many drugs may interact with opioids like fentanyl to cause serotonin syndrome. Monitor patient closely for signs and symptoms such as agitation, diaphoresis, diarrhea, fever, hallucinations, labile blood pressure, muscle twitching or stiffness, nausea, shakiness, shivering, tachycardia, trouble with coordination, or vomiting. Notify prescriber at once because serotonin syndrome may be life-threatening. Be prepared to discontinue drug, if possible and ordered, and provide supportive care.

- Monitor patient for adrenal insufficiency. Although rare, it can be life-threatening. Monitor patient for anorexia, dizziness, fatigue, hypotension, nausea, vomiting, or weakness. Notify prescriber if adrenal insufficiency is suspected and expect diagnostic testing to be done. If diagnosis is confirmed, expect to administer corticosteroids and wean patient off fentanyl, if possible.
- Know that to prevent withdrawal symptoms after long-term use, expect to taper drug dosage gradually, as prescribed. Assess patient for withdrawal symptoms after dosage reduction or conversion to another opioid analgesic.

- Monitor patient who is receiving the drug via a transdermal system and who develops a fever for opioid adverse effects because a fever may increase fentanyl release from the system and increase skin permeability. If symptoms occur, notify prescriber and anticipate dosage may be decreased.
- Be aware that for a patient with bradycardia, implement cardiac monitoring, as ordered, and assess heart rate and rhythm frequently during fentanyl therapy because drug may further slow heart rate.

**WARNING** Expect respiratory depressant effects to last longer than analgesic effects. Also be prepared for residual drug to potentiate effects of subsequent doses. Residual drug can be detected for at least 6 hours after I.V. dose and 17 hours after other forms. Monitor patient closely for at least 24 hours after therapy ends.

**WARNING** Assess patient for evidence of overdose, such as cardiopulmonary arrest, hypoventilation, pupil constriction, respiratory and CNS depression, seizures, and shock. Give naloxone (possibly in repeated doses), as prescribed. Be prepared to assist with endotracheal intubation and mechanical ventilation and to provide fluids.

- Monitor blood glucose level of diabetic patient receiving transdermal fentanyl because each unit contains about 2 g of sugar.

**WARNING** Do not substitute Actiq, Lazanda, or Subsys for any other fentanyl product, and do not substitute for each other. Do not convert dosage to or from other products on a mcg-per-mcg basis because doing so may result in a fatal overdose.

## **PATIENT TEACHING**

- Warn patient not to take more drug than prescribed and not to take it longer than absolutely needed because excessive or prolonged use can lead to abuse, addiction, misuse, overdose, and possibly death.

- Instruct patient to avoid alcohol and other CNS depressants including benzodiazepines during fentanyl therapy unless prescribed.
- Advise patient not to stop taking drug unless directed by prescriber because withdrawal symptoms may occur. Warn against increasing dose or frequency without consulting prescriber because drug can cause dependency.
- For transdermal form, instruct patient to choose a site with intact (not irritated or irradiated) skin on a flat surface, such as the chest, back, flank, or upper arm, and, if appropriate, to clip, not shave, hair from the site and clean it with water (no soaps, lotions, oils, or alcohol). After site preparation, instruct patient to press patch firmly in place with palm of hand for 30 seconds, making sure edges are sealed. Tell her to wash her hands immediately after application with soap and water. If patch loosens, tell her to tape edges down but not cover the entire patch. If more than one patch is needed, the edges shouldn't touch or overlap. Instruct patient to remove patch after 72 hours, fold it in half with adhesive sides together, and flush it down the toilet. Remind her not to reuse a site for at least 3 days. Warn patient to avoid accidental secondary exposure to the drug with someone else through contact with unwashed or unclothed application sites. Examples include transfer of a patch from an adult's body to a child while hugging, sharing the same bed as the patient, accidentally sitting on a patch, and possible accidental exposure of a caregiver's skin to the medication in the patch while applying or removing the patch.
- Warn patient never to apply transdermal patch if seal has been broken or the patch has been cut, damaged, or changed in any way because drug may be released too rapidly. Also warn patient not to expose the application site and surrounding area to direct external heat sources, such as heating pads or electric blankets, heat or tanning lamps, saunas, hot tubs, and heated water beds, while wearing the patch. She should also avoid hot baths or sunbathing because increased body temperature may increase fentanyl release, resulting in a possible overdose. If she develops a fever or becomes overheated from strenuous exercise while wearing a patch, she should contact the prescriber immediately.
- For Actiq transmucosal form, instruct patient to open the package just before use and to save plastic cap for discarding the unused part of the lozenge. Tell her to place lozenge between her cheek and gum and to suck, not chew, it for 15 minutes. Show her how to move lozenge from one side of her mouth to the other using the handle provided separately.
- For Abstral sublingual form, instruct patient to place tablet on the floor of the mouth directly under the tongue immediately after removing tablet from the blister unit. Caution patient not to chew, suck, or swallow the tablet but to allow it to dissolve completely in the mouth. Tell him not to eat or drink anything until the tablet is completely dissolved.

- For transmucosal form, urge patient to see a dentist regularly, to brush teeth and floss after each meal, and to avoid frequent consumption of products high in sugar because of increased risk of dental caries.
- For transmucosal form, inform diabetic patient that each unit contains 2 g of sugar. Instruct her to monitor her blood glucose levels closely.
- For nasal spray (Lazanda), tell patient to prime the device before use by spraying into the pouch 4 sprays in total. To use, insert the nozzle of the Lazanda bottle a short distance (about 1/2 inch or 1 cm) into the nose and point towards the bridge of the nose, tilting the bottle slightly. Have patient press down firmly on the finger grips until he hears a “click” and the number in the counting window advances by 1. Tell patient that the fine mist spray is not always felt on the nasal mucosal membrane and to rely on the audible click and the advancement of the dose counter to confirm a spray has been administered.
- For sublingual spray (Subsys), tell patient to open the blister package with scissors immediately prior to drug use. Tell him never to use a blister package that has been discovered to be open. Instruct him to spray the contents of the unit into his mouth carefully, underneath his tongue.
- Inform patient that long-term use of opioids like fentanyl may decrease sex hormone levels, causing decreased libido, erectile dysfunction, impotence, infertility, or lack of menstruation. Encourage patient to report any such symptoms to prescriber.
- Remind patient to keep used and unused dosage units out of reach of children and to dispose of drug properly. For buccal tablets, patient should flush leftover drug down the toilet when no longer needed. For sublingual spray, remind patient to dispose of any used or unneeded units immediately in the disposal bottle provided with every dispensed carton. For transdermal patch, patient should fold in half and flush down toilet.
- Caution patient that accidentally exposing others to transdermal fentanyl could cause serious adverse reactions that may become life threatening, especially in children, even with one dose. If accidental exposure occurs, the person should remove the patch, wash the area well with water, and seek medical attention.
- Caution patient to avoid hazardous activities until drug’s CNS effects are known.
- Inform patient about potentially fatal additive effects of combining fentanyl with a benzodiazepine. Tell patient to inform all prescribers of fentanyl use.
- Tell patient to increase fiber and fluid intake, unless contraindicated, because drug may cause severe constipation. If it persists or becomes

severe, urge patient to notify prescriber.

- Tell patient not to stop drug abruptly as dosage needs to be tapered to prevent return of pain or withdrawal symptoms.
- Instruct patient to dispose of expired, unwanted, or unused drug by flushing down the toilet if a drug take-back option is not readily available.

## ferric citrate

**Auryxia**

### Class and Category

*Pharmacologic class:* Ferric iron-based phosphate binder

*Therapeutic class:* Phosphate binder

### Indications and Dosages

- *To control serum phosphorus levels in patients with chronic kidney disease on dialysis*

#### **TABLETS**

**Adults.** *Initial:* 2 tablets (420 mg ferric iron, equivalent to 2 g ferric citrate) 3 times a day with meals, increased or decreased by 1 to 2 tablets per day at 1-wk or longer intervals, as needed. *Maximum:* 12 tablets (12 g ferric citrate) daily.

- *To treat iron deficiency anemia in patients with chronic kidney disease not on dialysis*

#### **TABLETS**

**Adults.** 1 tablet (210 ferric iron, equivalent to 1 g ferric citrate) 3 times a day with meals, titrated to achieve and maintain hemoglobin at target levels. *Maximum:* 12 tablets (12 g ferric citrate) daily.

## Mechanism of Action

Binds dietary phosphate in the gastrointestinal (GI) tract and precipitates as ferric phosphate, which is then excreted in the stool. By binding phosphate in the GI tract and decreasing absorption, serum phosphate levels are reduced.

## Contraindications

Hypersensitivity to ferric citrate or its components, iron overload syndromes

## Interactions

### DRUGS

*ciprofloxacin, doxycycline:* Decreased effectiveness of these drugs

## Adverse Reactions

**GI:** Abdominal pain, constipation, diarrhea, discolored stools, nausea, vomiting

**HEME:** Increased serum ferritin and transferrin saturation levels

**RESP:** Cough

**Other:** **Hyperkalemia**

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm. However, an overdose of iron in pregnant women may carry a risk for fetal malformation or spontaneous abortion.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that ferric citrate produces dark stools because of its iron content, but this effect does not affect laboratory tests for occult bleeding.
- Know that iron absorption from ferric citrate therapy may cause an excessive elevation in iron stores. Assess patients' serum ferritin and transferrin saturation levels before initiating ferric citrate therapy, as ordered, and monitor throughout therapy.
- Expect that patients receiving iron intravenously may need a reduction in dose or discontinuation of I.V. iron therapy.

## Patient teaching

- Instruct patient to take ferric citrate exactly as ordered.

**WARNING** Remind patient that accidental overdose of iron-containing products is a leading cause of death in children under age 6. Stress the importance of keeping ferric citrate tablets out of the reach of children. If accidental overdose occurs, the poison control center

should be called and immediate emergency treatment sought for the child.

## ferric maltol

**Accrufer**

### Class and Category

*Pharmacologic class: Iron agent*

*Therapeutic class: Hematinic*

### Indications and Dosages

➤ *To treat iron deficiency*

#### CAPSULES

**Adults.** 30 mg twice daily on an empty stomach until iron stores are replenished.

### Mechanism of Action

Delivers iron for uptake across the intestinal wall and transfer to transferrin and ferritin.

### Contraindications

Hemochromatosis and other iron overload syndromes, hypersensitivity to ferric maltol or its components, repeated blood transfusions

# Interactions

## DRUGS

*dimercaprol*: Possibly increased risk of nephrotoxicity

*oral drugs*: Possibly decreased absorption of these drugs

## Adverse Reactions

**GI:** Abdominal discomfort, distension, pain; constipation; diarrhea; discolored feces; flatulence; increased risk of inflammation in gastrointestinal tract; nausea, vomiting  
**HEME:** Iron overload

## Childbearing Considerations

### PREGNANCY

- Drug is not absorbed systemically and maternal use is not expected to result in fetal exposure.
- Overdose of iron in pregnant women may carry a risk for fetal malformation, gestational diabetes, or spontaneous abortion.

### LACTATION

- It is not known if drug is present in breast milk, but presence is not expected because drug is not absorbed systemically.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that ferric maltol should be avoided in patients with an active inflammatory bowel disease flare, because drug has the potential to increase inflammation in the gastrointestinal tract.

- Be aware that ferric maltol should not be given to patients with evidence of iron overload or patients receiving intravenous iron to avoid excess storage of iron.
- Expect to monitor iron parameters, as ordered, during therapy.

## Patient Teaching

- Instruct patient to take drug as ordered and not break, chew, or open the capsules.
- Inform patient that treatment duration will depend on the severity of iron deficiency but that generally at least 12 weeks of therapy are required. However, treatment will continue as long as necessary until ferritin levels are within normal range.
- Urge patient to keep ferric maltol out of reach of children, as accidental overdose of iron-containing products is a leading cause of fatal poisoning in children under age 6.

## ferrous salts

### ferrous fumarate

***(contains 100 mg of elemental iron per capsule or per 5 ml of oral suspension, 33 mg of elemental iron per chewable tablet or per 5 ml of oral suspension, 106 mg of elemental iron per E.R. capsule, 15 mg of elemental iron per 0.6 ml of oral solution, and 20 to 115 mg of elemental iron per tablet)***

**Femiron, Feostat, Feostat Drops, Ferretts, Fumasorb, Fumerin, Hemocyte, Ircon, Neo-Fer (CAN), Nephro-Fer, Novofumar (CAN), Palafer (CAN), Span-FF**

## **ferrozus carboxymaltose**

**Injectafer**

## **ferrous gluconate**

**Apo-Ferrous Gluconate (CAN), FE-40, Ferate, Fergon, Ferralet, Ferralet Slow Release, Fertinic (CAN), Novoferrogluc (CAN), Simron**

## **ferrous sulfate**

**Feosol, Feratab, Fer-gen-sol, Fer-In-Sol, Fer-Iron, Ferodan, Fero-Grad (CAN), Fero-Gradumet, Ferospace, Ferralyn Lanacaps, Ferra-TD, Feusal Original, Mol-Iron, Novoferrosulfa (CAN), PMS-Ferrous Sulfate (CAN), Slow-Fe**

# iron, carbonyl

## Feosol Natural Release

### Class and Category

*Pharmacologic class:* Hematinic

*Therapeutic class:* Antianemic, nutritional supplement

### Indications and Dosages

- *To prevent iron deficiency based on recommended daily allowances*

**CAPLETS, CAPSULES, CHEWABLE TABLETS, DRIED CAPSULES, DRIED E.R. CAPSULES, DRIED E.R. TABLETS, DRIED TABLETS, ELIXIR, ENTERIC-COATED TABLETS, E.R. CAPSULES, E.R. TABLETS, ORAL SOLUTION, ORAL SUSPENSION, SYRUP, TABLETS**

**Adults age 51 and over.** 8 mg daily.

**Adult females age 19 to 50.** 18 mg daily.

**Adult men age 19 to 50.** 8 mg daily.

**Pregnant women.** 27 mg daily.

**Breastfeeding women.** 9 to 10 mg daily.

**Boys age 14 to 18.** 11 mg daily.

**Girls age 14 to 18.** 15 mg daily.

**Children age 9 to 13.** 8 mg daily.

**Children age 4 to 8.** 10 mg daily.

**Children age 1 to 3.** 7 mg daily.

**Infants age 7 to 12 months.** 11 mg daily.

**Newborns to age 6 months.** 0.27 mg daily.

➤ *To replace iron in deficiency states*

**CAPLETS, CAPSULES, CHEWABLE TABLETS, DRIED CAPSULES, DRIED E.R. CAPSULES, DRIED E.R. TABLETS, DRIED TABLETS, ELIXIR, ENTERIC-COATED TABLETS, E.R. CAPSULES, E.R. TABLETS, ORAL SOLUTION, ORAL SUSPENSION, SYRUP, TABLETS**

**Adults and adolescents.** 300 to 325 mg daily.

*Maintenance:* 325 mg up to 3 times daily for several wk or mo.

**Infants and children.** *For mild to moderate iron deficiency anemia:* 3 mg elemental iron/kg/day in 1 to 2 divided doses. *For severe iron deficiency anemia:* 4 to 6 mg elemental iron/kg/day in 3 divided doses.

**Premature neonates.** 2 to 4 mg elemental iron/kg/day divided every 12 to 24 hr. *Maximum:* 15 mg daily.

➤ *To treat iron deficiency in patients who have an intolerance to oral iron, have had unsatisfactory response to oral iron, or who have non-dialysis-dependent chronic kidney disease*

## **I.V. INFUSION (INJECTAFER), I.V. INJECTION (INJECTAFER)**

**Adults weighing 50 kg (110 lb) or more.** 750 mg followed by second dose of 750 mg given no sooner than 7 days later. I.V. injection given slowly at a rate of 100 mg/min. I.V. infusion given over at least 15 min. *Maximum:* 1,500 mg per course with the 2 doses separated by at least 7 days.

**Adults weighing less than 50 kg (110 lb).** 15 mg/kg followed by second dose of 15 mg/kg given no sooner than

7 days later. I.V. injection given slowly at a rate of 100 mg/min. I.V. infusion given over at least 15 min. *Maximum:* 1,500 mg per course with the 2 doses separated by at least 7 days.

➤ *To provide iron supplementation during pregnancy*

**CAPLETS, CAPSULES, CHEWABLE TABLETS, DRIED CAPSULES, DRIED E.R. CAPSULES, DRIED E.R. TABLETS, DRIED TABLETS, ELIXIR, ENTERIC-COATED TABLETS, E.R. CAPSULES, E.R. TABLETS, ORAL SOLUTION, ORAL SUSPENSION, SYRUP, TABLETS**

**Pregnant women.** 30 mg elemental iron daily.

***DOSAGE ADJUSTMENT*** Dosage increased if needed for elderly patients, who may not absorb iron as easily as younger adults do.

## **Mechanism of Action**

Acts to normalize RBC production by binding with hemoglobin or by being oxidized and stored as hemosiderin or aggregated ferritin in reticuloendothelial cells of the bone marrow, liver, and spleen. Iron is an essential component of hemoglobin, myoglobin, and several enzymes, including catalase, cytochromes, and peroxidase. Iron is needed for catecholamine metabolism and normal neutrophil function.

## **Contraindications**

Hemochromatosis, hemolytic anemias, hemosiderosis, hypersensitivity to iron salts or their components, other anemic conditions unless accompanied by iron deficiency

# Interactions

## DRUGS

*antacids*: Possibly decreased absorption of iron salts

*bisphosphonates, dolutegravir, integrase inhibitors*:

Decreased absorption of these drugs

*dimercaprol*: Increased risk of nephrotoxic effect of iron salts

*levodopa*: Possibly chelation with iron, decreasing levodopa absorption and blood level

*levothyroxine*: Decreased levothyroxine effectiveness and, possibly, hypothyroidism

*methyldopa*: Decreased methyldopa absorption and efficacy

*quinolones, tetracyclines*: Decreased effectiveness of these antibiotics

## FOODS

*coffee; eggs; foods that contain bicarbonates, carbonates, oxalates, or phosphates; milk and milk products; tea that contains tannic acid; whole-grain breads and cereals and other high-fiber foods*: Decreased iron absorption and effectiveness

## ACTIVITIES

*alcohol abuse (acute or chronic)*: Increased serum iron level

## Adverse Reactions

**CNS**: Dizziness, fever, headache, paresthesia, syncope

**CV**: Chest pain, hypertension, **hypotension**, tachycardia

**EENT**: Metallic taste, tooth discoloration

**GI:** Abdominal cramps, constipation, epigastric pain, nausea, stool discoloration, vomiting

**HEME:** Hemochromatosis, **hemolysis**, hemosiderosis

**RESP:** Dyspnea, wheezing

**SKIN:** Diaphoresis, flushing, pruritus, rash, urticaria

**Other:** **Anaphylaxis** (with I.V. administration), **angioedema**, injection-site discoloration

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Give iron tablets and capsules with a full glass of juice or water. Don't crush enteric-coated tablets or open capsules.
- Dilute and administer with a straw or place drops in back of patient's throat, because iron solutions may stain teeth. Mix the elixir form in water. Fer-In-Sol Drops or Syrup may be mixed with juice or water.
- Know that to maximize absorption, iron salts should be given 1 hour before or 2 hours after meals. If GI irritation occurs, give with or just after meals.
- Protect liquid form from freezing.

- Administer Injectafer intravenously, either as an undiluted slow I.V. push or by infusion. When administering as a slow I.V. push, give at the rate of about 100 mg (2 ml) per minute. When administering via infusion, dilute up to 750 mg of iron in no more than 250 ml of sterile 0.9% sodium chloride injection, USP, such that the concentration of the infusion is not less than 2 mg of iron per ml, and administer over at least 15 minutes. Once diluted, solution is stable for 72 hours at room temperature.
- Avoid extravasation with I.V. administration because brown discoloration of the extravasation site may be long-lasting.

**WARNING** Monitor patients closely for hypersensitivity reactions for at least 30 minutes after I.V. administration. If present, discontinue drug immediately, notify prescriber, and be prepared to provide supportive care, as needed.

- Monitor patient's blood pressure after each I.V. dose for significant increases, as hypertension may occur immediately after administration but usually resolves within 30 minutes.
- Be aware that at usual dosages, serum hemoglobin level usually normalizes in about 2 months unless blood loss continues. Treatment may last for 3 to 6 months to help replenish iron stores.

**WARNING** Monitor patient for signs of iron overdose, which may include abdominal pain, diarrhea (possibly bloody), nausea, severe vomiting, and sharp abdominal cramps. In case of iron toxicity or accidental iron overdose (a leading cause of fatal poisoning in children under age 6), give deferoxamine, as prescribed. As few as 3 adult iron tablets can cause serious poisoning in young children.

- Don't give antacids, coffee, dairy products, eggs, tea, or whole-grain breads or cereals within 1 hour before or 2 hours after iron.
- Remember that unabsorbed iron turns stool black or green and can mask blood in stool. Check stool for occult blood, as ordered.

## **PATIENT TEACHING**

- Instruct patient not to chew any solid form of iron except for chewable tablets.
- Caution patient receiving Injectafer to immediately report any signs and symptoms of an allergic reaction such as hives, itching, wheezing, or feeling faint. Also alert patient that Injectafer may raise his blood pressure and to report dizziness, flushing, or nausea to prescriber.
- Urge patient to eat chicken, fish, lean red meat, and turkey, as well as foods rich in vitamin C (such as citrus fruits and fresh vegetables) to improve iron absorption.
- Urge patient to avoid foods that impair iron absorption, including dairy products, eggs, spinach, and high-fiber foods, such as whole-grain breads and cereals and bran. Also advise her to avoid drinking coffee or tea within 1 hour of iron intake.
- Caution patient not to take antacids or calcium supplements within 1 hour before and 2 hours after taking iron supplement.
- Inform patient that stool should become dark green or black during therapy. Advise her to notify prescriber if it doesn't.
- Tell patient to minimize tooth stains from liquid iron, by mixing dose with, fruit juice, tomato juice, or water and to drink it with a straw. If patient must take liquid iron by dropper, direct her to place drops well back on the tongue and to follow with water or juice. Tell her that iron stains can be removed by brushing with baking soda (sodium bicarbonate).
- Advise patient to consult prescriber before taking large amounts of iron for longer than 6 months.
- Warn patient about high risk of accidental poisoning, and urge her to keep iron preparations out of the reach of children.
- Tell mothers who are breastfeeding while receiving Injectafer to monitor their infant for gastrointestinal toxicity such as constipation and diarrhea.

## fesoterodine fumarate

### **Toviaz**

# Class and Category

*Pharmacologic class:* Muscarinic receptor antagonist

*Therapeutic class:* Antispasmodic

# Indications and Dosages

- *To treat overactive bladder with symptoms of urinary frequency, incontinence, and urgency*

## E.R. TABLETS

**Adults.** *Initial:* 4 mg daily, increased to 8 mg, as needed.

*Maximum:* 8 mg daily.

***DOSAGE ADJUSTMENT*** For patients with severe renal insufficiency (creatinine clearance less than 30 ml/min) or who are taking potent CYP3A4 inhibitors (such as clarithromycin, itraconazole, and ketoconazole), dosage shouldn't exceed 4 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	5 hr	Unknown

# Mechanism of Action

Exerts antimuscarinic (atropine-like) and potent direct antispasmodic (papaverine-like) actions on smooth muscle in the bladder. The result is increased bladder capacity and a decreased urge to void. Fesoterodine has an active metabolite that inhibits bladder contraction and decreases detrusor pressure.

# Contraindications

Gastric retention; hypersensitivity to fesoterodine, tolterodine tartrate extended-release capsules or immediate-release tablets, or their components; uncontrolled narrow-angle glaucoma; urine retention

## Interactions

### DRUGS

*antimuscarinic agents*: Possibly increased anticholinergic effects; possibly altered absorption of oral drugs taken concurrently

*potent CYP3A4 inhibitors, such as clarithromycin, itraconazole, ketoconazole*: Possibly increased serum fesoterodine level and increased risk of adverse effects

### FOODS

*caffeine*: May aggravate bladder symptoms

### ACTIVITIES

*alcohol use*: Increased drowsiness

## Adverse Reactions

**CNS**: Dizziness, drowsiness, headache, insomnia, somnolence

**CV**: Angina, chest pain, palpitations, peripheral edema, **QT-interval prolongation**

**EENT**: Blurred vision; dry eyes, mouth, or throat

**GI**: Constipation, diverticulitis, dyspepsia, elevated liver enzymes, gastroenteritis, irritable bowel syndrome, nausea, upper abdominal pain

**GU:** Dysuria, urine retention, UTI

**MS:** Back pain

**RESP:** Cough, upper respiratory tract infection

**SKIN:** Decreased sweating, pruritus, rash, urticaria

**Other:** **Angioedema**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cautiously in patients with significant bladder outlet obstruction because fesoterodine can cause urine retention.
- Use cautiously in patients with controlled narrow-angle glaucoma, decreased GI motility, or myasthenia gravis because drug can make these conditions worse.
- Use cautiously in patients taking other drugs with anticholinergic effects, such as antihistamines.
- Monitor patient closely for angioedema, which may occur after the first dose. If present, discontinue fesoterodine therapy immediately, as ordered, and provide emergency supportive care, including maintaining a patent airway, as needed.

- Monitor patient for CNS anticholinergic effects, especially after beginning fesoterodine therapy or increasing the dose. If present, notify prescriber, as dosage may need to be reduced or drug discontinued.

## PATIENT TEACHING

- Instruct patient to take drug exactly as prescribed.
- Tell patient to take drug with a full glass of water and not to cut, crush, or chew tablets.
- Explain that drug can cause adverse effects such as constipation and urine retention. If they occur and are severe or prolonged, patient should notify prescriber.
- Tell patient to seek immediate emergency medical attention if he experiences difficulty breathing or any swelling of his face, lips, throat, or tongue.
- Advise patient to avoid alcohol consumption during fesoterodine therapy.
- Tell patient to avoid hazardous activities until drug's CNS effects are known.
- Caution patient to avoid strenuous exercise and excessive sun exposure because of increased risk of heatstroke.
- Advise patient to limit caffeine consumption during drug therapy.
- Explain that full benefits of fesoterodine therapy may take 2 to 3 months.
- Inform patient that chewing sugarless gum or sucking hard candy (especially lemon drops) may help ease dry mouth.

**fidaxomicin**

**Dificid**

## Class and Category

*Pharmacologic class:* Macrolide  
*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat Clostridium difficile-associated diarrhea (CDAD)*

### **TABLET**

**Adults.** 200 mg twice daily for 10 days.

## Mechanism of Action

Inhibits RNA synthesis in *Clostridium difficile* bacterial cells by RNA polymerases, causing the cells to die.

## Contraindications

Hypersensitivity to fidaxomicin or its components

## Interactions

### **DRUGS**

*cyclosporine:* Possible increased blood fidaxomicin level

## Adverse Reactions

**ENDO:** Hyperglycemia

**GI:** Abdominal distention or pain, dyspepsia, dysphagia, elevated liver enzymes, flatulence, **GI hemorrhage**, **intestinal obstruction**, **megacolon**, nausea, vomiting

**HEME:** Anemia, **neutropenia**, **thrombocytopenia**

**RESP:** Dyspnea

**SKIN:** Drug eruption, pruritus, rash

**Other:** **Angioedema**, **decreased blood bicarbonate**, elevated blood alkaline phosphatase, **metabolic acidosis**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that fidaxomicin should only be used to treat infections that are caused or strongly suspected to be caused by *Clostridium difficile*.
- Know that fidaxomicin and other drugs for *C. difficile*-associated diarrhea are most effective when patients are not taking other antibiotics. If other antibiotics can be stopped safely, expect them to be withheld during the 10 days of fidaxomicin therapy.
- Monitor patient for hypersensitivity reactions that may include angioedema, dyspnea, pruritus, or rash. Patients with a history of allergy to other macrolides are at increased risk. If a severe reaction occurs, discontinue fidaxomicin immediately and notify prescriber. Provide supportive care, as needed and ordered.
- Monitor patient for adverse effects and notify prescriber, if present.

### PATIENT TEACHING

- Instruct patient to take fidaxomicin exactly as prescribed and for the full 10 days, regardless of how he is feeling.
- Tell patient to seek immediate emergency care if an allergic reaction occurs during fidaxomicin therapy.
- Tell patient to notify prescriber if symptoms worsen at any time or don't improve after a few days.

## **filgrastim**

**(granulocyte colony-stimulating factor, rG-CSF)**

**Grastofil (CAN), Neupogen**

## **filgrastim-aafi**

**Nivestym**

## **filgrastim-sndz**

**(granulocyte colony-stimulating factor, G-CSE)**

**Zarxio**

## **tbo-filgrastim**

**Granix**

# Class and Category

*Pharmacologic class:* Colony-stimulating factor

*Therapeutic class:* Hematopoietic

## Indications and Dosages

- *To reduce infection in patients with nonmyeloid malignancies after myelosuppressive chemotherapy associated with a significant incidence of severe neutropenia with fever; to reduce neutrophil recovery time and duration of fever following induction or consolidation chemotherapy in patients with acute myeloid leukemia*

### **I.V. INFUSION (GRASTOFIL, NEUPOGEN, NIVESTYM, ZARXIO)**

**Adults and children.** *Initial:* 5 mcg/kg daily over 15 to 30 min by short intravenous infusion or as continuous infusion infused over 24 hr given daily for up to 2 wk or until absolute neutrophil count (ANC) has reached  $10,000/\text{mm}^3$  following the expected chemotherapy-induced neutrophil nadir beginning 24 hr or more after cytotoxic chemotherapy. Increased, as needed, by 5 mcg/kg with each chemotherapy cycle.

### **SUBCUTANEOUS INJECTION (GRASTOFIL, NEUPOGEN, NIVESTYM, ZARXIO)**

**Adults and children.** *Initial:* 5 mcg/kg daily for up to 2 wk or until ANC has reached  $10,000/\text{mm}^3$  following the expected chemotherapy-induced neutrophil nadir beginning 24 hr or more after cytotoxic chemotherapy. Increased, as needed, by 5 mcg/kg with each chemotherapy cycle.

- *To reduce the duration of severe neutropenia in patients with nonmyeloid malignancies after receiving myelosuppressive chemotherapy associated with a significant incidence of febril neutropenia*

## **SUBCUTANEOUS INJECTION (GRANIX)**

**Adults and children age 1 month and older.** 5 mcg/kg daily starting no earlier than 24 hr after myelosuppressive chemotherapy and continued until the neutrophil count has recovered to normal.

- *To reduce duration of neutropenia in patients with nonmyeloid malignancies undergoing myeloablative chemotherapy followed by bone marrow transplantation*

## **I.V. INFUSION (GRASTOFIL, NEUPOGEN, NIVESTYM, ZARXIO)**

**Adults. Initial:** 10 mcg/kg daily as a continuous infusion for no longer than 24 hr beginning at least 24 hr after bone marrow infusion and cytotoxic chemotherapy. Dosage adjusted according to ANC response.

- *To mobilize autologous hematopoietic progenitor cells into the peripheral blood for collection by leukapheresis*

## **SUBCUTANEOUS INJECTION (GRASTOFIL, NEUPOGEN, NIVESTYM, ZARXIO)**

**Adults.** 10 mcg/kg daily starting at least 4 days before first leukapheresis and continuing until last day of leukapheresis.

- *To reduce occurrence and duration of severe neutropenia in congenital neutropenia*

## SUBCUTANEOUS INJECTION (GRASTOFIL, NEUPOGEN, NIVESTYM, ZARXIO)

**Adults and children.** *Initial:* 6 mcg/kg twice daily. Dosage adjusted, as needed.

- *To reduce the occurrence and duration of severe neutropenia in idiopathic or cyclic neutropenia*

## SUBCUTANEOUS INJECTION (GRASTOFIL, NEUPOGEN, ZARXIO)

**Adults and children.** *Initial:* 5 mcg/kg daily. Dosage adjusted as needed.

- *To treat patients acutely exposed to myelosuppressive doses of radiation*

## SUBCUTANEOUS INJECTION (NEUPOGEN)

**Adults.** 10 mcg/kg daily beginning as soon as possible after exposure to radiation doses greater than 2 gray and continued until ANC remains greater than 1,000/mm<sup>3</sup> for 3 consecutive CBCs or exceeds 10,000/mm<sup>3</sup> after a radiation-induced nadir.

- *To prevent and treat neutropenia in patients with HIV infection*

## SUBCUTANEOUS INJECTION (GRASTOFIL)

**Adults.***Initial:* 1 mcg/kg/day or 300 mcg three times weekly and continued with dosage adjustment, as needed, until a normal neutrophil count is reached and ANC is maintained at or greater than  $2 \times 10^9$ /L.

***DOSAGE ADJUSTMENT*** Dosage adjusted according to CBC with differential and platelet count response.

---

Route	Onset	Peak	Duration
-------	-------	------	----------

Route	Onset	Peak	Duration
I.V.	In 5 min	Unknown	Unknown

## Mechanism of Action

Is pharmacologically identical to human granulocyte colony-stimulating factor, an endogenous hormone synthesized by endothelial cells, fibroblasts and monocytes. Filgrastim induces formation of neutrophil progenitor cells by binding directly to receptors on the surface of granulocytes, which then divide and differentiate. It also potentiates the effects of mature neutrophils, which reduces fever and the risk of infection raised by severe neutropenia.

## Incompatibilities

Don't mix filgrastim with normal saline solution because precipitate will form.

## Contraindications

Hypersensitivity to filgrastim, other human granulocyte colony-stimulating factors such as pegfilgrastim, or their components

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Fever, headache

**CV:** Aortitis, transient **supraventricular tachycardia**

**GI:** **Splenic rupture**, splenomegaly

**GU:** Glomerulonephritis

**HEME:** Leukocytosis, **thrombocytopenia**

**MS:** Arthralgia; decreased bone density (children with chronic treatment); myalgia; pain in arms, legs, lower back, or pelvis: osteoporosis (children with chronic therapy)

**RESP:** **Acute respiratory distress syndrome (ARDS)**, **alveolar hemorrhage**, dyspnea, **hemoptysis**, wheezing

**SKIN:** Cutaneous vasculitis, pruritus, rash, Sweet's syndrome (acute febrile neutrophilic dermatosis)

**Other:** **Anaphylaxis**, **angioedema**, injection-site pain and redness, sickle cell crisis

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Warm filgrastim to room temperature before injection. Discard drug if stored longer than 6 hours at room temperature or 24 hours in refrigerator.
- Withdraw only one dose from a vial; don't repuncture the vial.
- Don't shake the solution.
- For continuous infusion, dilute in D<sub>5</sub>W (not normal saline solution) to produce less than 15 mcg/ml.
- For subcutaneous dose larger than 1 ml, divide and give in more than one site.
- For short I.V. infusion, give drug over 15 to 30 minutes.
- Don't give within 24 hours before or after cytotoxic chemotherapy.
- Be aware that needle cover on single-use prefilled syringe contains dry natural rubber (except for the brands Granix and Nivestym) and may cause sensitivity reaction. It shouldn't be handled by allergic people.
- Be aware that the brand Granix's prefilled syringe has a safety needle guard device for use by healthcare professionals only. To safely use the device, hold the syringe assembly by the open sides of the device and remove the needle shield. Expel any extra volume depending on dose needed. Inject Granix subcutaneously by pushing the plunger as far as it will go to inject all of the drug. Injection of the entire prefilled syringe contents is needed to activate the needle guard. With the plunger still pressed all the way down, remove the needle from the skin. Slowly let go of the plunger and allow the empty syringe to move up inside the device until the entire needle is guarded. Discard the syringe assembly in an approved container.
- Know that the Nivestym prefilled syringe with BD UltraSafe Plus Passive Needle Guard cannot be used for doses less than 0.3 ml (180 mcg), because the spring-mechanism of the needle guard apparatus affixed to the prefilled syringe interferes with the visibility of the graduation markings on the syringe barrel corresponding to 0.1 ml and 0.2 ml. For direct administration of doses less than 0.3 ml, the single-dose vial should be used instead to ensure accuracy.
- Expect to monitor CBC, hematocrit, and platelet count 2 or 3 times weekly.
- Inform prescriber and expect to stop drug if leukocytosis develops or absolute neutrophil count consistently exceeds 10,000/mm<sup>3</sup>.
- Anticipate decreased response to drug if patient has received extensive radiation therapy or long-term chemotherapy.

- Know that aortitis has occurred in patients receiving filgrastim, occurring as early as the first week after start of therapy. Monitor patient for generalized signs and symptoms such as abdominal pain, back pain, fever, and malaise. Increased inflammatory markers (e.g., C-reactive protein and white blood cell count) help to confirm the diagnosis. Expect drug to be discontinued if aortitis is suspected.
- Monitor patient's renal function, as ordered, because drug may cause glomerulonephritis. If abnormalities occur, expect dosage to be reduced or drug discontinued.

**WARNING** Monitor patients with sickle cell anemia receiving filgrastim, as sickle cell crisis can occur that can be life-threatening. Notify prescriber immediately if sickle cell crisis occurs. Expect drug to be discontinued.

## PATIENT TEACHING

- Review possible serious side effects (allergic reactions, capillary leak syndrome, hematological abnormalities, inflammation of blood vessels, kidney injury, respiratory distress syndrome, and sickle cell crises) with patient before drug is given and determine patient's understanding. Tell her the most common side effect is aching in the bones and muscles.
- Teach patient how to prepare, administer, and store drug. Caution her not to reuse needle, syringe, or vial.
- Alert patient that there is a difference in drug concentration between the prefilled syringe and vial of the brand Neuprogen. Tell patient to make sure she is administering the correct volume of Neuprogen for the dose prescribed.
- Advise patient prescribed single-use prefilled syringe to notify prescriber if she has an allergy to latex, unless she is using the brands Granix or Nivestym, because needle cover may cause sensitivity reaction.
- Provide patient with puncture-resistant container for needle and syringe disposal.
- Instruct patient who is self-injecting drug to notify prescriber if a dose is missed, to obtain instructions on when to take the next dose.
- Advise patient to promptly report pain in left upper quadrant of abdomen or shoulder-tip pain. Also tell patient to report any persistent, severe, or unusual signs and symptoms to prescriber and seek emergency medical

attention, if needed. For example, tell her that difficulty breathing, facial swelling, rash, or wheezing require immediate attention.

- Emphasize the importance of returning for follow-up laboratory tests.
- Advise female patient to report pregnancy to prescriber immediately and encourage her to enroll in Amgen's Pregnancy Surveillance Program by calling 1-800-77-AMGEN.
- Instruct patient to inform all prescribers of filgrastim or filgrastim-sndz use. Patient should not take any over-the-counter preparations until after speaking to prescriber.

## finasteride

### Propecia, Proscar

## Class and Category

*Pharmacologic class:* 5-alpha reductase inhibitor

*Therapeutic class:* Benign prostatic hyperplasia agent, hair growth stimulant

## Indications and Dosages

- *To treat symptomatic benign prostatic hyperplasia; to reduce the risk of symptomatic progression of benign prostatic hyperplasia when given with doxazocin*

### **TABLETS (PROSCAR)**

**Adults.** 5 mg daily.

- *To treat male-pattern baldness*

### **TABLETS (PROPECIA)**

**Adults.** 1 mg daily.

Route	Onset	Peak	Duration
P.O.*	Unknown	8 hr	24 hr <sup>†</sup>
P.O. <sup>‡</sup>	In 3 mo	Unknown	Unknown

\* For benign prostatic hyperplasia.

† With single-dose therapy; 2 wk with multiple-dose therapy.

‡ For male-pattern baldness.

## Mechanism of Action

Inhibits 5-alpha reductase, an intracellular enzyme that converts testosterone to its metabolite (5-alpha dihydrotestosterone) in liver, prostate, and skin. The metabolite is a potent androgen partially responsible for benign prostatic hyperplasia and hair loss.

## Contraindications

Females, hypersensitivity to finasteride or its components

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Asthenia, depression, dizziness, headache, **progressive multifocal leukoencephalopathy** (extremely rare)

**CV:** **Hypotension**, peripheral edema

**EENT:** Lip swelling, rhinitis

**ENDO:** Gynecomastia, **male breast cancer**

**GI:** Abdominal pain, diarrhea

**GU:** Altered prostate-specific antigen level, decreased ejaculatory volume, decreased libido, erectile dysfunction, **high-grade prostate cancer**, impotence, male infertility, testicular pain

**MS:** Back pain

**RESP:** Dyspnea

**SKIN:** Pruritus, rash, urticaria

**Other:** **Angioedema**

## **Childbearing Considerations**

### **PREGNANCY**

- Drug is known to cause fetal harm in the male fetus by preventing normal development of male genitalia.
- Drug is not indicated for use in women and is contraindicated in pregnant women and women of childbearing age.
- Women of childbearing age or who are pregnant should not handle crushed or broken tablets because of the possibility of absorption and subsequent potential risk to a male fetus.

### **LACTATION**

- It is not known if drug is present in breast milk.
- Drug is not indicated for use in women.

## **Nursing Considerations**

- Be aware that patient should have a urologic evaluation prior to starting finasteride therapy and periodically throughout therapy because drug can increase the risk of prostate cancer, especially high-grade prostate cancer.
- Expect patient to have a digital rectal examination of the prostate before and periodically during finasteride therapy.
- Be aware that finasteride therapy affects PSA levels. For example, drug may decrease levels even in the presence of prostate cancer. Any increases, no matter how slight or even if increase is still within normal limits, warrant further evaluation because of finasteride's risk of high-grade prostate cancer.
- Be aware that pregnant female healthcare workers should not handle broken finasteride tablets because of potential adverse effect on male fetus.

## PATIENT TEACHING

**WARNING** Urge patient and female partners to use reliable contraception during therapy because semen of men who take drug can harm male fetuses. Caution women and children not to handle broken tablets.

- Explain how to take drug, and urge patient to follow instructions that accompany it.
- Inform patient that drug may cause a variety of sexual dysfunction problems including decreased libido, erectile dysfunction, and male infertility, which may continue after drug is discontinued.
- Urge patient to have periodic follow-up to determine drug effectiveness.
- Caution patient that noncompliance with therapy may affect PSA test results.

# fingolimod hydrochloride

## Gilenya

## Class and Category

*Pharmacologic class:* Sphingosine 1-phosphate receptor modulator

*Therapeutic class:* Antimultiple sclerotic

## Indications and Dosages

- *To treat relapsing forms of multiple sclerosis (MS), including active secondary progressive disease, clinically isolated syndrome, and relapsing-remitting disease*

### CAPSULES

**Adults and children age 10 and over weighing more than 40 kg (88 lb).** 0.5 mg once daily.

**Children age 10 and over weighing 40 kg (88 lb) or less.** 0.25 mg once daily.

## Mechanism of Action

Possibly involves reduction of lymphocyte migration into the central nervous system to produce improved physical mobility.

## Contraindications

Baseline QTc interval equal to or greater than 500 msec; experience within past 6 months of class III or IV heart failure, decompensated heart failure requiring hospitalization, MI, stroke, TIA, or unstable angina; history or presence of Mobitz Type II second-degree or third-degree atrioventricular block or sick sinus syndrome unless patient has functioning pacemaker in place;

hypersensitivity to fingolimod or its components; presence of arrhythmias requiring the use of Class Ia or Class III antiarrhythmic drugs

## Interactions

### DRUGS

*antineoplastics, immunosuppressives, immunomodulators:*

Increased immunosuppression

*beta blockers, calcium channel blockers such as diltiazem*

*or verapamil, digoxin:* Possibly increased severity of bradycardia or slowing of atrioventricular conduction

*chlorpromazine, citalopram, erythromycin, haloperidol,*

*methadone:* Possibly increased risk for prolonged QT interval which may lead to torsades de pointes

*ketoconazole:* Increased fingolimod levels

*live attenuated vaccines:* Increased risk of contracting disease from live virus

*vaccines:* Decreased effectiveness of vaccines during and up to 2 months after fingolimod therapy

## Adverse Reactions

**CNS:** Asthenia, depression, dizziness, headache, migraine, paresthesia, **posterior reversible encephalopathy**

**syndrome, progressive multifocal leukoencephalopathy, seizures, status epilepticus,** syncope, tumefactive demyelinating lesions

**CV:** **Atrioventricular blocks, bradycardia,** elevated blood triglycerides, hypertension, **transient asystole**

**EENT:** Blurred vision, eye pain, macular edema, sinusitis

**GI:** Diarrhea, elevated liver enzymes, gastroenteritis, **liver injury**

**HEME:** Hemolytic anemia, leukopenia, lymphopenia, thrombocytopenia

**MS:** Arthralgia, back pain, myalgia, severe increase in disability with discontinuation of therapy

**RESP:** Bronchitis, cough, dyspnea, pulmonary dysfunction

**SKIN:** Alopecia, basal cell carcinoma, eczema, melanoma, Merkel cell carcinoma, pruritus, rash, squamous cell carcinoma, tinea infections, urticaria

**Other:** Angioedema; flu-like symptoms; increased severity of herpes viral infections, including human papilloma viral infections; infections such as bacterial, fungi, and viral; lymphomas; weight loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-877-598-7237, email: [gpr@quintiles.com](mailto:gpr@quintiles.com), or website: [www.gilenyapregnancyregistry.com](http://www.gilenyapregnancyregistry.com).
- Pregnancy status of women of childbearing age should be determined before drug therapy is started.
- Drug may cause fetal harm. Animal studies suggest an increase risk of developmental toxicity.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### REPRODUCTION

- Women of childbearing age should use effective contraception during drug therapy and for 2 months after drug is discontinued.
- Women who plan to become pregnant need to have drug discontinued 2 months before planned conception.

## Nursing Considerations

- Be aware that fingolimod therapy should not begin in a patient with an active acute or chronic infection until the infection is resolved, because drug causes a dose-dependent reduction in peripheral lymphocyte count up to 30% of baseline values.
- Immunize patient against the varicella zoster virus if he is antibody negative, as ordered. Be aware that fingolimod therapy will need to be postponed for 1 month to allow the full effect of vaccination to occur.
- Expect patient to be vaccinated against human papilloma virus (HPV) prior to fingolimod therapy taking into account vaccination recommendations because infections caused by HPV have occurred during drug therapy. Cancer screening, including Papanicolaou test should be done routinely.
- Obtain an electrocardiogram on patients receiving antiarrhythmic therapy including beta-blockers and calcium channel blockers, those with cardiac risk factors, and those who have an irregular or slow heartbeat prior to beginning fingolimod therapy because drug may cause bradycardia and increased risk for atrioventricular block, especially in the first 24 hours of therapy.
- Obtain a recent complete blood count (within past 6 months) prior to starting therapy, as ordered, because drug increases risk of infection, especially bacterial, fungi, and viral, that may become serious and life-threatening. Monitor patient throughout drug therapy for signs and symptoms of infection. If present, notify prescriber, and expect drug to be discontinued if serious and infection treated according to standard of care.
- Expect patient to have an ophthalmologic evaluation prior to beginning drug therapy and then again 3 to 4 months after therapy has begun to assess for macular edema. Patients with diabetes mellitus or a history of uveitis should have ongoing evaluations because they are at increased risk for macular edema. Report any visual disturbances to prescriber during drug therapy and expect additional ophthalmologic evaluation to be performed, if present, and drug discontinued. Visual acuity loss may persist even after resolution of macular edema in some patients.

- Obtain a recent liver enzyme evaluation (within past 6 months) prior to initiating fingolimod therapy, as ordered, because drug may cause elevation of liver enzymes. Monitor periodically throughout therapy and expect drug to be discontinued if liver enzymes exceed 5 times the upper limit of normal. Also evaluate in patient who develops symptoms suggestive of hepatic dysfunction, such as unexplained abdominal pain, anorexia, dark urine, fatigue, jaundice, nausea, and vomiting. Know that patients with preexisting liver disease may be at increased risk for developing elevated liver enzymes during fingolimod therapy.
- Monitor patient for hypersensitivity reactions such as angioedema, rash, or urticaria following administration. Prepare to provide supportive care if present and expect drug to be discontinued.
- Observe patient for 24 hours after the first dose of fingolimod for signs and symptoms of bradycardia. Heart rate usually begins to decrease within an hour of the first dose. The maximal decline in heart rate usually occurs within 6 hours and recovers but not to baseline level within 10 hours after the first dose. A second decline may occur after the first within the first 24 hours after the first dose. Monitor patient closely because the second decline may be more pronounced than the first. If patient develops chest pain, dizziness, fatigue, hypotension, or palpitations, notify prescriber, initiate appropriate management, as ordered, and continue observation until the symptoms have resolved. Know that with continued drug use, the heart rate returns to baseline within one month. Also observe patient closely for cardiac effects after drug is reinitiated if treatment is discontinued or interrupted for certain periods, as well as after dosage increases.
- Monitor patient for dyspnea throughout fingolimod therapy because drug may reduce diffusion lung capacity for carbon monoxide (DLCO) and forced expiratory volume over 1 second. Expect to perform spirometric evaluations of respiratory function and evaluation of DLCO during therapy, if clinically indicated.
- Monitor patient's blood pressure regularly to detect development of hypertension.
- Assess patient's skin for abnormalities, as drug may increase risk of basal cell carcinoma, melanoma, and Merkel cell carcinoma. Promptly report any suspicious looking lesions.
- Be aware that tumefactive demyelinating lesions may occur within the first 9 months after fingolimod has begun and may also occur within 4 months after drug is discontinued. Expect prompt imaging evaluation and initiation of appropriate treatment in patients who develop a severe multiple sclerosis relapse during fingolimod therapy.

- Be aware that it takes about 2 months for drug effects to be gone after therapy is discontinued requiring patient to be monitored for adverse effects during this time. Also be aware that severe increase in disability may occur after discontinuation of drug, which may occur up to 24 weeks after drug is stopped. Assess patient's level of function during this time and expect appropriate treatment to be given, as needed.

## **PATIENT TEACHING**

- Inform patient that he will need to be observed for at least 6 hours after the first dose. He will need to repeat this observation period again for 6 hours if treatment is interrupted for more than 1 day within the first 2 weeks of therapy, if treatment is interrupted for more than 7 days during week 3 and 4 of therapy, or if treatment is discontinued for more than 14 days and then treatment is reinitiated, as well as any time dosage is increased.
  - Tell patient to report any adverse signs and symptoms of infection or any other persistent or serious abnormalities to prescriber promptly, even up to 2 months after drug has been discontinued.
  - Advise patient to examine his skin regularly for skin abnormalities, because drug may increase risk of skin cancer, including melanoma. Tell patient to report any suspicious skin lesion to prescriber for evaluation. Remind patient to limit exposure to sunlight and ultraviolet light and to wear protective clothing and use a sunscreen with a high protection factor when going outdoors.
  - Instruct female patients to use effective contraception to avoid pregnancy during and for 2 months after fingolimod therapy is discontinued because of potential fetal harm. Stress importance of notifying prescriber immediately if pregnancy is suspected or occurs.
  - Instruct patient how to check his pulse and tell him to notify prescriber if his pulse rate drops below 60 beats per minute or becomes irregular.
  - Advise patient to notify prescriber immediately if difficulty breathing or visual changes occurs.
  - Tell patient to notify prescriber if he notices symptoms suggestive of liver dysfunction, such as unexplained abdominal pain, anorexia, dark urine, fatigue, jaundice, nausea, or vomiting.
  - Alert patient of the need to have periodic blood work done during fingolimod therapy and urge him to be compliant with these evaluations.
-

# flavoxate hydrochloride

**Urispas**

## Class and Category

*Pharmacologic class:* Flavone derivative

*Therapeutic class:* Urinary tract antispasmodic

## Indications and Dosages

- *To relieve dysuria; nocturia; suprapubic pain; urinary frequency, incontinence, and urgency caused by cystitis, prostatitis, urethritis, urethrocystitis, or urethrotrigonitis*

## TABLETS

**Adults and adolescents.** 100 to 200 mg 3 times daily or 4 times daily. Dosage reduced with improvement.

Route	Onset	Peak	Duration
P.O.	55 min	112 min	Unknown

## Mechanism of Action

Relaxes muscles by cholinergic blockade and counteracts smooth-muscle spasms in the urinary tract.

## Contraindications

Achalasia; duodenal or pyloric obstruction; GI hemorrhage; hypersensitivity to flavoxate or its components; obstructive intestinal lesions or ileus; obstructive uropathies of the lower urinary tract

## Interactions

### DRUGS

*bethanechol, metoclopramide*: Possibly antagonized GI motility effects of these drugs

## Adverse Reactions

**CNS:** Confusion, decreased concentration, dizziness, drowsiness, fever, headache, nervousness, vertigo

**CV:** Palpitations, tachycardia

**EENT:** Accommodation disturbances, blurred vision, dry mouth, eye pain, photophobia, worsening of glaucoma

**GI:** Constipation, nausea, vomiting

**GU:** Dysuria

**HEME:** Eosinophilia, **leukopenia**

**SKIN:** Decreased sweating, dermatoses, urticaria

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Monitor for eye pain if patient has glaucoma because flavoxate's anticholinergic effects may worsen glaucoma.

## PATIENT TEACHING

- Caution patient about possible dry mouth and photophobia. Advise her to wear sunglasses outdoors, and suggest sugarless candy or gum, ice chips, saliva substitute, or sips of water for dry mouth.
- Advise patient to avoid hazardous activities until CNS effects of flavoxate are known.
- Caution patient not to become overheated or to take hot baths or saunas during therapy because drug reduces sweating, which can lead to dizziness, fainting, or heatstroke.
- Instruct patient to notify prescriber immediately if she experiences confusion, drowsiness, dysuria, headache, high fever, hives, nausea, nervousness, palpitations, rash, tachycardia, vertigo, vision problems, vomiting, or worsening dry mouth.

**flecainide acetate**

**Tambocor**

## Class and Category

*Pharmacologic class:* Benzamide derivative

*Therapeutic class:* Class IC antiarrhythmic

## Indications and Dosages

- *To prevent and suppress recurrent life-threatening ventricular tachycardia*

### **TABLETS**

**Adults.** *Initial:* 100 mg every 12 hr. Increased by 50 mg twice daily every 4 days, as needed, until response occurs. *Maintenance:* Up to 150 mg every 12 hr. *Maximum:* 400 mg daily.

- *To prevent paroxysmal atrial fibrillation or flutter or paroxysmal supraventricular tachycardia associated with disabling symptoms*

### **TABLETS**

**Adults.** *Initial:* 50 mg every 12 hr. Increased by 50 mg twice daily every 4 days, as needed, until response occurs. *Maintenance:* Up to 150 mg every 12 hr. *Maximum:* 300 mg daily.

***DOSAGE ADJUSTMENT*** Initial dose reduced to 100 mg daily or 50 mg every 12 hr for patients with creatinine clearance less than 35 ml/min.

## Mechanism of Action

Achieves antiarrhythmic effect by inhibiting fast sodium channels of myocardial cell membranes, which increase myocardial recovery after repolarization, and by depressing the upstroke of the action potential. Flecainide also produces its antiarrhythmic effect by:

- slowing intracardiac conduction, which slightly increases the duration of the action potential in atrial and ventricular muscle, thus prolonging the PR interval, QRS complex, and QT interval
- shortening the action potential of Purkinje fibers without affecting surrounding myocardial tissue
- inhibiting extracellular calcium influx (at high doses)
- stopping paroxysmal reentrant supraventricular tachycardias by acting on antegrade pathways of dysfunctional AV conduction
- decreasing conduction in accessory pathways in those with Wolff-Parkinson-White syndrome.

## Contraindications

Cardiogenic shock, hypersensitivity to flecainide or its components, recent MI, right bundle-branch block associated with left hemiblock or second- or third-degree AV block unless pacemaker is present

## Interactions

### DRUGS

*amiodarone*: Increased blood flecainide level

*antiretrovirals*: Possibly increased flecainide levels

*beta blockers such as propranolol*: Possibly myocardial depression and increased blood levels of both drugs

*digoxin*: Possibly increased blood digoxin level

*quinidine*: Possibly increased plasma flecainide concentrations in patients on chronic flecainide therapy, especially if these patients are extensive metabolizers

### FOODS

*acidic juices, foods that decrease urine pH below 5.0*: Increased flecainide elimination and decreased therapeutic effects

*foods that increase urine pH above 7.0, strict vegetarian diet:* Decreased flecainide elimination and increased therapeutic effects

## **ACTIVITIES**

*smoking:* Increased flecainide clearance

## **Adverse Reactions**

**CNS:** Anxiety, depression, dizziness, drowsiness, fatigue, headache, light-headedness, tremor, weakness

**CV:** **Arrhythmias**, chest pain, **heart failure**, **hypotension**

**EENT:** Blurred vision

**GI:** Abdominal pain, anorexia, constipation, **hepatic dysfunction**, nausea, vomiting

**RESP:** Dyspnea

**SKIN:** Rash

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LACTATION**

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

# Nursing Considerations

- Monitor urine pH beginning at the start of flecainide therapy.
- Check blood pressure, fluid intake and output, and weight regularly during therapy.
- Monitor trough flecainide level, as needed; therapeutic level is 0.2 to 1 mcg/ml.
- Expect drug to cause mild to moderate negative inotropic effects, minimal cardiovascular effects, and no effect on blood pressure, heart rate, and left ventricular function.

**WARNING** Know that because hypokalemia or hyperkalemia may interfere with flecainide's therapeutic effects, serum potassium level must be monitored before and during therapy as ordered, and notify prescriber immediately if potassium imbalance develops. Also monitor for and notify prescriber about prolonged PR interval, QRS complex, or QT interval; chest pain; hypotension; and signs of heart failure. Keep in mind that drug can cause fatal proarrhythmias, which is why it isn't considered a first-line antiarrhythmic.

- Expect prolonged flecainide therapy to raise blood alkaline phosphatase level.

## PATIENT TEACHING

- Instruct patient to take flecainide at regular intervals to keep a constant blood level.
- Advise patient to take a missed dose as soon as she remembers if it's within 6 hours of the scheduled time.
- Teach patient how to take her pulse, and instruct her to record it daily, along with her weight. Advise her to bring record to follow-up visits.
- Encourage family members to obtain instruction in basic cardiac life support.

- Advise patient to notify prescriber immediately about chest pain, difficulty breathing, and dizziness.
- Caution patient not to stop taking flecainide suddenly but to taper dosage gradually according to prescriber's instructions.

# fluconazole

## Diflucan

### Class and Category

*Pharmacologic class:* Azole antifungal

*Therapeutic class:* Antifungal

### Indications and Dosages

➤ *To treat oral and esophageal candidiasis*

#### ORAL SUSPENSION, TABLETS, I.V. INFUSION

**Adults and adolescents.** 200 mg on day 1 followed by 100 mg daily for at least 2 (oral) or 3 (esophageal) wk after symptoms resolve. I.V. dosage infused at a rate no greater than 200 mg/hr.

**Children.** 6 mg/kg on day 1, followed by 3 mg/kg daily for at least 2 (oral) or 3 (esophageal) wk and then for 2 wk after esophageal symptoms resolve. I.V. dosage infused at a rate no greater than 200 mg/hr.

➤ *To treat systemic candidiasis*

#### ORAL SUSPENSION, TABLETS, I.V. INFUSION

**Adults and children.** Highly individualized. *Maximum:* 400 mg daily (adults) and 12 mg/kg/day (children). I.V. dosage infused at a rate no greater than 200 mg/hr.

➤ *To treat cryptococcal meningitis*

## **ORAL SUSPENSION, TABLETS, I.V. INFUSION**

**Adults and adolescents.** 400 mg on day 1, followed by 200 to 400 mg daily based on patient's response, and continued for 10 to 12 wk after CSF culture is negative. *Maintenance:* 200 mg daily to suppress relapse. I.V. dosage infused at a rate no greater than 200 mg/hr.

**Children.** 12 mg/kg on day 1, followed by 6 to 12 mg/kg daily and continued for 10 to 12 wk after CSF culture is negative. I.V. dosage infused at a rate no greater than 200 mg/hr.

➤ *To prevent candidiasis after bone marrow transplantation in patients who receive cytotoxic chemotherapy and/or radiation*

## **ORAL SUSPENSION, TABLETS, I.V. INFUSION**

**Adults and adolescents.** 400 mg daily starting several days before procedure if severe neutropenia is expected and continued for 7 days after absolute neutrophil count exceeds 1,000/mm<sup>3</sup>. I.V. dosage infused at a rate no greater than 200 mg/hr.

➤ *To treat vaginal candidiasis*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 150 mg as a single dose.

***DOSAGE ADJUSTMENT*** After initial loading dose, dosage reduced for all indications by 50% for patients with creatinine clearance of 11 to 50 ml/min. For patient on hemodialysis, usual dosage given after each hemodialysis;

on nondialysis days, dosage reduced according to the patient's creatinine clearance.

## **Mechanism of Action**

Damages fungal cells by interfering with a cytochrome P-450 enzyme needed to convert lanosterol to ergosterol, an essential part of the fungal cell membrane. Decreased ergosterol synthesis causes increased cell permeability, which allows cell contents to leak. Fluconazole also may inhibit endogenous respiration, interact with membrane phospholipids, inhibit transformation of yeasts to mycelial forms, inhibit purine uptake, and impair biosynthesis of triglycerides and phospholipids.

## **Incompatibilities**

Don't add fluconazole to I.V. container that contains any other drug.

## **Contraindications**

Coadministration of drugs known to prolong QT interval and which are metabolized via the enzyme CYP3A4 (astemizole, cisapride, erythromycin, pimozide, or quinidine) or concurrent therapy with terfenadine (when multiple dosages reach or exceed 400 mg), hypersensitivity to fluconazole or its components

## **Interactions**

### **DRUGS**

*alfentanil, amitriptyline, astemizole, celecoxib, cyclosporine, halofantrine, methadone, nortriptyline,*

*olaparib, phenytoin, rifabutin, saquinavir, sirolimus, theophylline, tofacitinib, trizolam, zidovudine*: Increased blood levels of these drugs with possible increase in adverse reactions

*amiodarone, astemizole, cisapride, erythromycin, pimozide, quinidine*: Increased risk of QT-interval prolongation possibly leading to torsades de pointes

*benzodiazepines (short-acting)*: Possibly increased benzodiazepine level and psychomotor effects

*calcium-channel blockers*: Possibly increased systemic exposure of calcium-channel blockers causing adverse effects

*carbamazepine*: Possibly increased risk of carbamazepine toxicity

*cyclophosphamide*: Increased serum bilirubin and creatinine levels

*fentanyl*: Possibly elevated fentanyl concentration that may lead to respiratory depression

*glipizide, glyburide, tolbutamide and other sulfonylurea*

*oral hypoglycemic agents*: Increased risk of hypoglycemia

*HMG-CoA reductase inhibitors*: Increased risk of myopathy and rhabdomyolysis

*hydrochlorothiazide*: Increased fluconazole level from decreased excretion

*losartan*: Possibly decreased hypotensive effect of losartan

*NSAIDs*: Increased systemic exposure of NSAIDs

*oral anticoagulants*: Increased anticoagulant effects

*prednisone*: Possibly increased risk of acute adrenal cortex insufficiency

*rifampin*: Decreased serum fluconazole level

*tacrolimus*: Increased tacrolimus levels, possibly leading to nephrotoxicity

*terfenadine*: Increased risk of serious cardiac arrhythmias; increased terfenadine levels when dosage of terfenadine is 400 mg/day or greater.

*vinca alkaloids*: Possibly increased plasma vinca alkaloids, which may lead to neurotoxicity

*vitamin A*: Possible adverse CNS effects

*voriconazole*: Increased risk of toxicity

## Adverse Reactions

**CNS:** Chills, dizziness, drowsiness, fever, headache, **seizures**

**CV:** **Prolonged QT interval, torsades de pointes**

**ENDO:** **Adrenal insufficiency**

**GI:** Abdominal pain, anorexia, constipation, diarrhea, **hepatic failure**, nausea, vomiting

**HEME:** **Agranulocytosis, leukopenia, thrombocytopenia**

**SKIN:** **Acute generalized exanthematous pustulosis**, alopecia, diaphoresis, drug eruption, **exfoliative dermatitis**, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**

**Other:** **Anaphylaxis, angioedema, drug reaction with eosinophilia and systemic symptoms (DRESS)**

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm such as distinct congenital anomalies in infants exposed in utero to high doses of the drug (400 to 800 mg per day) during most or all of the first trimester. Spontaneous abortions and congenital abnormalities may be potential risks even with 150 mg of the drug given as a single or repeated dose during the first trimester.
- Drug should be avoided in pregnancy except in patients with severe or potentially life-threatening fungal infections in whom the beneficial use of

the drug outweighs the potential risk to the fetus.

## **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **REPRODUCTION**

- Advise women of child bearing age to use effective contraceptive measures during drug therapy and for about 1 week after the final dose when prescribed 400 to 800 mg of the drug daily.

## **Nursing Considerations**

- Use fluconazole cautiously in patients with potentially proarrhythmic conditions because drug may prolong the QT interval, which can lead to life-threatening torsades de pointes.
- Expect to obtain BUN and serum creatinine levels, as well as culture, sensitivity, and liver enzymes, as ordered, before therapy starts.
- Refrigerate, but don't freeze, fluconazole oral suspension. Shake well before administering.
- Discard I.V. solution that's cloudy or contains precipitate. Don't infuse more than 200 mg/hr or add supplemental drugs to infusion.
- Monitor hepatic and renal function periodically during therapy, and notify prescriber if you detect signs of dysfunction.
- Assess for rash every 8 hours during therapy, and notify prescriber if rash occurs.
- Monitor coagulation test results and assess patient for bleeding if patient is receiving an oral anticoagulant.
- Monitor patient for symptoms of overdose, such as hallucinations and paranoia. If they occur, provide supportive treatment, gastric lavage, and, possibly, hemodialysis, which can reduce blood fluconazole level by half after about 3 hours.

## **PATIENT TEACHING**

- Instruct patient to take fluconazole tablets or oral suspension 30 minutes before or 2 hours after meals. Inform her that tablets may be crushed for easier swallowing if needed.
- Advise patient to complete entire course of therapy, even if she feels better.
- Tell patient to inform all prescribers of fluconazole use and not to take any over-the-counter preparations, including herbal preparations, without consulting prescriber first, as drug can interact with many other drugs and substances.
- Urge patient to monitor blood glucose level often if she takes an oral antidiabetic drug, because of increased risk of hypoglycemia.
- Alert patient that fluconazole may change the taste of food.
- Encourage patient to notify prescriber immediately about diarrhea, headache, nausea, rash, right-upper-quadrant abdominal pain, yellow skin or whites of eyes, or vomiting. Also tell patient to notify prescriber of fever, skin rash, swollen glands, or other persistent, severe, or unusual adverse reactions such as chronic fatigue, loss of appetite, muscle weakness, or weight loss.
- Urge women of childbearing age to notify prescriber immediately if pregnancy is suspected or known, as drug may need to be discontinued.

## flumazenil

**Anexate (CAN), Romazicon**

### Class and Category

*Pharmacologic class:* Imidazobenzodiazepine derivative

*Therapeutic class:* Benzodiazepine antidote

### Indications and Dosages

- *To reverse conscious sedation or general anesthesia from benzodiazepine therapy*

## I.V. INJECTION

**Adults.** 0.2 mg given over 15 sec, repeated after waiting 45 sec if response is inadequate and then repeated every 1 min, if needed, up to maximum dose. If sedation recurs, regimen is repeated every 20 min or more. *Maximum:* 1 mg given in 0.2 mg increments every 1 min over 5-min cycle repeated every 20 min 3 times for a total of 3 mg over 1 hr.
